CYCLOPÆDIA:

OR, AN

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

D.

D, The fourth letter in the alphabet, and the third consonant.

The letter *D* is the fourth in the Hebrew, Chaldee, Samaritan, Syriac, Greek, and Latin alphabets; in the five first of which languages it has the same name, though somewhat differently spoken, e. gr. in Hebrew, Samaritan, and Chaldee, *Dalath*; in Syriac *Dalath*; and in Greek *Delta*.

The Arabians have three *D's* in their language, the first called *Dal*, which is the eighth of the twenty-eight letters; the second, called *Dhāl*, is only distinguished from the former by having a point added over it; though its sound is much the same with that of the *Z*: the third, which is their seventeenth letter, is called *Da*, and pronounced like our *D*, though in form it resembles the Arabic *Ta*, the difference being a point added at the top. The form of our *D* is the same with that of the Latins; as appears from all the ancient medals and inscriptions. And the Latin *D* is no other than the Greek Δ , rounded a little, by making it quicker, and at two strokes. The Δ of the Greeks, again, is borrowed from the ancient character of the Hebrew *Dalath*; which form it still retains on the Samaritan coins, as is shewn by the Jesuit Soucier, in his Dissertation on the Samaritan Medals. All the alteration the Greeks have made in it, is the making it sloop a little, and taking away a little line. Nor would it be difficult to shew, that the Syriac *Dalath*, and the Arabic *Dal*, are both borrowed from the ancient Hebrew, as well as the $\daleth$ *Dalath* of the modern, or Chaldee Hebrew.

Some indeed will have it, that the Greek Δ , *Delta*, is borrowed from the Egyptians, who made their *D* of three stars disposed in a triangle; which was a hieroglyphic that among them denoted God, the sovereign Being, as if they had had some notion of a Trinity: but this surmise is weakly supported.

Grammarians generally rank *D* among the lingual letters, as supposing the tongue to have the principal share in the pronunciation thereof; though the abbot de Dangeau seems to have reason in making it a palatal letter. It has one uniform sound, nearly approaching to that of *T*, but formed by a stronger appulse of the tongue to the upper part of the mouth.

D is also a numeral letter signifying *five hundred*, which arises hence, that in the Gothic characters the *D* is half the *M*, or *CJ*, which signifies a thousand. Hence the verse:

Litera D velut A Quingentes significabit.

A dash added at the top of the *D*, denotes it to stand for *five thousand*.

D used in abbreviation has various significations: thus *D* stands for doctor, and *M.D.* doctor of medicine, Vol. II. N^o 89.

D. T. doctor of theology, *D. D.* doctor of divinity, or *doctus de diti*; *D. D. D.* is used for *dat, datat, dedit*; and *D. D. D. D.* for *dignum dei donum dedit*.

Among Roman writers, *D* stands for *devotus, decimus, devotus, debui, and distanti*.

D N in the Roman epitaphs signifies *diis manibus*, but on other occasions *dei magna, or dei magni*; *D N* denoted *dominus noster*, a title given by the Romans to their emperors.

D on the French coins is the mark of the city of Lyons.

D, in the chemical alphabet, signifies vitriol.

D, in the Italian *Musici*, intimates, that in thorough basses, the treble or descant ought to play alone; as *T* does the tenor, and *B* the bass.

DC, in the Italian *Musici*, an abbreviation of *da capo*, i. e. from the head or beginning; these words or letters are commonly met with at the end of rondells, or such airs and tunes as end with the first strain, and intimate that the song is to be begun again, and ended with the first part.

DAALDER. See **DOLLAR** and **COIN**.

DAB, in Ichthyology, a name given by the English to a small fish of the *PLEURONCTES* kind, called by authors the *passer asper* and *limanda*.

It is a flat fish, superior in goodness to the common plaice, but inferior in size, covered with small scales, rough at their extremities, and edged as it were with teeth: the eyes are on the right side, and are placed very close together. It is generally of an uniform brown colour on the upper side, though sometimes shaded with a darker; the lower part of the body is white. The lateral line is incurved at the beginning, and then proceeds straight to the tail. It is in best season in February, March, and April; spawns in May and June, and becomes fatty during the rest of summer. The *junco-dab* resembles the former; its back is covered with small smooth scales, of a light brown colour, and spotted with yellow; the belly is white, and marked with five large dusky spots. It is equally good with the common *dab*. Pennant.

It is caught in the Mediterranean and English seas.

DABUH, a name given by the Arabs to the *HYENA*.

DACE, in Ichthyology, the English name for the fish, called by authors the *leuciscus*. According to the new system of Artedi, this is a species of the cyprinus; and it is called by some *albicula*.

It is distinguished from other fishes by its resembling the chub in size, but that it is smaller and whiter, and has a smaller head in proportion to its body. Its length is seldom more than ten inches. It has no teeth in its jaws, but, like the rest of the leather-mouthed fishes, has them in the throat. It is very common in our rivers, and is a remarkably lively fish. They spawn in February, and the males at that time are spotted and scabby, as in the

A

redd,

trout, &c. and are in highest season for table in April and May; but they are never a very well-tailed fish, or much esteemed.

This fish gives the expert angler great diversion. The *Idai* will bite at any fly; but he is more than ordinarily fond of the stone-caddis, or May-fly, which is plentiful in the latter end of April, and the whole month of May. In warm weather this fish very seldom refuses a fly at the top of the water; but at other times he must have the bait sunk to within about three inches of the bottom. The winter fishing for *Idai* requires a very different bait: this is a white maggot with a reddish head, which is the produce of the eggs of the beetle, and is turned up with the plough in great abundance. A parcel of these put in any vessel, with the earth they were taken in, will keep many months, and are an excellent bait.

Small *Idai* may be put into a glass jar with fresh water, and there preserved alive for a long time, if the water be properly changed. They have been observed to eat nothing but the animalcula in the water. They will grow very tame, by degrees. Phil. Trans. N° 487. p. 23. 40.

DACOLITHUS, in Ichthyology, a name given by many to a small fish, a species of the loach, and distinguished by the name of *restitus barbatus antea* by Ray and others. It is a very small fish, seldom exceeding two, or at the utmost three inches in length. Its head is broader and flatter than the rest of the body; its back is of a dusky brown, spotted with black, and its belly yellow. It has two heads on each side of the upper jaw, and on the coverings of the gills has, on each side, two prickles, or a double-pointed sharp hook, by means of which it moves itself about among the stones. This fish loves shallow waters with a stony bottom, and spawns in May and June. Whillogby.

There is another species of this fish, which has ten barbs about its mouth, and otherwise resembles this. There is an opinion that they swallow little stones, and they have hence the German name signifying stone swallows, or stone-bizars.

DACRYODES, in Medicine, a term applied to ulcers, which are continually yielding a purid matter.

The word is formed from *δακρυον*, tears, and *δωσ*, form; denoting the ulcers to weep, or shed somewhat like tears.

DACRYON. See TEARS.

DACYLI, **DACYLUS**, a foot in the Latin and Greek poetry, consisting of a long syllable, followed by two short ones; as *carmina*.

Some say it is derived from *δακρυον*, a finger, because it is divided into three joints, the first of which is longer than the other two.

The *dacyle* is said to have been the invention of Dionysius or Bacchus, who delivered oracles in this measure at Delphos, before Apollo. The Greeks call it *επικρασις*. The *dacyle* and spondee are the most considerable of the poetical feet; as being the measures used in heroic verse by Homer, Virgil, &c. These two are of equal time, but not equal motion. The spondee has an even, strong, and heavy pace, like a trot; the *dacyle* resembles the nimble broken of a gallop.

DACYLUS was also a sort of dance among the ancient Greeks, chiefly performed, as Hesychius observes, by the athletes.

DACYLS also denote the fruit of the palm-tree, more usually called *dates*.

DACYLETHRA, or **DACYLITHRA**; *Digitals*, among the *Antient Physicians*, a medicine used to provoke vomiting. It was a sort of topical application, and is described at large by Orribasius.

DACYLI, in Antiquity, a name attributed to the first priests of the goddess Cybele; who were particularly called *Dacyle Idai*, on account of the goddess herself, who was styled *Cybele Idai*, because principally honoured on mount Ida in Phrygia. The name *Dacyle* is supposed to have been given them on this occasion: that to prevent Saturn from hearing the cries of Jupiter, whom Cybele had committed to their custody, they used to sing verses of their own invention, which by their unequal measures seemed to resemble the foot called *dacyle*.—This is the account of the grammarian Diomedes.

One Sophocles, quoted by Strabo, lib. 6. speaks differently. According to him they were called *Dacyle*, from the Greek word *δακρυον*, finger, because their number was at first equal to that of the fingers of the hand, viz. ten; five of them boys, and as many girls. He adds, that it is to them we owe the invention of iron, and the manner of working it, with divers other useful things. Others make their numbers more, and others less, than ten. Some, again, make them natives of Phrygia, near the foot of mount Ida; and others bring them from other places.

However, all the authors Strabo had seen, he says, agreed

that they were the first who wrought in iron; that they had been ministers of the mother of the gods, or Cybele; and that they dwelt at the foot of mount Ida; and they probably derived their knowledge of forging metals from the fusion of minerals at the burning of mount Ida. It is also conjectured by some authors, not that the Curetes and Corymbantes were the same with the *Dacyle Idai*, but that the Curetes and Corymbantes were their posterity; that a hundred men, born in Crete, were first called *Dacyle Idai*; that each of these had nine children who were the Curetes; and that each of the Curetes had ten children, who were also called *Dacyle Idai*. They were CYCLOPIANS.

Strabo only gives us the names of four of the *Dacyle Idai*, which are Salaminus, Damianus, Hercules, and Acton.

DACYLIC, something that has a relation to *dacyle*. Anciently, there were *dacyle*, as well as spondee flutes, *tibiae dacyle*. The *dacyle* flutes consisted of unequal intervals; as the *dacyle* foot does of unequal measures.

DACYLIC VERSES are hexameter verses, ending in a *dacyle* instead of a spondee; as spondee verses are those which have a spondee in the fifth foot instead of a *dacyle*. An instance of a *dacyle* verse we have in Virg. *Æn. lib. vi. 13*.

Bis patris cecidisse manu: quin proles annia Perigunt oculis—

DACTYLIOMANCY, **DACTYLIOMANTIA**, a sort of divination performed by means of a ring. The word is composed of the Greek *δακτυλος*, ring, of *μαντις*, finger; and *μαντις*, divination.

Dactyliomancy consisted principally in holding a ring, suspended by a fine thread, over a round table, on the edge whereof were made seven marks with the twenty-four letters of the alphabet. The ring in shaking, or vibrating over the table, stopped over certain of the letters, which, being joined together, composed the answer required.

But the operation was preceded and accompanied by several superstitious ceremonies; for first the ring was to be consecrated with a great deal of mystery: the person who held it was to be clad in linen garments, to the very shoes; his head was to be shaved all round; and in his hand he was to hold vervain. And before he proceeded on any thing, the gods were first to be appeased by a formula of prayers, &c. Ammianus Marcellinus gives the process at large in his twenty-ninth book.

DACTYLIS, in History. See *Cæli*'s-foot Grass.

DACTYLONOMY, **DACTYLOMIA**, from *δακτυλος*, finger, and *νομος*, law, the art of accounting, or numbering, by the fingers.

The rule is this: the left thumb is reckoned 1, the index 2, and so on to the right thumb, which is the tenth, and of consequence is denoted by the cypher 0.

DACYLUS, in Ichthyology, a name used by many authors for the faden or razor-fish, supposed to be the *dacyle* of Pliny, to which he attributes a quality of being luminous in the dark; but Mr. Reaumur has observed, that the common faden or razor-fish has no such quality; but that the *phalos*, or, as the French call it, the *dacyle*, has; and therefore it follows either that the *phalos* is the *dacyle* of Pliny, or else that this author has attributed to one species of fish what is the peculiar property of another. The shell of this creature is not at all luminous, but only its body and juices; and in this it is no way allied to some kinds of fish, which are known to have the quality of shining in the dark, since those never shine till they are in a state of decay, and in part rotten; whereas these have their luminous quality at all times, even when just taken out of the sea. The glow-worm has only part of its body luminous, but the *phalos* is luminous all over, and is equally so in every part: and when the fish is taken whole out of the shell, and laid in a dark place, every part of its surface shines with a very bright light. Neither is the light peculiar to the external surface of the fish, but common to the whole body: for if it be wounded transversely, or longitudinally, the cut parts are equally luminous with the other surfaces.

The *phalos* is therefore a true natural phosphorus, and, like the artificial phosphorus of urine, it renders every thing luminous that it is rubbed against.

Mr. Reaumur observed of this fish, that when fresh caught it abounds with water, and that this water naturally drops away in the handling it; and, according to Pliny's just observation, these very drops of water are luminous.

The light which this fish gives to bodies that touch it, is not of any long continuance, but remains only while they are wet. Mr. Reaumur observed, that the light upon his fingers grew fainter and fainter by degrees as they dried; and that on dipping them in water to wash them,

them, it brightened up again. This author was thus encouraged to attempt some way of keeping the fish, so as to make it a phosphorus ready for use at pleasure; but this did not succeed to his wishes.

In the summer months, the fifth may be kept several days fresh, and with their luminous property, but as they begin to decay, they gradually lose it. It is from also, that there being some dead once among the living, would make them lose their luminous quality even in that which is their bell flate. It is well known, that the RHINOLAS lives in holes within flones, from whence it cannot get out, and Mr. Beaumont causing some of these flones to be taken up, in which, on breaking, they appeared to be some dead ones, and some alive, found that the living fifth from these flones had not their luminous property, which seemed as it were extinguished by the dead and stinking ones. Mem. Acad. des Sciences. ann. 1722.

DACTYLUS *Idæus*, in *Natural History*, a name given by many authors to the BELEMNITES: supposed erroneously by many, to be the *Hyxarides* of the ancients. For other meanings of the word, see DACTYL.

DADO, in *Architecture*, is, by some writers, used for that part in the middle of a pedestal of a column between its base and cornice. It is of a cubic form, whence it is also denominatd *die*.

DADUCHI, in *Antiquity*, priests of Ceres.

That goddess, having lost her daughter Proserpine, say mythologists, began to make search for her at the beginning of the night. In order to do this in the dark, she lighted a torch, and thus set forth on her travels throughout the world: for which reason it is, that she is always seen represented with a lighted torch in her hand.

On this account, and in commemoration of this pretended exploit, it became a custom for the priests, at the festivals and sacrifices of this goddess, to run about in the temple, with torches, after this manner; one of them took a lighted torch from off the altar, and holding it with his hand, ran with it to a certain part of the temple, where he gave it to another, saying to him, *Tibi trade*; this second ran after the like manner, to another part of the temple, and gave it to the third, and so of the rest.

From this ceremony the priests became denominated *daduchi*, *ḏaduxi*, q. d. *torcularii*; from *ḏu*, an untwisted and religious wood, as pine, fir, &c. whereof the ancients made torches; and *exu*, *ḏhu*, *I hold*. The Athenians also gave the name *daduchus* to the high-priest of Hercules.

DEDALA, in *Antiquity*, two festivals in Boeotia, one of which was observed by the Platæans at Alalcomænus, where was the largest grove in all Boeotia. Here they assembled, and expando to the open air pieces of fiddlen fells, carefully observed whether the crows that came to feed upon them took their flight, and then hewed down all those trees on which any of them alighted, and formed them into statues, which by the ancient Greeks were called *dedalæ* and *andæ*.

The other solemnity was by far the greatest and most remarkable of the two, being celebrated only once in sixty years. For the ceremonies observed in it, see Pott. *Archæol. Græc.* lib. ii. cap. 20.

DÆDIS, among the Greeks, a solemn festival that lasted three days, during all which time *dædæ*, or *torches*, were kept burning, which gave occasion to the name. Poët. Archæol. Grec. lib. ii. cap. 20.

DÆMON. *Daemon*, a name the ancients gave to certain spirits, or genii, which they say appeared to men, either to do them service, or to hurt them.

The Greek word, *daimon*, is derived (according to Plato, in his *Cratylus*, p. 308, ed. Serrani, vol. i.) from *daimon*, knowing, or intelligent; but according to others from *dassueo*, to distribute. See the Scholiast on Homer, II. i. ver. 232. Either of these derivations agrees with the office ascribed to *daimoni* by the ancient heathens, as the spirits intrusted with the *inspiration* and *government* of mankind. For, according to the philosophers, *daimoni* held a middle rank between the celestial gods and men on earth, and carried on all intercourse between them; conveying the addresses of men to the gods, and the divine bequests to men. Plutarch, de Defect Orac. p. 415, et seq. Platon. Sympos. p. 202. tom. iii. ed. Serrani. Apuleius de Mro Socrate p. 674. 675. ed. Delph. Lamblicus de Mister. Auggu. de Civ. Dei.

It was the opinion of many, that the celestial divinities did not themselves interpose in human affairs, but committed the entire administration of the government of this lower world to their subaltern deities. *Nepos enim pro majestate quam celestium fuerit, hoc coram. Ampleius de Deo Socratis. p. 677. Conclia celi suum voluntate, nomine & auctoritate, seu demum obsequio, & opera, & ministeria fert, arborumque. id. ib. p. 675.* Hence they became the objects of divine worship. *If idols are no*

being, says Celsus, (apud Origen. cont. Cels. lib. viii. p. 303) what harm can there be to join in the public festival if they are demons, then it is certain that they are gods, in whom we are to confide, and to whom we should offer sacrifices.

Several of the heathen philosophers held, that there were several kinds of *dæmons*; that some of them were spiritual substances of a more noble origin than the human race, and that others had once been men. Apuleius de Deo Socratis, p. 682. 690. Ammonius apud Plutarch. de Defect. Orac. p. 421. tom. ii. ed. 1624. Plato in Timæo, p. 41. 42. 43. 44. 45.

But those *dæmons* that were the more immediate objects of the established worship amongst the ancient nations were human spirits, such as were believed to become *dæmons* or *devils* after their departure from their bodies. Hecate teaches (Vit. Kornul., p. 26, ed. Paris) that *every day is a day of nature and of life, the feast of virtuous men* are advanced to the rank of *dæmons*; and that from *dæmons*, if they are properly purified, they are exalted into gods, not by any artificial institution, but according to right reason. The same author says in another place (De lib. & Cl. p. 261) that *the Isis and Osiris were, for their virtue, changed from good dæmons into gods, as were Hercules and Bacchus afterwards, receiving the united honours both of gods and dæmons*. Hehob, or other poets, who have recorded the ancient history, or traditions, on which the public faith and worship were founded, assert, that the men of the golden age, who were supposed to be very good, became *dæmons* after death, and dispensed of good things to mankind.

to mankind. Though *dæmon* is often used in a general sense, as equivalent to a *deity*; and is accordingly applied to *fate* or *fortune*, or whatever else was regarded as a god, yet those *dæmons* who were the more immediate objects of divine worship amongst the heathens, were human spirits; as is shown in *Æneid* on *Miracles*, chap. iii. *l. 61*, &c.

The word *dæmon* is used indifferently, in a good and in a bad sense. In the former sense it was very commonly used by the Greeks, and is the meaning of the word *Meander*. *I think my father he was, careful of his life, but every god to be good. Never helms, those are certainly mislaken who affirm, that dæmons never signify an evil being till after the times of Christ.* Pylhagoras held demons who sent diseases to men and cattle. Diogen. Laert. Vit. Pylhagor. p. 574. ed. Amstel. Zelandus, in his preface to his Laws (apud Stobæum, Stron. 42.) supposes that an evil dæmon might be preface with a man, *to influence him to injustice.* The dæmon of Empedocles were evil spirits, and exiles from heaven. Plutarch. *Placit. p. 19. in Sen. Seneca.* And in his life of Diogen. (p. 938.) he says, *It was the opinion of the ancients, that evil dæmons were the cause of madness and lust, and that they were the cause of all diseases.* Scarce did an opinion more generally prevail in ancient times than this, viz. that as the departed souls of good men became good dæmons, so the departed souls of bad men became evil dæmons. See Chalcid. in Platon. Tim. cap. 125. c. 126.

It has been generally thought, that by *sheol* we are to understand *death*, in the Septuagint version of the Old Testament; but it has been shown, that the word is in that version certainly applied to the 'gulls of such dead men as the heathens deified, in Dent. xxxii. 17. Pl. cv.

Who is offered on this head is Mr. Farmer, in his Essay on the Demonicos of the New Testament, is much confirmed by what occurs in Sir Isaac Newton's Chronology, p. 260, 261. That *dæmoni* often bears the same meaning in the New Testament, and particularly in Acts xviii. 8. 1 Cor. x. 21. 1 Tim. i. 1. Rev. ix. 13. is shewn at large by Mr. Joseph Mede (Works, p. 623, & seq.) that the word is applied always to human spirits in the New Testament, Mr. Farmer has attempted to shew in the forementioned Essay, p. 208, & seq. As to the meaning of the word *dæmoni* in the fathers of the Christian church, it is used by them in the same sense as it was by the heathen philosophers, especially the latter Platonists; that is, sometimes for departed human spirits; and at other times for such spirits as had never inhabited human bodies. In the fathers indeed the word is more commonly taken in an evil sense, than in the ancient philosophers. Besides the two forementioned kinds of *dæmoni*, the fathers, as well as the ancient philosophers, have a third, viz. such as spring from the evil nature of the flesh, which they call *filii hominis*. In the theology of the fathers, there were in all sort kinds of *dæmoni*. Tertullian's Apology, cap. 23. Lactantius, Inst. Institut. lib. ii. cap. 15. Different orders of *dæmoni* had different stations, and employments assigned them by the ancients. Good *dæmoni* were considered as the authors of good to mankind; evil *dæmoni* brought innumerable evils both upon men and beasts. Amongst evil *dæmoni* there was a great difference

As long stamina inserted in the brim of the nectarium, terminated by oblong prostrate summits. They have a three-cornered obtuse germen, situated under the flower, supporting a long slender style, crowned by an obtuse stigma. The germen afterward becomes a roundish three-cornered capsule with three cells, filled with globular seeds. Linnæus enumerates seventy and Miller nine species.

DAGON, in *Mythology*, an idol of the Philistines represented under the figure of a man without thighs, with his body ending in the tail of a fish bending up backward, and covered with scales from the reins to the lower part of the belly. *Dagon* signifies fish in Hebrew. *Encycl.*

DAGENA, a marine animal with which the sea abounds, not twenty leagues from the coast of Spain, first discovered by Mr. Banks and Dr. Solander, who to this new genus of marine animals gave the name of *dagena*, from the likeness of one species of them to a geon. It is of an angular figure, about three inches long, and one thick, with a hollow passing quite through it, and a brown spot at one end, which they conjectured to be its stomach; four of these adhered together by their sides, when they were taken, and were thought at first to be one animal; but on being put in a glass of water they soon separated, and swam about briskly. Several specimens of them were taken, adhering together, sometimes to the length of a yard or more, and swimming in the water with very beautiful colours. But the colours of the *CARCINUS* sparrow were still more beautiful and vivid.

DAILE, in a ship, the trough wherein the water runs over the decks.

DAILY, in *astronomy*. See **DIURNAL**.

DAIRI, or *Dairio*, in the *History of Japan*, is the sovereign pontiff of the Japanese; or, according to Kammerer, the hereditary ecclesiastical monarch of Japan. In effect, the empire of Japan is at present under two sovereigns, viz. an ecclesiastical one, called the *dairi*, and a secular one, who bears the title of *shogun*. The last is the emperor, and the former the oracle of the religion of the country.

DAIRY, or *Dairy-house*, in *Rural Architecture*, a building where milk, butter, cheese, &c. are made or kept. See **MILK**, **BUTTER**, &c.

DAIS. See **DAISY**.

DAIS, in *Botany*, a genus of the *decidua maritima* class; the characters of which are, that it has a four-leaved involucrum, the corolla is divided into five parts, and the fruit is a single seeded berry. There are two species.

DAISY, in *Botany*, *Daisy*, a genus of the *frugifera polygama superflua* class. Its characters are these: it hath a radiated officious flower, composed of many hermaphrodite flowers in the disk, and female flowers, which form the border or rays, included in a common empolument. The hermaphrodite flowers have an oval germen, attended by five short stamina; the germen afterward becomes a single naked seed, placed vertically. There are three species; the first of which is the common *daisy*, which grows naturally in pastures; the second is a native of the Alps; the third is the garden *daisy*, of which there are several varieties. The garden *daisy* flowers in April and May, when they make a pretty variety, being intermixed with plants of the same growth: they should be planted in a shady border, and a loamy soil without dung, in which they may be preferred without varying, provided the roots are transplanted and parted every autumn; which, with keeping them from weeds, is all the culture they require.

The common little *daisy* has the reputation of being a very eminent medicine of the tribe of vulneraries. The roots and leaves are prescribed, fresh gathered, both externally and internally, in bruises and in wounds. They make a sort of cataplasim of the whole plant, bruised, in some parts of the kingdom, which they apply to the part, and give the juice internally at the same time. The ladies have an opinion also, that the roots of this plant have a power of stopping the growth of animals, and with this intent give a decoction of them in milk to the puppies of their favourite breed, to keep them small. The two species of *bellis* used in medicine are, the *bellis major*, called also *franchimontana vulgaris*, in English *cow-slip* *daisy*; and the *bellis minor*, called also *crispula minima*, or *symphytum minus*, of most repute for physical virtues, being esteemed a good stomachic, resolvent, healer, cooler, and astringent, efficacious against insensences of the blood, hemorrhages, &c.

Foreign dispensatory writers describe a water, syrup, conserve, essence, tincture, extract, and fixed salt, prepared from this plant.

DAISY, *her.* or *Globe DAISY*, *Globularia*, in *Botany*, a genus of the *pentandra monogyna* class. Its characters are these: it has a flower composed of many florets, which are included in one common feely empolument; and

each floret is tubulous, and cut into four parts at the tip. They have four stamina, terminated by distinct summits; and in the bottom of the tube is situated an oval germen, which becomes an oval seed, sitting in the common empolument. There are seven species.

This plant is to be found in the gardens of the curious; and is a vulnerary.

DAISY, *proat.* in *Botany*. See **CHAMOMILE**.

DAISY, *moder.* See **LEOPARD'S BAN**.

DAISY, *avog.* See **CORN MARYGOLD**.

DAKER, *her.* in *Ornithology*, the English name for the *irragis naira*, a bird of the gallinaceous kind, somewhat resembling the quail, and called by the Italians the king of the quails, *re della quaglia*. It is larger than the quail, and is common in Ireland, and in some of the northern counties of England. Ray. See **LAND-RAIL**.

DAKIN, in our statutes, is used for the twentieth part of a hilt of hides.

According to the statute of 31 Hen. III. *De consensibus pascuorum & messuagiorum*, a loft of hides consists of twenty *astirs*, and every *astir* of ten hides. But by 1 Jac. cap. 33. one loft of hides or skins is twelve dozen. See **DICKER**.

DALEA, in *Botany*. See **POREALA**.

DALECHAMPIA, so called in honour of Jacobus Dalechamp, a curious botanist, a genus of the *monadelphia class*. Its characters are these: it hath male and female flowers on the same plant; the male flowers have no petals, but many stamina. The female flowers have a roundish three-cornered germen, which afterward becomes a round three-cornered capsule, having three cells, each containing one roundish seed. We have but one species of this plant in England, which is a native of Jamaica. Miller.

DALMATICA, a garment with large open sleeves, worn at first only by bishops, though since made a distinction of degrees: it is so called, because it came originally from Dalmatia.

DALUS, in *Astronomy*, a certain measure of land; whence comes *dale*. The *dali prate* have been esteemed such near slips of pasture, as are left between the ploughed furrows in arable land; which, in some parts of England, are called *dals*. The word is applied in Welsh to low meadows by a river side.

DAM, a boundary or confinement, as to *dam up*, or *dam out*; *infra damnum suum*, within the bounds or limits of his own property or jurisdiction. *Bract. lib. ii. c. 37.*

DAMAGE, is generally taken for any hurt, or hindrance, that a man receives in his estate; but more particularly for a part of what the jurors are to enquire of, in passing verdict for the plaintiff, or defendant, in a civil action, be it personal or real. After verdict given of the principal cause, they are asked their consciences touching costs and damages, which contain the hindrance that the plaintiff or defendant hath suffered by means of the wrong done him by the defendant or tenant.

DAMAGE has two significations; the one proper and general, the other strict and relative. *Proper*, as it is in cases where damages are founded on the statute of 4 Hen. IV. cap. 1. and 8 Hen. VI. cap. 9. where costs are included within the word *damages*. *Damages* then, in its proper signification, is said *damenda*, when, by diminution, a thing becomes worse; and in this sense costs of suit are *damages* to the plaintiff, as by them his substance is diminished.

Relative is when the plaintiff declares the wrong done him to the *damages* of such a sum. This is to be taken relatively, for the wrong which passed before the writ brought; and is assessed by reason of the trespass *alors* said; and cannot extend to the costs of suit, which are future, and of another nature.

DAMAGES, *her.* *Damna Curiarum*, was a fee allotted out of all *damages* exceeding five marks, and recovered in the courts of common pleas, king's bench, and exchequer, which the plaintiff was obliged to pay as a gratuity to the prothonotaries and his clerks, for drawing special writs and pleadings; but is abolished by stat. 17 Car. II. cap. 6.

DAMAGE *spont.* or *volunt.* is when a stranger's herds are doing hurt, or spoiling the grain, corn, woods, &c. of another man, without his leave or licence. In this case, the party whom they damage may distrain, and impound them both by night, and by day; though in other cases, as for rent, services, &c. none may distrain in the night.

DAMASCUS *her.* a very fine kind of steel, made in some parts of the Levant, and particularly at Damascus, remarkable for its excellent temper; and used chiefly in the making of sword-blades.

Some authors affirm us it comes from the kingdom of Golconda in the East Indies; where the method of tempering with alum, which the Europeans have never been able to imitate, was first invented.

DAMASK, a sort of filken stoff, having some parts raised above the ground, representing flowers or other figures. *Damasks* should be of dressed filks, both in warp and woof. It has its name from its being originally brought from Damascus, in Syria.

There is also a stuff in France called the *eastern damask*, made in imitation of the *east damask*, having the woof of hair, coarse filk, thread, wool, or cotton. Some have the warp of silk, and the woof of thread; others are all thread, or all wool.

DAMASK is also a kind of wrought linen, made in Flanders, is called, because its large flowers resemble those of *damask*. It is chiefly used for tablets: a table-cloth, and a dozen of napkins, are called a *damask-table*.

DAMASKEENING, the art, or act, of adorning iron, steel, &c. by making incisions therein, and filling them up with gold or silver wire; chiefly used in enriching sword-blades, guards and grips, locks of pistols, &c. Its name shews the place of its origin; or, at least, the place where it has been practised in the greatest perfection, viz. the city of Damascus in Syria: though M. Felibien attributes the perfection of the art to his countryman Curfinet, who wrought under the reign of king Henry IV.

Damascening is partly mosaic work, partly engraving, and partly carving; as mosaic work, it consists of pieces inlaid; as engraving, the metal is indented, or cut in *creux*; and as carving, gold and silver are wrought therein in relief.

There are two ways of *damascening*: in the first, which is the most beautiful, the brittle cut into the metal with a graver, and other tools proper for engraving on steel; and afterwards fill up the incisions, or notches, with a pretty thick filer or gold wire. In the other, which is only superficial, they content themselves to make hatchures, or strokes, across the iron, &c. with a cutting-knife, such as is used in making of small files. As to the first, it is necessary the gravings or incisions be made in the dove-tail form; that the gold or silver wire, which is thrust forcibly into them, may adhere the more strongly. As to the second, which is the more usual, the method is thus: having heated the steel till it changes to a violet, or blue colour, they hatch it over and across with the knife, then draw the design, or ornaments, intended, on this hatching, with a fine brass point, or bodkin. This done, they take fine gold wire, and conducting or chasing it according to the figures already designed, they sink it carefully into the hatchures of the metal with a copper tool.

DAMASSIN, a kind of damask, with gold and silver flowers, made in warp and woof, of wrought, and not raw silk.

DAMASSONIUM, in *Italy*. See *Star-lead*, & *water-blaster*.

DAMASQUITE, a kind of stuff made at Venice, of which there are two sorts; one with gold, the other with silk: the pieces are eighteen ells long. See *Lewis's* Com. Phil. Techn. p. 226.

DAMATER, in *Mythology*, the surname of Ceres.

DANATRIUS, in *Ancient Chronology*, the Egyptian name of the Athenian month *Panegyris*, which was the fifth of their year, and corresponded to the latter part of our October, and beginning of November. See *PYANETION* and *MONTH*.

DAME was formerly a title of honour, and is still used in the English law to denote a lady; but in common acceptation it signifies the mistress of a family of the lower rank in the country.

DAME's Feels. See *VIOLET*.

DAMELOPPE, a kind of *BILANDER* used in Holland, for conveying merchandise from one canal to another, and contrived for commodious passages under the bridges.

DAMIANISTS, a branch of the ancient Accephalous Severians; who agreed with the Catholics in admitting the fourth council; but disowned any distinction of persons in the Godhead, and professed one single nature incapable of any difference, and yet they called God, the Father, Son, and Holy Ghost. On which account the Severian Petrine, another branch of Accephali, used to call them Sabellianists, and sometimes Tetrastites. Thus much we learn from Nicephorus Callistus, lib. xviii. cap. 40. They took their name from *Damianus*, a bishop of Alexandria, who was originally their leader, in the fifth century.

DAMIER, in *Ornithology*, the name given by French naturalists to that elegant species of vulture, the spots of which stand in a chequered order, and resemble the marks of a draught or chess board, that being the common signification of the word *damier*. See *VOLUTA*.

DAMNATA terra in *Chemistry*, the same with *CAVUT materia*.

DAMPS, in *Natural History*, are noxious steams, or exhalations, frequently found in close, subterraneous places, particularly mines, pits, and wells.

In the German and Saxon languages the word *damp* signifies vapour and exhalation.

Damps, with respect to their nature and effects, may be distinguished into two kinds: the *first* is heavier than common air, and therefore chiefly lies at the bottom of pits and mines. It extinguishes flame, precipitates the lime of lime-water, and is noxious, and often fatal to animals, and on this account called the *stink-damp*. It is a species of *fixed air*, and has been described by modern writers under that name. It resembles those inflammable vapours, that are produced by the combustion of inflammable bodies, as charcoal, and by fermenting and efferevescing substances. This *damp* is sometimes visible, and appears in form of a fog, as in a cavern near Pyrmont, and it hangs so near the surface, that a person may stand upright, without any other inconvenience than an uncommon heat of his lower extremities, but he cannot without danger bend down his head. Many instances occur of the fatal effects of this kind of *damp*. Some persons, digging in a cellar at Paris, were found dead, stiff as statues, with open eyes, and in the posture of digging. Several others were successively destroyed at Chartres, by going down into a cellar where a baker had been accustomed to throw his embers from his oven; and one, who was instantly killed upon being let down into it, was opened, his lungs were found spotted with black marks; his intestines swollen, red, and inflamed; and the muscles of his legs, thighs, and arms, seemed to be separated from each other, and from the adjacent parts. This case was so singular, that it drew the attention of the magistrate and physician, who found that the embers had not been properly extinguished, and that they had raised a malignant vapour from the fat-petre, with which the cellars in that neighbourhood abound. A quantity of water was thrown in to extinguish the fire, and lay the vapour, and thus the danger was removed. Hist. de l'Academie des Sciences, 1701, 1710, and Connon's Differt. Med. Phil.

Miners try the salubrity of the air in pits where they work, by carrying down with them a lighted candle; they soon discover the effects of the noxious vapour in its diminishing, and gradually extinguishing the flame; however they remain safely for several hours in pits where a candle cannot burn; but when the *damp* is so strong, that not only the flame of the candle, but also the redness of the burning wick is extinguished, they never venture to remain a minute, knowing that such a degree of *damp* will be soon fatal to animal life.

The *second* kind of noxious vapour, though less dangerous than the former, is called the *burning*, or *fire-damp*; because, when touched by the flame of a candle, it takes fire, and explodes like gunpowder. This is chiefly found in coal-mines, and sometimes in lead-mines, or in those of Mendip-hills. It is lighter than common air, and therefore flows near the roofs of subterraneous places; and miners, when it is accidentally inflamed, or when they designedly set fire to it, in order to destroy it, lie flat on the ground, and thus escape injury. This inflammable vapour may probably be produced by the decomposition of pyritous matters, with which most mines, and especially coal-mines, abound.

In some of the tool-pits in the neighbourhood of Mendip hills, *fire-damps* almost continually happen, so that great numbers have been killed, maimed, and burnt by them. The colliers however continue their work notwithstanding, only using the caution of renewing their air very quick, and using no candles in their work but those of a single wick, and of fifty or seventy to the pound; which notwithstanding will give as good a light there, as others of ten or twelve to the pound in other places. They always have the caution to place even these behind them, and never present them to the breast of the work. When any person is burnt by these *damps*, they presently betake themselves to a good fire, and sending for a large quantity of cows milk, they bathe the burnt places with this white wash; and afterwards the places will heal by the common cooling ointments, and healing plasters.

The German miners think themselves not qualified for their business, if they are not able to make their weather, as they express it, that is, to cure their *damps*. These are of various kinds in their mines; some so strong that they suffocate the workmen, others less violent, and only making them faint, without doing them any further hurt, unless they are so impudent as to continue a long time in the place. The common way of curing the *damp* is by letting the air in and out, and causing a circulation in it. Phil. Trans. abr. vol. ii. p. 373, 382.

The pernicious *damps* in mines shew abundantly that nature affords us inflammable air in some cases; and we have found by experiments that art can do the same, and that very probably on the same principles with the natural. Sir James Lowther having collected the air of some

of these *damps* in bladders, preserved it so well, that, when brought up to London, it would take fire at the flame of a candle, on being let out by the orifice of a piece of tobacco-pipe.

It is well known to all that are versed in chemical experiments, that most metals emit a great quantity of sulphureous vapours during the effervescence they undergo in the time of their solution in their respective menstrua. On this principle may have produced an inflammable air by art, like the natural one. It is observed that iron, while under solution with oil of vitriol, emits a very great quantity of these vapours, which are very subtle, and not easily condensed. This vapour being received into bladders, in the same manner with the natural air of Sir James Lowther, took fire in the same manner, on being let out in a small stream, and answered all the phenomena of the natural kind. See *AIR fixed*, and *AIR inflammable*. There is a vapour called the *pearl-damp*, on account of its smell. It always comes in the summer-time, and hath never been known to be mortal. The miners in the Peak of Derby fancy that it arises there from the multitude of red trefoil flowers, called by them honeyuckles, with which the lime-stone meadows of the Peak much abound; the smell of this gives timely notice to get out of the way.

DAMSEL, **DAMISSEL**, or **DAMOISEAU**, an appellation anciently given to all young people of genteel or noble extraction of either sex, e. g. to the sons and daughters of knights, barons, and even of kings.

Thus, in history, we read of the *damsel* Popin, *damsel* Louis le Gros, *damsel* Richard, prince of Wales. Pasquier will have the word a diminutive of *dame*, an ancient name for lords; as in some authors we read *Dam Dieu* for Lord God; *dam* chevalier, &c. Though in its feminine sense he takes it to come from *dame*. Others derive the word from *dameville*, or *dameville*, a diminutive of *dominus*, *quasi parvus dominus*; accordingly, Du Cange observes, that it has been sometimes written *damore*.

They who hold the *feignery* of Commaire, M. de la Roque tells us, anciently held it in the title of *damefey*: and M. de Marca affirms us, that the nobility of Bern is still divided into three bodies, or classes: the barons, the cavers, and the *damsels*, *doncellis*, called in that country *damorens*.

The kings of Denmark and Sweden have the same title, as appears from Panton's Hist. of Denmark, lib. vii. and viii. and Henry of Upsal's Hist. of Swe. lib. iii. From the sons of kings, the appellation passed to those of great lords and barons; and, at length, to those of gentlemen who were not yet knights.

DAMSEL, at present, is applied to all maids, or girls, not yet married, provided they be not of the lowest class of people.

DAMSEL is sometimes also applied to a kind of utensil put in beds, to warm old men's feet.

It consists of a hot iron inclosed in a hollow cylinder, which is wrapped round with linen cloth, and keeps its warmth a long time. Some call it a *nan*.

DAMSON *tree*, in *Botany*. See *CHRISTOPHYLOM* and *PRUNUS*.

DAMSONS. See *PRUNUS*.

DANAL, or **DANACE**, *coin*, or *BARAN*, in *Antiquity*, a coin current among the barbarians, being somewhat more than the *OBOLUS*. This they put into the mouths of dead people, to pay for their passage over the river Acheron.

DANAIDES, in the *Ancient Mythology*, the daughters of Danais, or Danaus, eleventh king of Argos, and brother of Egyptus.

They were fifty in number, and were espoused to the fifty sons of their uncle Egyptus.

Danaus, fearing the accomplishment of an oracle, which had foretold, that he should be expelled his kingdom by a son-in-law, persuaded his daughters to murder, each of them, her husband, the first night, which they performed, all but Hypermnestra, who spared her husband Lynceus.

In vengeance for this crime of the forty-nine *Danaides*, the poets have condemned them to hell, to be continually employed in filling a cask perforated at bottom.

The *Danaides* are sometimes also called *Belides*, from their father, who was the son of the Egyptian Belus. Hyginus has preserved the names of forty-seven of them.

DANCE, an agreeable motion of the body, adjusted by art, to the measures of a piece of music, either sung or played.

The word is French, *dance*, formed of the German *dant*, or *danz*, which signifies the same thing. Bochart derives it from the Arabic *danza*, and Guichart from the Hebrew *ḏāṭ*, *dant*, which have all the same signification. II. N. 90.

tion. Salmastius derives the French *danser*, to dance, from the Latin *dansare*, in thickens; as holding it a practice among the ancient fullers to leap and dance as they fulled their cloths.

Some distinguish the *high dance*, consisting of capers, gambades, &c. from the *low dance*, which is the *terra a terra*, or close to the ground.

In the carousal of king Louis XIII. there were *dances* of horses. The invention of such *dances* is attributed to the Sybarites.

Dancing has always been in use among all nations, both civilized and barbarous; though held in esteem among some, and in contempt among others. Of itself, no doubt, dancing is harmless. There is a time, says the preacher, to dance; and sometimes it is even made an act of religion. Thus David danced before the ark, to honour God, and expels his excess of joy for its return into the city of Zion. The daughters of Shileh are likewise said to have danced in a yearly feast of the Lord. Judges, ch. xxi. And we find many references to this practice in the religious solemnities of the Jews. From them it passed to the Egyptians, and afterwards to the Greeks and Romans, with whom it was a principal part of the worship of their false gods. It afterwards was adopted in many pagan nations; and Christians in popish countries celebrated certain festivals, particularly those of the sacrament, and passion of our Lord, with dancing. Socrates learnt to dance of Alpina. And the people of Crete and Sparta went to the attack *dancing*. On the other hand, Cicero reproaches Gallistius, a singular man, with having danced. Thibault expelled the dancers out of Rome; and Domitian excluded several members from the senate, for having danced. Cato and Pollux are said to be the first who taught the art of dancing; and that to the Lacedaemonians: though others attribute the invention to Minerva, who, they say, danced for joy after the defeat of the giants.

The ancients had three kinds of dances, called *harolles*, the first grave, called *amphibia*, answering to our *low dances* and pavanes. The second gay, called *carolus*, answering to our *canzons*, galliards, gavots, and vaults.

The third, called *fauvins*, was a mixture of gravity and gaiety. Neopolemus, son of Achilles, taught the Cretans a new sort of dance, called *Pyrrhia*, or the *armed dance*, to be used in going to war: though, according to mythologists, the Curetes first invented this dance, to amuse and divert the infant Jupiter, and to drown his cries with the noise and clash of their weapons, beating against their bucklers.

Diodorus Siculus, in the fourth of his Bibliotheca, assures us, that Cybele, daughter of Menoeus, king of Phrygia, and Dindymeneis his wife, invented divers things, and, among others, the flageolet of several pipes, *dancing* the tabor, and the cymbal. Numa, it is certain, instituted a sort of dance for the flail, priests of Mars, who made use of weapons therein. From these dances were composed another sort, called *falsitas minicorum*, or the *hustlers dance*; wherein the dancers were dressed in little corsets, with gilt morions, and had bells on their legs, and swords and bucklers in their hands. Lucian has an express treatise, and Julius Pollux a chapter, on this head; Athenaeus, Ocellus Rhodiginus, and Scaliger, also make mention of this dance.

It is not many years ago, since Thoinet Arbeau, a dancing-master of Paris, gave an orthography, wherein all the steps and motions of a dance are written, or noted down; as the sounds of a song are scored in music: though the famous Beauclaus had some pretensions to be the inventor of this secret, and accordingly procured an arrest in his favour.

Dancing is usually an effect and indication of joy among most nations: though M. Pallerat assures us, that there are people in South America, who dance to shew their sorrow; and it likewise made a part of the funeral solemnities of the ancients.

DANCE of *St. Vincent*. See *VITUS*.

DANCE, *Country*. See *COUNTRY-DANCE*.

DANCER, *Reps*, *Schneiders*. Groddeck, professor of philosophy at Dantzig, has published a dissertation on *reps-dancers*, De Funambulis; full of learning, and an uncommon knowledge of antiquity. He defines a *reps-dancer*, a person who walks on a thick rope fastened to two opposite posts; which is precisely what is expressed by the Latin word *funambulus*. But our *reps-dancers* do more; for they not only walk, but dance and leap upon the rope.

The ancients, it is certain, had their *reps-dancers* as well as we: witness the Greek words, *neurobates*, and *fibistobates*, as well as the Latin *funambulus*, which every where occur. They had likewise the *cremnobates* and *orbates*, that is, people who walked on the brink of precipices. Nay more, Suetonius in Galba, cap. 6. See

heca in his eighty-fifth epistle, and Plooy, lib. viii. cap. 2. make mention of elephants that were taught to walk on the rope.

Mrs. Goodluck, coming from the historical to the moral consideration, maintains, that the profession of a *repentant* is not lawful; that the professors are infamous, and their art of no use to society; that they expose their bodies to very great dangers; and that they ought not to be tolerated in a well-regulated state. But, coming afterwards to temper the severity of his morals, he allows that there are sometimes reasons for admitting them; that the people must have laws; that one of the secrets of government is to furnish them therewith, &c.

The ancient *repentants* had four several ways of exercising their art; the first, vaulted, or turned round the rope, like a wheel round its axis, and there hung by the heels, or the neck. The second flew, or slid, from above downwards, resting on their stomachs with the arms and legs extended. The third ran along a rope stretched in a right line, or up and down. Lastly, the fourth not only walked on a rope, but made surprising leaps and turns thereon.

DANCERS, in *Eccelesiastical History*, a sect that sprung up in A.D. 1146, in 1272, and spread through Flanders. Persons of both sexes were suddenly seized with dancing fits, and continued them, with excessive violence, till they were quite exhausted; and at these times they pretended to receive wonderful visions. The French preachers, or convulsionists, in later times, and some wild enthusiasm in our own country, resembled these more ancient religious dancers.

DANCELE, in *Herbals*, is when the outline of any bodice, or ordinary, is indicated very largely; the large neck of the indenture being the only thing that distinguishes it from indenture.

There is also a bearing of a bend, called *dancele*; and thus, he beareth azure, a bend double *dancele* argent.

DANCHE, or *Dancie*, in *Herbals*, the same with indenture; or, as others will have it, with *dancele*.

DANCETIA, in *Botany*, a name given by the people of Guinea to a plant which they use in disorders of the head, boiling it in water, and using the decoction in the way of a fomentation. It is a species of bindweed, and is called by *Peterson* *Convolvulus guineensis* *foliis ovatis* *semito*, at the five-leaved Guinea bindweed, with leaves not serrated. *Celsus* mentions, in his *Prodomus*, delicate species of bindweed growing in Egypt, which exactly agrees with this in all particulars, except that it is lately termed all round the edges of the leaves. *Philop.* N. 8. p. 2.

DANDELION, *Helianthus*, or *Leontodon*, in *Botany*, the name of a genus of plants of the *pyrenaeae* *polygamia* *apetalis* class, the characters of which are these: the flower is of the first-dioecious kind, and the petals it is composed of six placed on the embryo seeds, and surrounded by the cup; the embryo finally becomes fringed with down, which are altered to the thalamus, but expand their downy ends into a globular head, and the stalks are usually hollow, and not branched.

Müller gives no characters of this genus; and only observes, that they grow naturally in the fields, that they are a troublesome weed, which should be destroyed before the seeds ripen, as by reason of their down they are wafted by the wind to a great distance and that the roots are gathered by some people, and blanch'd in their gardens for a salad herb.

The common species of this plant has much the same virtues with the common endive, but in a greater degree: the roots eaten in spring are esteemed of great service to obstructions in the liver and spleen. In more immediate sensible operation it is to loosen the belly, promote the urinary discharge, and render the water high-coloured, without exciting any particular heat.

DANEMARK, or *Scania*, See *ELDER* and *FAULDS*.

DANEGLIA, or *Danegeld*, from *Dane* and *gold*, signifying in Danish, silver, an annual tax laid on our ancestors, full of 10. afterwards 20. for every hide of land through the realm, for maintaining such a number of forces as were thought sufficient to clear the Britons of Danish pirates, which sometimes greatly annoyed our coasts.

It was first imposed as a standing yearly tax on the whole nation, under King Ethelred, A. D. 991. *Thurpin* says, Canute, King of the Danes, to procure his peace, was compelled to charge his people with heavy taxes, called *dane-geld*. At first they paid 10,000. then 16,000. then 24,000. after that 30,000. and lastly, 40,000. *per annum*.

Ethelred, in 1002, made a vigorous effort to free his people from this infamous tribute, by a general tax on all the lands of his kingdom, for raising out a fleet, which might effectually guard against the Danes. Lord Lytelton's History, &c. &c. in p. 65.

Edward the Confessor remitted this tax: William I. and II. assumed it occasionally. In the reign of Henry I. it was accounted among the king's flagrant revenues; it was levied by King Stephen, and paid in the 11th, 20, 20th, and 21st years of Henry II. Soon after the name was lost. No church or church land paid a penny to the *dane-geld*; because, as it set forth in an ancient Saxon law, the people of England placed more confidence in the prayers of the church, than in any military defence they could make. *Camd. ap. Magn. Brit. p. 68.*

DANIELAGE. See *LAW*.

DANGCANGHAG, in *Natural History*, the name given by the people of the Philippine islands to the heron. The Spaniards call it *ganza*. It is the same species with that so common in Europe. See *HERON*.

DANGERIA, in *Antiquity*, a payment in money made by foreign tenants, that they might have liberty to plough and sow in time of *PARNAX*.

DANIEL, or *Ben-Danania*, a canonical Book of the Old Testament, so denominated from its author Daniel, who was a very extraordinary person, and was favoured of God, and honoured of men, beyond any who lived in his time. His prophecies concerning the coming of the Messiah, and the other great events of after-times, are so clear and explicit, that, as St. Jerome tells us, Paraphrase objected to them, that those which related to the kings of Syria and Egypt, chap. xi. must have been written after the times of Antiochus Epiphanes; whereas this prophecy was translated into Greek a hundred years before his time, and the translation was in the hands of the Egyptians, who had no great kindness for the Jews, and their religion. And those prophecies foretelling the successes of Alexander, chap. viii. &c. were known to Alexander by the Jews, in consequence of which they obtained several privileges from him. *Ant. lib. xi. c. 8.* The style of Daniel is not so lofty and figurative as that of the other prophets; it is clear and concise, and his narrations and descriptions simple and natural: in short, he writes more like a historian than a prophet.

The Jews do not reckon Daniel among the prophets; part of his book, that is, from the fourth verse of his second chapter, to the end of the seventh chapter, was originally written in the Chaldean language; the reason of which was, that in that part he treats of the Chaldean-Babylonian affairs: all the rest of the book is in Hebrew. The six first chapters of the book of Daniel are a history of the kings of Babylon, and what befel the Jews under their government. In the six last he is altogether prophetic, foretelling not only what should happen to his own church and nation, but events in which foreign princes and kingdoms were concerned.

DANK, in *Commerce*, a piece of silver current in Persia, and in some parts of Arabia, weighing the sixteenth part of a drachm. It is also a weight used by the Arabians to weigh jewels and drugs.

DANTELE, in *Herbals*, the same with *dancele*, or rather with *danegeld*, viz. a large open indenture. See *DANCELE*.

DANTEZIGERS, or *Prussians*, in *Eccelesiastical History*, a sect of the refined ANABAPTISTS (see *FLUMINGIANS*), so called, on account of their adopting the manners and discipline of the Prussians.

DAPHNE, in *Botany*, a kind of divination, taken from the cracking of laurel leaves thrown into the fire.

DAPHNE, in *Botany*. See *SPURGEON-BAY*.

DAPHNELAON, in *Medicine*, *Daphnol* (from *daphnē*, the bay-tree, and *laon*, still, lasting, or oil of bay). This is prepared of the berries, when full ripe and ready to fall off, by boiling them in water; by which they transmit through their bulk a fat substance, which, after compressing the berries with the hand, is taken off with a shell. Some, after they have infused oil of turpentine with capsaic, juniper, cedar, and balsam, cut therein the tender leaves of the bay, and bind them together, and others add the berries, until it finally softens strongly; and sometimes styrac and myrror are mixed with them. The mountainous and broad-leaved bay is the fittest for the preparation of this oil, which is best in its kind when recent, of a green colour, very limy, and acrimonious.

Leucosm has heating and mollifying virtues, opens the mouths of the vessels (*arteries*), and removes obstructions. It is beneficial in all nervous disorders, pain and distillations of the ears; and is inferior to no other remedy in distempers of the kidneys, contracted from cold, the parts being anointed with it; but taken inwardly, it excites a nausea.

DAPHNEPHORIA, *Daphnephoria*, in *Antiquity*, a novel festival, celebrated by the Romans in honour of Apollo. For the ceremonies used at this solemnity, see *PORT ARCHEOL*.

DAPHNUS *apici*, in *Natural History*, the name of a Bone, the veins of which represent the grain of the wood of the

the bay-tree; and which was probably formed of the wood of that tree, impregnated with stony matter, in the manner of the other fossil woods.

DAPHNOMANCY, from *daphnē*, laurel, and *manteia*, divination; a kind of divination practised by throwing branches of laurel into the fire: the crackling of them was deemed a favourable omen; the contrary, otherwise. The leaves of laurel were also chewed, in order to communicate the gift of prophecy.

DAPIFER, the dignity or office of grand master, or grand fever, of a king or prince's household.

The word is pure Latin, compounded of *dapi*, *daps*, a dish of meat served on the table, and *fero*, I bear: so that *dapifer* literally signifies a *dish-carrier*, or an officer who serves the meats upon the table.

The title of *dapifer* was given by the emperor of Constantinople to the earl of Rossia, as a testimony of favour. In France, the like office was instituted by Charlemagne, under the title of *dapifer*, and *seneschal*; to which was added the superintendence over all the officers of the household.

In England the office of *dapifer* was less eminent; being found in several of our ancient charters named one of the staff of the officers of the household.

The dignity of *dapifer* is still subsisting in Germany. Till the year 1623, the elector Palatine was *dapifer* or grand fever of the empire: since that time, the elector of Bavaria has assumed the title of *archidapifer* of the empire. His office is, at the coronation of an emperor, to carry the first dish of meat to the table on his back.

The several functions of a *dapifer* occasioned the ancients to give him divers names: as, *dapifer*, and *seneschal*, *dispensator*, *convivator*, *trapezopos*, *archidapifer*, *fragilis*, *procurator*, *domestica*, *magistralis*, *accensus*, *inordinatus*, *insolentia*, *libalis*, *gastricus*, *affluens*, *praefectus* or *praepositus* *curiae*, *princeps equorum*, &c. *magister*.

DAPIFERAT, **DAPIFERAT**, the office of *DAPIFER*.

DAPPLE, in, in the *Manège*, is used for a horse which has marks of a dark bay colour. Such are also called *bay mirrors*.

DAPPLE, *black*, in the *Manège*, a black horse, having spots or marks blacker and more shining than the rest of his skin.

DAPSILES, *crowns*, among the Romans, a kind of crowns or garlands worn by the women, which covered their faces, and fastened as a veil.

DARANI, in the *Materia Medica*, a word used by some of the old writers in express of the *fel autumnale* of those times, which was the same with our *fel pecorum*.

DARAPTI, in *Logic*, a mode of syllogism in the third figure, wherein the major and minor are universal affirmative propositions, and the conclusion a particular affirmative. L. g.

DA Every truly religious man is virtuous.

RA Every truly religious man is hated by the world.

FTI Therefore, true virtuous men are hated by the world.

DARDANARIUS, *Uxor, Metaphor*; a name anciently attributed to such as acted a lewdry, and dardness of provisions, particularly corn, by buying and hoarding it up, to raise its value, and sell it again at an extravagant rate.

The name *Dardanarius* was given from one Dardanus, who is said to have made a practice of spoiling and destroying the fruits of the earth by a sort of lewdry. Hof. Lex. in voc.

The same people are also called *arsifratres*, *disfartari*, *fratellari*, *one* and *separatari*, and *separatari*.

DARE, See **DACE**, and **FIGURE**.

DARIC, in *Antiquity*, a famous piece of gold, first coined by Darius the Mode about 338 years before Christ; probably during his stay at Babylon, one of the vast quantity of gold which had been accumulated in the treasury. From thence it was dispersed over the East, and almost Greece; so that the Persian *daric*, which was also called *staty*, was the gold coin best known in Athens in ancient times. According to Dr. Bernard, it weighed two grains more than one of our guineas; but as it was very fine, and contained little alloy, it may be reckoned worth about twenty-five shillings of our money. Plutarch informs us, that the *daric* were stamped on one side with an archer clothed in a long robe, and crowned with a spiked crown, holding a bow in his left hand, and an arrow in his right; and on the other side with the effigies of Darius. All the other pieces of gold of the same weight and value; that were coined by the succeeding kings both of the Persian and Macedonian race, were called *daric*, from Darius, in whose reign this coin commenced. Of these there were whole *series* and half *darics*; and they are called in those parts of Scripture written after the Babylonish captivity, *adarjans*; and by the Talmudists, *dorimith*. Grayes says that the

daric is still found in Persia; but it is certainly very scarce, and perhaps of doubtful antiquity. Suidas in *Asiaticis*. Bernard de Ponder. Sec. p. 171. Pridcaux's Conn. vol. i. p. 182, &c.

DARII, in *Logic*, a mode of syllogism in the first figure, wherein the major proposition is an universal affirmative, and the minor and conclusion particular affirmatives. L. g.

DA They who speak well of every body have many friends.

RI Some speak well of every man.

I Therefore some have many friends.

DARK, *chamber*. See **CAMERA obscura**.

DARK, *lens*, a portable camera obscura, made not unlike a desk, and fitted with optic glasses, to take prospects of landscapes, buildings, fortifications, &c. See **CAMERA obscura**.

DARNEL. See **CRASS**.

DARREIN, in *Law*, a corruption of the French *derrière*, *last*, and used in the like sense, as *darwin* continuance (see **CONTINUANCE**); *darwin* presentment (see **ASSISE darwin presentment**).

DARSINI, in the *Materia Medica* of the ancients, a name given by some to cinnamon. It is generally used by Avicenna, Serapion, and the rest of the Arabian physicians.

DARSIS, in *Medical Writers*, is used for an excoriation of the skin. *Blancard*.

DART, in *Astronomy* and *Geometry*. See **SAGITTA**.

DARTOS, or **DARTUS**, in *Anatomy*, the musc coat of the scrotum, composed of a great number of muscular or fleshy fibres; whence some consider it as a cutaneous muscle. Dr. Hunter says no such muscle can be found, and Albinus takes no notice of it in his tables.

The word is pure Greek *dartos*, *excavatus*, *scab. matris*, of *daps*, *corrus*, probably because it lies clear under the skin, or from its excavated appearance.

It is by means hereof that the scrotum is contracted, or corrugated, which is esteemed a sign of health.

The *dartos* was anciently taken to be a continuation of the *peniculus scrotalis*, but mistakenly. It has several veins and arteries. It invests the testicles, and extending itself between them, separates them from each other. It is placed between two cellular membranes, which communicate with each other. See **SCROTUM**.

DARTU, in *Botany*, a name given by Avicenna and Serapion to a species of turpentine-tree, which the later authors call the *quercu*. This grew up to a very large tree, and bore a much larger and more beautiful fruit than the common turpentine-tree.

DASYMANIA, a superficial inequality of the inner part of the eye-lid, accompanied with a redness. *Blancard* derives it from *darsis*, *vergetus*.

DASTYUS, in *Zoology*, belongs to the order of brutes and class of *mammalia* in the Linnaean system. This genus has many grunting teeth, but no cutting per canine teeth. The several varieties are distinguished by the number of bands which encompass it, and reach from the back to the edges of the belly. Accordingly, Linnaeus enumerates the single-banded, the three-banded, the four, six, seven, and nine-banded *dastyus*. See farther under **ARMADILLO** and **TATU**.

DASTYS, *darsis*, *darsis*, thick, close, tough, in Prothet. and Corp. is an epithet for a tongue condensed, contracted, and exasperated with heat and darsis, as it happens in phrenitis. *James's Med. Dic.*

DATA, in *Mathematics*, certain things, or quantities, supposed to be given; or known, in order, from them, to find out other things or quantities, which are unknown, or sought for. A problem, or question, generally consists of two parts: *data* and *quæritur*.

Euclid has an express treatise of *data*, wherein he uses the word for such spaces, lines, and angles, as are given in magnitude; or to which we can assign others equal.

From the primary use of the word *data* in mathematics, it has been transferred into other arts, as philosophy, medicine, &c. where it expresses any quantity, which, for the sake of a present calculation, is taken for granted to be fact, without requiring an immediate proof for its certainty; called also the given quantity, number, or power. And hence also such things as are known, from whence either in natural philosophy, the animal mechanism, or the operation of medicines, we come to the knowledge of others unknown, are now frequently, in physical writers called *data*.

DATE, an addition, or appendage, in writings, *data*, instruments, letters, the expending the day, and month of the year, when the act, or letter, was passed or signed; together with the place where the time was done.

The word is formed from the Latin *datum*, *gratu*, the participle

fied with Guy, son of Guy the Fat, calls the latter simply Guy the Old, and the former always count *Dauphin*. and adds, that no record nor monument ever attributes the title of *dauphin* to Guy the Fat, or any of his predecessors: so that it must necessarily have taken its rise in his son, all whose successors so constantly assumed it, that it became the proper name of the family. He died in 1142, in the flower of his youth; so that it must be about the year 1120, that the title commenced; and without doubt, adds he, on some illustrious occasion. He observes farther, that this prince was of a military disposition, and delighted in nothing but war; and again, that it was the custom of the cavaliers to deck their calks, coats of arms, and the housings of their horses, with some figure, or device, peculiar to themselves, whereby they were distinguished from all others engaged in the same combat or tournament. From all these circumstances he conjectures, that this Guy chose the *dauphin* for his signature; that this was the crest of his helmet; and that he bore it on his coat in some notable tournament, or battle, wherein he distinguished himself. And this, Chotier makes no doubt, is the real origin of the appellation. Nothing was more common, in those times, than to make proper names become the names of families, or dignities. Witness the Adenars, Artlands, Aynards, Atelemans, Berengiers, and infinite others, who all owe their names to some one of their ancestors, from whom it has been transmitted throughout the family.

The seignours, or lords, of Auvergne, have likewise borne the appellation of *dauphin*: but the *dauphin* of Auvergne had it not till a good while after those of the Viennois, and even received it from them. The manner was this: Guy VIII. *dauphin* of Viennois, had by his wife Margaret, daughter of Stephen, earl of Burgundy, a son and two daughters. The son was Guy IX. his successor. Beatrix, one of the daughters, was married to the count d'Auvergne, who, according to Blondel, was William V. or rather, as Chotier and others hold, Robert VI. father of William V. This prince lost the greatest part of the county Auvergne, which was taken from him by his uncle William, assisted by Louis the Young; and was only left master of the little canton whereof Vodable is the capital. He had a son whom he called *Dauphin*, on account of Guy, or Guigues, his uncle by the mother's side. From his time his successors, holding the same petty canton of Auvergne, styled themselves *dauphins* of Auvergne, and bore a *dauphin* for their arms.

DAUPHIN, in *Cynology*, the name of a species of shell-fish. It is one of the round-mouthed *Isopods*, or *calappa lunares*, and is ornamented with rows of indented eminences, on all the turns of the shell.

DAUPHINS, or **DELPHINS**, in *Literary History*, a name given to the commentators on the ancient Latin authors, who were employed by order of Louis XIV. of France, for the benefit of the prince, under the care and direction of M. de Montausier his governor, Bossuet and Huët his preceptors. They were thirty-nine in number.

DAWEL, *cardell*, in the language of the Ceylonese, drum-cinnamon. This is called in Low Dutch, *trammel cardell*. The reason of the name is, that the wood of the tree which affords this species, when dried, is light and tough, and is used to make drums of. The bark is taken off while the tree is growing, and is of a pale colour. It is a very bad kind of cinnamon, and is very rarely sold as such; but the natives use it in medicine.

DAY, a division of time, deduced from the appearance and disappearance of the sun.

The *day* is of two kinds; *artificial*, and *natural*. **DAY**, *artificial*, which seems to be that primarily meant by the word *day*, is the time of light; determined by the sun's rising and setting.

This is properly defined, the stay of the sun above the horizon: in opposition to which, the time of darkness, or the sun's stay below the horizon, from setting to rising again, is called *night*.

DAY, *natural*, is the space of time wherein the sun performs one revolution round the earth; or, more fully, the time wherein the earth makes a rotation on its axis; which the Greeks more properly express by *noctambon*, *noctambon*, q. d. *night-day*. This is either *astronomical* or *civil*. The *astronomical day* begins at noon, when the sun's centre is on the meridian, and is reckoned twenty-four hours to the following noon.

The epocha, or beginning of the *civil day*, is the term from which one *day* begins, and in which the preceding *day* concludes. The fixing of this term is of some importance. It is certain, that, for the more commodious distinguishing of *days*, it ought to be fixed in some moment of time wherein the sun is in some distinguishable part of the heavens. The most eligible, therefore, should

be the moments wherein the sun passes either the horizon, or the meridian. In effect, as there is no moment can be more accurately determined by observation, than that in which the sun passes through the upper meridian; if regard be had to the exactness of the measure, the noon-tide has the best pretensions; the rising and setting of the sun being disturbed by the refractions; beside that, the horizon is seldom clear of clouds. But yet, as the *artificial day* does begin with the sun's rise, and ends with the setting; and, besides, the sun's passing the horizon is a thing easily observed; the rising or setting of the sun should appear the most commodious, though not most accurate, epoch or beginning of the *civil day*. As, then, there are not wanting reasons for beginning the *natural day*, both from the sun's passing the meridian, and the eastern and western side of the horizon, it is no wonder, that different nations should begin their *day* differently.

Accordingly, 1st, The ancient Babylonians, Persians, Syrians, and most other eastern nations, with the present inhabitants of the Balearic islands, the Greeks, &c. being their *day* with the sun's rising. 2^{dly}, The ancient Athenians and Jews, with the Austrians, Bohemians, Marcomani, Silones, modern Italians, and Chinese, reckon it from the sun's setting. 3^{dly}, The ancient Umbri and Arabians, with the modern astronomers, at noon. And, 4^{thly}, The Egyptians and Romans, with the modern English, French, Dutch, Germans, Spaniards, and Portuguese, at midnight.

The *day* is divided into hours; and the week, month, &c. into *days*. For the origin of the English names of the *days* of the week, see **WEEK**.

As to the different length of the *day* in different climates, it has been a matter of some controversy among astronomers, whether or no the *natural day* be all equally long throughout the year; and, if not, what is their difference? A professor of mathematics at Seville, in a memoir in the Philosophical Transactions, asserts, from a continued series of observations for three years, that they are all equal. Mr. Flamsteed, in the same Transactions, refutes the opinion; and shews, that one *day*, when the sun is in the equinoctial, is shorter than when he is in the tropics, by forty seconds; and that fourteen tropical *days* are longer than to many equinoctial ones, by one sixth of an hour, or ten minutes. This inequality of the *days* flows from two different principles: the one, the eccentricity of the earth's orbit; the other, the obliquity of the ecliptic with regard to the equator, which is the measure of time. As these two causes happen to be combined, the length of the *day* is varied. See **EQUATION of time**.

DAY, in *Law*, is frequently used for the *day* of appearance in court, either originally, or upon application.

We say, He had a *day* by the rolls; i. e. he had a *day* of appearance assigned him.

If a fact be done in the night, you must say in law proceedings, *in nocte quidem acti*.

There are several return *days* in the terms; and if either of them happen upon a Sunday, the *day* following is taken instead of it; for Sunday is *die non juridica*; and so is Ascension day in Easter term, St. John the Baptist in Trinity term, All Saints and All Souls in Michaelmas term, and the Purification of the Virgin Mary in Hilary term. 2 Inst. 264.

DAY-COAL, in *Natural History*, a name given by the miners of England, and the common people who live in coal countries, to that seam or stratum of the coal which lies uppermost in the earth. The same vein or stratum of coal usually runs a great way through the country, and dips and rises in the earth in different places; so that this upper stratum, or *day-coal*, is in the various parts of the same stratum, sometimes near the surface, and sometimes at many fathoms deep. The subterranean fires found in some of our coal countries principally feed on this coal, and are nearer, or farther from the surface, as it rises or sinks. Phil. Trans. N° 130.

DAY-LIGHT, in *Law*. In respect to *day-light*, before sun-rising, and after sun-setting, is accounted part of the *day* by common law; as to robberies committed in the *day-time*, when the hundred is liable. 7 Rep. 6.

The law regularly rejects all fractions and divisions of a *day* for the uncertainty. 5 Rep. 1. 1 Inst. 135.

DAY-LIT, in *Botany*. See **LIT**.

DAY'S WORK, in *Sea Language*, denotes the reckoning or account of the ship's course, during twenty-four hours, or between noon and noon, according to the rules of trigonometry. See **DEAD-RECKONING**.

DAY'S HAND, are *days* set down by statute, or order of the court, when writ shall be returned, or when the party shall appear on the writ served.

To be dissatisfied without *day*, *sine die*, is to be finally discharged the court.

DAYS of precision, in the *Exchequer*. See *REMBURANCE*.
DAYS of grace, in *Commerce*, are a number of days allowed by custom for the payment of a bill of exchange, after the same becomes due; i. e. after the time it was accepted for is expired.

In England, three *days of grace* are allowed: so that a bill accepted, in order to be paid, e. g. ten days after sight, is not to be paid till thirteen days. Throughout France, they allow ten *days of grace*; as many at Dantz; eight at Naples; six at Venice, Amsterdam, Rotterdam, and Antwerp; four at Francfort; five at Leipzig; twelve at Hamburg; six in Portugal; fourteen in Spain; thirty in Genoa, &c. Note, Sundays and holidays are included in the number of *days of grace*.

DAYS-man is used in some parts of England for an arbitrator or judge: and it has been observed that the word *day* signifies judgment.

DAYS, Plur. See *ABSTINENCE*.

DAYS, Day. See *ANNUAL*. See *CANONICAL*.

DAYS, Critical, Dis-critical. See *CRITICAL days*.

DAYS, Intercalary. See *INTERCALARY days*.

D'AYENA, in *Botany*, *moist*. Its characters are these: the flowers arise from the wings of the stalk; they have a five-lobed empanment, and five heart-shaped petals; it hath five stamens inserted in a short nectarium; and a five-cornered germen, situated at the bottom of the nectarium, which afterward becomes a roundish five-cornered capsule having five cells, each having one kidney-shaped seed. There is but one species known, a native of Peru; which is named from M. Le Duc D'AYENA, a great lover of botany, and who has a noble garden at St. Germain.

DAZE, in *Natural History*, a name given by our miners to a sort of glittering stone, which often occurs in their works; and, as it is an unprofitable substance, is one of those things which they call weeds. The word *daze* takes in, with them, every stone that is hard and glittering; and therefore it comprehends the whole genus of the *telusgia*, or stony nodules, which have flakes of talc in their substance: these, according to the colour of the stony matter they are bedded in, and their own colour, give the names of *black daze*, *white*, *red*, and *yellow daze* to these stones.

These *dazes* are generally of the poorer part of the vein. The thoud-stones are many of them of this nature, and the ends of the veins degenerate again into them. Phil. Trans. N° 60.

DEACON, *Diáconus*, a person in the lowest degree of holy orders, whose business is to baptize, read in the church, and assist at the celebration of the eucharist.

The word is formed from the Latin *diáconus*; of the Greek *diákonos*, minister, servant.

Deacons were first instituted, seven in number, by the apostles, Acts, chap. vi. which number was retained a long time in several churches. Grotius apprehends that the order of *deacons* in the Christian church corresponded to that of *shofranim* in the Jewish synagogue. Their office was, to serve in the *agape*, and to distribute the bread and wine to the communicants, and dispense the alms. Tertullian informs us, that the deacons preached, and, in the absence of the bishop and presbyters, conferred the sacrament of baptism. De Bapt. p. 602.

By the ancient canons, marriage was not incompatible with the state and ministry of a *deacon*; but it is now a long time that the Romish church has prohibited their marrying; and the pope only grants them dispensations for very important causes; and, after this dispensation, they lose the rank and functions of their order, and return to a lay state.

At Rome, under pope Sylvester, they had only one *deacon*; then seven were appointed; then fourteen; and, at last, eighteen; who were called *cardinal deacons*, to distinguish them from those of other churches.

Their office was, to take care of the temporalities of the church, to look to the rents and charities, and provide for the necessities of the ecclesiastical, and even of the pope. The collecting of the rents, alms, &c. belonged to the *subdeacons*; the *deacons* were the depositaries and distributors. Having thus the management of the revenues of the church in their hands, their authority grew apace, as the riches of the church increased. Those of Rome, as being ministers of the first church, preceded all others, and even at length took place of the priests themselves. Doubtless, it was the avarice of the priests that made them give place to the *deacons*, who had the disposal of the money.

The *deacons* rehearsed certain prayers at the holy office, which were thence denominated *diacinal*.

They took care that the people at church behaved themselves with due modesty and respect. They were not allowed to teach publicly; at least not in the presence of a bishop or priest. They only instructed the catechumens, and prepared them for baptism. The doors

of the church were likewise in their custody; though, in after-times, that charge was committed to the *subdeacons*.

The office of a *deacon*, in the church of England, according to the form of ordination, is to baptize, preach, and assist in the administration of the Lord's supper; and, in short, to perform all the other offices in the liturgy, which a priest can do, except that of consecrating the elements of the Lord's supper, and pronouncing the absolution. No person can be ordained a *deacon* under the age of twenty-three years, unless by a faculty or dispensation obtained from the archbishop of Canterbury; and in order to this, he must be provided with a title to a cure, or be a fellow or chaplain in some college in Cambridge or Oxford, or a matter of arts of five years standing, living at his own charge in either of the universities, or be admitted by the bishop who ordains him to some benefice or curacy then void. Otherwise the ordaining bishop shall maintain him, till he is preferred to some ecclesiastical living. And by stat. 13 and 14 Car. II. c. 4. no person is capable of being admitted to any benefice or ecclesiastical promotion, till he be ordained a priest; nor is a *deacon* capable of a *DONATIVE*, but is only allowed to use his orders as a chaplain to some family, a curate to some parish, or a lecturer under a title.

DEACONESS, *Diáconissa*, an office in use in the primitive church, though now laid aside. St. Paul makes mention thereof in his Epistle to the Romans; and the younger Pliny, in a letter to Trajan, tells that prince, that he had ordered two *deaconesses*, whom he calls *ministrae*, to be tutored.

Deaconess was a title given to certain devout women, who consecrated themselves to the service of the church, and rendered those offices to the women, which men could not decently do: as in baptism, for instance, which was conferred, by immersion, on women as well as men.

They were likewise to look to the doots on the side the women were on, who were separated from the men, according to the custom of those times. They had the care and inspection of the poor, sick, &c. And in times of persecution, when a *deacon* could not be sent to the women, to exhort and fortify them, a *deaconess* was sent. See Balsamon on the eleventh canon of the council of Laodicea; and the Apostolical Constitutions, lib. ii. cap. 57. To say nothing of the epistle of Ignatius to the people of Antioch; where, what is said of *deaconess*, is supposed to be an interpolation.

The council of Nice ranks *deaconesses* among the clergy; though some hold, that their ordination was not sacramental, but a more ecclesiastical ceremony. However, it gave them a pre-eminence above the rest of their sex; for which reason the council of Laodicea forbade the ordaining of any more for the future. The office of *deaconess* expired in the Western church about the twelfth century, and in the Eastern about the thirteenth.

Atto of Vercell, in his eighth letter, gives the reason of their being abolished: he observes, that in the first ages the ministry of women was necessary, in order to the more easy instructing of other women, and recovering them from paganism; and that they likewise served for the more decent administration of baptism to the same: but that it was not then necessary, because none but children were baptized; and it might now be added, because baptism is only conferred by sprinkling.

The number of *deaconesses* does not seem to have been fixed: the emperor Heraclius, in his letter to Sergius, patriarch of Constantinople, orders that in the great church of Constantinople there be forty *deaconesses*; whereas there were only six in that of the Mother of God, in the quarter of the Blachernæ.

DEACONRY, *Diáconia*, the order or ministry of a *deacon*, or *deaconess*. See *DEACON*, and *DEACONESS*.

DEACONRY, *Diáconia*, is also a name still reserved to the chapels and oratories in Rome, under the direction of the several deacons, in their respective regions or quarters.

To the *deaconries* were annexed a sort of hospitals, or boards, for the distribution of alms, governed by the regular deacons, called cardinal deacons, of whom there were seven, answering to the seven regions, their chief being called the arch-deacon.

The hospital adjoining to the church of the *deaconry*, had an administrator for the temporal concerns, called the *father of the deaconry*, who was sometimes a priest, and sometimes a layman.

At present there are fourteen of these *deaconries* or hospitals at Rome, which are reserved to the cardinals. Du-Cange gives us their names: as the *deaconry* of St. Maria in the Broad-way, the *deaconry* of St. Eustachio near the Pantheon, &c.

tion: she had a sister, with whom she had practised her language more than with any body else; and in the night, by laying her hand on her sister's mouth, she could perceive by that what she said, and could discourse with her in the dark. *Harm. Let. iv. p. 248.*

It is observable that *deaf* persons, and several others thick of hearing, hear better and more easily, if a loud noise be raised at the time when you speak to them; which is owing, no doubt, to the greater tension of the ear-drum, on that occasion. Dr. Willis mentions a *deaf* woman, who, if a drum were beat in the room, could hear any thing very clearly; so that her husband hired a drummer for a servant, that by his means he might hold conversation with his wife. The same author mentions another, who, living near a temple, could always hear very well, if there was a ringing of three or four bells; but never else.

Dr. Buchner relates an extraordinary method of making *deaf* persons to hear, by applying thin slips of wood, about six feet long, an inch broad, and as thick as the back of a knife, at one end to the upper teeth of the speaker, and at the other to the upper teeth of the *deaf* person. Many trials were made to ascertain the fact, and the voice was found perceptible and distinct. This method, he observes, may be adapted to all persons afflicted with *deafness*, provided the auditory nerves are not injured or destroyed at their origin. See Buchner's Easy and practicable Method to enable *deaf* Persons to hear, translated from the German, 1770.

DEAL, a well-known kind of wood, of great use.

A very good method of seasoning planks of *deal* and fir, is to throw them into salt-water as soon as they are felled, and keep them there three or four days, frequently turning them. In this case they will be rendered much harder, by drying afterwards in the air and sun; but neither this nor any other means yet known, will preserve them from shrinking.

Deals called *Bulgundory deals*, the hundred containing six fives, pay on importation 3*l.* 8*s.* 9*d.* and drawback 3*l.* 2*s.* the rate 1*st.* *Measero deals*, six fives, pay 3*l.* 2*s.* 10*d.* and drawback 1*l.* 1*s.* the rate 4*th.* *Norway deals*, six fives, pay 1*l.* 8*s.* 7*d.* and drawback 1*l.* 6*s.* 3*d.* the rate 5*th.* *Spruce deals*, six fives, pay 4*s.* 6*d.* and drawback 3*l.* 18*s.* 9*d.* the rate 15*th.* *Deals* from Russia, and all other countries not particularly rated, exceeding twenty feet in length, pay 4*s.* 5*d.* and drawback 1*l.* 18*s.* 9*d.* the rate 15*th.* *Deals* from Sweden or any other country, of twenty feet in length or under, not otherwise rated, the hundred, and twenty, pay 1*l.* 8*s.* 7*d.* and drawback 1*l.* 6*s.* 3*d.* the rate 5*th.*

Rods of *deal* expand laterally, or cross the grain, in moist weather, and contract again in dry; and thence have been found to make an useful hygrometer. Phil. Trans. N^o 428. p. 124. See *HYGROMETER*.

DEAN, a prime dignity in most cathedral and collegiate churches; being usually the president of the chapter. He is called *dean*, *diaconi*, of the Greek *dean*, *ten*, as being supposed to preside over ten canons or prebendaries, at least.

Canonists distinguish between *deans* of cathedral, and those of collegiate churches. The first, with their chapter, are regularly subject to the jurisdiction of the bishop. As to *deans* of collegiate churches, they have usually the contentious jurisdiction in themselves, that is, they exercise jurisdiction over their canons in all civil or criminal matters; though sometimes this belongs to them in common with the chapter.

In England, as there are two foundations of cathedral and collegiate churches, the old and the new (the latter being those founded by Henry the Eighth, on the suppression of the abbots and priors, when their convents were turned into *dean* and chapter) so there are two ways of creating the *dean*. Those of the old foundation, as the *dean* of St. Paul's, York, &c. are raised to their dignity much like a bishop; the prince first sending out his commissioner to the chapter; the chapter then choosing the king yielding full royal assent, and the bishop confirming him, and giving his mandate to install him. Those of the new foundation, as the *deans* of Canterbury, Durham, Ely, Norwich, Winchester, &c. are elective, and are installed by a theocratic court; only by the king's letters patent, without either election or confirmation. There are some cathedral churches, which never had a *dean* as that of St. David and Landaff, where the bishop is the head of the chapter, and in his absence the archdeacon.

Constitutions, we are told, erected an office of nine hundred and fifty persons at Constantinople, taken out of divers trades and professions, whom he exempted from all impositions, and bestowed them on the cathedral church, to render the offices of burial *gratis* to the je-

funct, particularly to the poor. These he called *diaconi*, and *diaconii*, probably because they were divided by tens; each whereof had a *bier*, or *litter*, to carry the bodies in. It is supposed to be their, who, under Constantine, began to be called *capituli*; i. e. clerks destined for labour; for they are usually ranked among the clerks, and even before the chantors. By a law of the year 357, it appears, that there were some of these *capituli* at Rome.

DEAN is also a title applied among us to divers persons that are the chief of some peculiar churches, or chapels: as, the *dean* of the King's chapel, who has no jurisdiction; of the ARCHBISHOP of Basel, founded by William I. who had jurisdiction within the liberty of Basel, is presentable by the duke of Montagu, and instituted and inducted by the bishop of Chichester, but not subject to his visitation; of Bocking, who hath a court and jurisdiction to hold plea of all ecclesiastical matters arising in several parishes within his peculiar, and is constituted by commission from the archbishop of Canterbury, like the *dean* of Arches. There are also *dean* *dean*, and *dean* *dean*, who cannot confirm any grants, &c.

DEAN, *Karl*, or *Ueber DEAN*, was formerly an ecclesiastical person, who had a district of ten churches, or parishes, either in the country or city, within which he exercised jurisdiction. These *rural deans* were sometimes called *groupenherren*; and at first they were, both in order and authority, above the archdeacons. They were at first elected by the clergy, and by their votes deposited; but afterwards they were appointed, and removed, at the discretion of the bishop; and hence they were called *dean* *dean*, to distinguish them from the *archdeacon* *dean*, who were called *dean* *dean*. They seem to have been deputies of the bishop, and as such found his diocese, the better to inspect the conduct of the parochial clergy, and therefore armed with an inferior degree of judicial and coercive authority.

We meet with *rural deans* as early as the sixth century. Hincmar, in a capitular to his archdeacons, reserves the right of electing them to himself; and only allows it to the archdeacons, in case he be absent, and by provision only. Some take the *rural dean* to hold the rank and place of the *archbishop*. Be this as it will, it is certain, they are very ancient in France, Germany, and England; though, till the end of the sixteenth century, they were unknown in Italy; because the bishoprics being there exceedingly small, they were not needed. St. Charles Borromeo is said to have first introduced them there. Their office is now wholly extinguished in England, the authority which they had being executed by the archdeacons and chancellors of bishoprics.

DEAN, in the ancient monasteries, was a superior established under the abbot, to ease him in taking care of ten monks; whence he was called *dean*, in imitation of those officers called by the same name among the Romans, who had ten soldiers under them.

These *monasteries* being now left populous that they were in ancient times, the abbot, or prior, does not stand in so much need of being aided; so that these *deans* are, in general, set aside.

DEAN and Chapter. Anciently, bishops did not ordinarily transact matters of moment *fine* *capitulum* *principatum*, who were then called *sancti* *capitulum* and colleagues of the bishops; represented, in some measure, by our chapters of cathedrals, wherein the *dean* and some of the prebends are, upon the bishop's summons, to assist him in ordinations, depositions, condemnations, excommunications, and other weighty concerns of the church. See CHAPTER.

DEAR *DEAR*, in *dear*. See DEAR *DEAR*. **DEATH**, *dean*, is generally considered as the separation of the soul from the body; in which sense it stands opposed to life, which could in the union thereof.

Physicians have usually defined *death* by a total stoppage of the circulation of the blood; and a cessation of the animal and vital functions consequent thereon; as expiration, sensation, &c.

An animal body, by the actions inseparable from life, undergoes a continual change in time, its smallest fibres become rigid; its minute vessels grow into solid fibres no longer pervious to the fluids; its greater vessels grow hard and narrow; and every thing becomes contracted, closed, and bound up; whence the organs, immobility, and extension, observed in old age. By such means, the offices of the minister vessels are destroyed, and the humours stagnate, harden, and at length coalesce with the solids: thus are the subtiler fluids in the body intercepted and lost, the concoction weakened, and the separation prevented; only the coarser juices continue to run slowly through the greater vessels, to the preservation of life, after many of the animal functions are destroyed. At length, in the process of these changes, *death*

death itself becomes inevitable, as the necessary consequence of life.

But it is rare, that life is thus long protracted, or that death succeeds merely from the decays and impairments of old age; difficulties, in a long and hoarse train, usually precipitate dissolution.

It is generally taught, that the life of those animals, which we call perfect, consists in a continued flux and reflux of blood, nervous juice, and air, to and from the principal organs; and that a man may be reckoned dead when he no longer breathes, and his heart and arteries have left off all circulation and pulsation. Even Lancisi, the best author on this subject, says, that without a small degree of respiration, and some little motion and trembling of the heart, there is no life. In consequence of this system, the general practice is, that as soon as these symptoms of life are gone, all hopes and endeavours to maintain the small remains of life are laid aside. But Dr. Stenon does not admit this doctrine, being of opinion, that after the motion of the heart, arteries, and lungs ceases, there often remains a small degree of vital principle, deserving attention. After a full stop of all those organic motions on which life is said to depend, the juices frequently retain so much of the animal process, as frequently serves to keep up warmth for a long time; which, with proper cherishing, might perhaps restore life entirely. Every age and country affords instances of surprising recoveries after lying long for dead. From the number of those preserved by lucky accidents, we may conclude a far greater number might have been preserved by timely pains and skill. Med. Ed. Edinb. vol. v. art. 77.

This ingenious author hopes, from his theory, that one, who from all the above mentioned motions ceasing, may with propriety be called dead, may recover, and be properly said to come to life again.

His theory is, that the cause of animal heat, or of the finest motion which had been going on vigorously, while the progressive motion of the fluids in the vessels continued, is now checked; yet still proceeds in a lower manner, perhaps like the beginning of fermentation or putrefaction. By this degree of the animal process, the mass of fluids, particularly in the great reservoir of venous blood, the heart, rarefying, pressing every way, and being resisted by the valves, swells so as to fill the flaccid right auricle of the heart, which had been some time empty; and thus stimulating its fibres, which were at rest, puts them into motion again; as we see the heart, after being taken out of the body, by being pricked, or having warm water thrown on it, beat itself, though it has been for some time motionless. The right auricle being thus filled, and stimulated into a contraction, fills the ventricle; which, being trimmed, likewise contracts and empties itself into the pulmonary artery; whereby the circulation begins where it left off, and life is restored, if the organs and juices are in a fit disposition for it, as they perhaps are much oftener than is imagined.

From hence it seems, that death does not inevitably attend an entire organic rest of what we call the fluids of the body; nay, that one cannot be called dead till the energy of the blood is so far gone, that, though assisted by all possible means, it can never be again able to fill, and stimulate into contraction, the right *sinus venosus* and auricle of the heart.

See a remarkable case, in support of this opinion, in Med. Ed. Edinb. vol. v. art. 55. See BROWNING.

The learned Winslow has given us a treatise upon the uncertainty of the signs of death.

The law distinguishes between natural and civil death: the former is the actual termination of life; the latter, when a person is not actually dead, but adjudged to be by law. Thus, if a person for whose life an estate is granted remains beyond sea, or is otherwise absent seven years, and no proof be made of his being alive, or becomes a professed monk, he shall be accounted naturally dead. However, the latter disability, since the Reformation, is held to be abolished.

DEATH, *apud os*. See APPEAL.

DEATH-WATCH, in Zoology, the English name of the *pediculus* of old wood, a species of the *torus*, belonging to the order of *apera*, and class of insects in the Linnean system. It is nearly of the size of the common louse; and the noise, resembling the beating of a watch, is made by the male or female, when wooing each other. This ticking noise the populace have long taken for a presage of death, in the family where it is heard; whence it is also called *pediculus fatalis*, *mortuus*, *pulsatorius*, &c.

There are two kinds of death-watches: of the first we have a good account in the Philosophical Transactions, by Mr. Allen. It is a small beetle, five sixteenths of an

inch long, of a dark brown colour, spotted; having pellucid wings under the raying, a large eye, or helmet, on the head, and two antennae proceeding from beneath the eyes. The part with which it beats, he observed, was the extreme edge of the face, which he chooses to call the upper lip; the mouth being protruded by this bony part, and lying underneath, out of view. In figure, as it appears in a microscope, see represented in *Tab. Nat. Hist. fig. 2*.

This account is confirmed by Dr. Derham, with this difference, that, instead of ticking with the upper lip, he observed the insect to draw back its mouth, and beat with its forehead. The author had two death-watches, a male and female, which he kept alive in a box, several months; and could bring one of them to beat whenever he pleased, by imitating its beating: and by this ticking noise he could frequently invite the male to get up upon the other, in the way of coition. When the male found he got up in vain, he would get off again, beat very eagerly, and then up again: whence the ingenious author concludes those pulsations to be the way whereby those insects woo one another, and find out, and invite each other to copulation.

The second kind of death-watch is an insect in appearance quite different from the first. The former only beats seven or eight strokes at a time, and quicker; the latter will beat some hours together, without intermission; and his strokes are more leisurely, and like the beat of a watch. This latter is a small greyish insect, much like a louse when viewed with the naked eye. Its figure, as magnified, is seen in *Tab. Nat. Hist. fig. 1*. The ticking, as in the other, is a wooing act.

This insect is at first a minute white egg, much smaller than the nuts of lice; though the insect is near as big as a louse. In March it is hatched, and creeps about with its shell on. When it first leaves its shell it is even smaller than its egg; though that he scarce discernible without a microscope. In this state it is somewhat like the mites in cheese: from this small state they grow gradually to their mature or perfect state; when they become like the old one, they at first run about much more swiftly than before. Phil. Trans. abr. vol. v. p. 26, &c.

DE BENE ESS, a Latin phrase used in our law-books.

To take, or do, a thing *de bene esse*, is to accept, or allow it as well done for the present; but when it comes to be more fully examined, or tried, to stand or fall, to be allowed or disallowed, according to the merit, or well-being, of the thing in its own nature; or, as we say, *Valuit quantum valere possit*.

Thus, in chancery, upon motion to have one of the *less* principal defendants in a cause examined as a witness, the court (not then thoroughly examining the justness of it, or not hearing what may be objected on the other side) often orders such a defendant to be examined *de bene esse*, i. e. that his depositions shall be allowed, or suppressed, at the hearing of the cause upon a full debate of the matter, as the court shall think fit; but for the present they have a well-being, or conditional allowance. Thus also in common law, the judges often take bail *de bene esse*, to be allowed or rejected upon the approbation or exception of the plaintiff's attorney.

DEBENTURE, a kind of writing in the nature of a bond, first given in 1659, to charge the commonwealth to secure the soldier-creditor, or his assign, the sum due, upon auditing the accounts of his arrears.

The word is now also used in the exchequer, and in the king's household, where debentures are usually given to the servants for the payment of their wages, board-wages, and the like.

Debenture is mentioned in the act of oblivion, 12 Car. II. cap. 2. and since the late Revolution, has been used in many acts of parliament, especially in that which relates to the forfeited estates in Ireland, out of which the soldiers debentures are appointed to be satisfied. 11 W. III.

DEBENTURES, in Commerce, a term used at the custom-house, where the exporter of any merchandise is entitled to any bounty or drawback, by act of parliament, on the exportation; in which case this debenture is a peculiar certificate signed by the officers of the customs, which entitles the trader to the receipt of such bounty or drawback. All merchandise that are designed to be taken on board for that voyage, being entered and shipped, and the ship being regularly cleared out, and sailed out of port on her intended voyage, debentures may be made out from the exporter's entries, in order to obtain the drawbacks, allowances, bounties, or premiums; which debentures for foreign goods are to be paid within one month after demand; and in making out these debentures, it must be observed, that every piece of vellum, parchment, or paper, containing any debenture for drawing back customs

or duties, must, before writing, be stamped, and pay a duty of eight pence.

The form of *debtures* vary, according to the merchandise exported. In the execution of *debtures* for tobacco, it must be particularly observed, 1. that *debtures* for the same quantity may be made in one or more parcels; 2. that the exporter's oath must be printed, specifying whether he ads for himself, or by commission; 3. if exported to any other foreign ports than those of Ireland, the word Ireland must be added to the oath after Great Britain; 4. that as no tobacco may be consumed in ships of war in Europe, but what has paid full duties, and been manufactured in Great Britain, no drawback is to be allowed for any tobacco exported in men of war; 5. that eight pounds of tobacco per hoghead of 350 pounds or more, allowed for freight at importation, must not be deducted on exportation; 6. that *debtures* for tobacco exported to Ireland, must not be paid till a certificate be produced, testifying the landing thereof; 7. that no persons may swear to the exportation, but such as are permitted to swear to *debtures* for other goods. In *debtures* for all other foreign goods, no person may be admitted to swear to the exportation, but the true exporter, either as a proprietor, or who being employed by commission, is concerned in the direction of the voyage. All kinds of *debtures*, before delivered or paid to the exporters, are entered into a separate book kept for that purpose by the collector or controller of the customs. See *BOUNDS*.

DEBET, among *Merchants*, signifies the sums due to them for goods sold on credit, for which they have charged their journal or ledger. It is more particularly understood of the remainder of debts, part of which has been paid on account.

DEBIT, among *Book-keepers*, is used to express the left-hand page of the ledger, to which are carried all articles supplied or paid, on the subject of an account.

DEBIT & DEBITUM, in *Law*, are Latin words used in the bringing writs and actions; and an action shall always be in the *debit & detinet*, when he who makes a bargain or contract, or lends money to another, or he to whom a bond is made, bringeth the action against him who is bounden, or party to the contract and bargain, or unto the lending the money, &c. But if a man sells to another a horse, &c. if he brings debt for the horse, the writ must be in the *detinet* only. New. Nat. Br. 265.

DEBIT & SOLET, are also formal words made use of in writs, and some writs have these words in them, which ought not to be omitted. Likewise, according to the diversity of the case, both *debit & solut* are used, or *debit* alone: as a *quid permuta* may be in the *debit & solut*, or in the *debit* only, as the demandant claims. And if a person sues to recover any right, whereof his ancestor was dispossessed, by the tenant or his ancestor, then he useth the word *debit* alone in his writ, because his ancestor only was dispossessed, and the estate discontinued: but if he sue for any thing that is now first of all denied him, then he useth *debit & solut*, because his ancestor before him and he himself usually enjoyed the thing sued for, until the present refusal of the tenant. Reg. Orig. 140. The writ of *facta melandina* is a writ of right in the *debit & solut*, &c. F. N. B. 98.

DEBILITY, in a *Medicinal Sense*, is a relaxation of the solids, which often induces weakness and fainting.

DEBRUIZED, or **DEBRUISED**, in *Heraldry*, is when we would intimate the grievous restraint of any animal, which is sharr'd its natural freedom by any of the ordinaries being laid over it.

Thus when a pale, &c. is borne upon a beast in an escutcheon, the beast is said to be *debruis'd* by the pale.

DEBT, a thing due to another, whether it consist of money, goods, or services.

The legal acceptance of debt is a sum of money due by certain and express agreement: as, by a bond for a determinate sum; a bill or note; a special bargain; or a rent reserved on a lease, that is fixed and unalterable. The non-payment of these is an injury, for which the proper remedy is by action of debt, to compel the performance of the contract, and recover the specific sum that is due. Actions of debt are now seldom brought but upon special contracts under seal, in which the sum due is clearly and precisely expressed. The form of the writ of debt is sometimes in the *debit & detinet*, and sometimes in the *detinet* only.

By our law, debts due to the king are to be satisfied in the first place in all sales of executethip, and administration; and till the king's debt be satisfied, he may protect the debtor from the arrest of any other creditor. At the common law, debt lies not for rent upon a lease for life, though it does on a lease for years; but the remedy is assize, if the plaintiff have seisin, or by distress.

3 Rep. 65. But by stat. 8 Anne, cap. 17, any person having rent in arrear, upon any lease for life or lives, may bring action of debt for such rent, as where rent is due on a lease for years. Action of debt will lie against a lessee, for rent due after the assignment of the lease; for the personal privity of contract remains, notwithstanding the privity of estate is gone. 3 Rep. 22. But after the death of the lessee, it is then a real contract, and runs with the land. Cro. Eliz. 555.

We meet with divers kinds of debts: *active debts*, are those whereof a person is creditor; *passive debts*, those whereof he is debtor. There are also *real debts*, *personal debts*, and *mixed debts*. See *RECORD*, *SUMPLET*, and *SPECIALTY*.

It behoves an executor or administrator to pay regard to the priority of debts in discharging them; otherwise, on deficiency of assets, he must answer those of a higher nature out of his own estate: such are funeral charges, and expence of proving the will; debts to the king on record or specialty; debts, which by particular statutes are to be preferred to all others, as forfeiture for not burying in woollen, money due on poor's rates, letters to the post-office, and some others; debts of record, as judgments, statutes, and recognizances; debts due on special contracts, as for rent, on bonds, covenants, &c. under seal, and lastly, debts on simple contracts, as notes and verbal promises, and servants wages.

DEBT, Chirographary, in the *French Law*, is that due by virtue of a note, or writing under one's hand, and not proved in judicature.

DEBT, Hypothecary, is that due in virtue of some contract, or judgment.

DEBT, Prædatory, is that arising from an alienation of lands, &c. the whole purchase whereof has not been paid. **DEBT, Privileged**, is that which must be satisfied before all others; as, the king's tax, &c.

DEBT, National. See *FUGIO*.

DEBTOR, a person who owes to another. If a person debtor to another makes his creditor or detest his executor, or if such creditor obtain letters of administration to his debtor, he may retain sufficient to pay himself before any other creditors whose debts are of equal degree. Blackst. Com. vol. iii. p. 18.

DEBTOR, a person who owes something to another; in opposition to creditor, which is he to whom it is owing.

DECACHORDON, in *Antiquity*, a musical instrument of ten strings, called by the Hebrews *harp*, resembling our harp, of a triangular figure, with a hollow belly, and sounding from the lower part.

DECACTIS, in *Natural History*, a name given by some to a kind of star-fish of the branched, or astrophyle kind, whose rays are ten in number, where they first part from the body, and each soon branches out into a number more.

DECADARCHUS, *Δεκαρχος*, among the Greeks, a commander of a party of ten men.

DECADE, a word used by some old writers for the number ten; and *decades*, for an enumeration by tens; the word is formed from the Latin *deci*, which is derived from a Greek word of the same import. The word has been more peculiarly appropriated to the number of books, q. d. *decades*, into which the Roman History of Titus Livius is divided. Hence also came *decadal* arithmetic, the Decameron of Boccacio, &c.

DECAGON, a plain figure in geometry, having ten sides and angles.

If all the sides and angles be equal, it is called a regular *decagon*, and may be inscribed in a circle.

The sides of a regular *decagon* are, in power and length, equal to the greatest segment of an hexagon inscribed in the same circle, and cut according to extreme and mean proportion. See *EXTREME* and *MEAN PROPORTION*.

A fortification consisting of ten bastions, is sometimes called a *decagon*.

DECALITRON, among the *Assyrians*, a piece of money used by the people of *Ephraim*, *Corinth*, and *Syracuse*, in value equal to 161 obols of Athens.

DECALOGUE, the Ten Commandments of God, engraven on two tables of stone, and given to Moses.

The word is Greek, composed of *deka*, ten, and *logos*, word, q. d. ten words. Accordingly, the Jews call them *עשרת הדברות*, the ten words, which appellation is very ancient.

The Samaritans, both in their text and version, add after the seventeenth verse of the twentieth chapter of Exodus, and after the twenty-first verse of the fifth chapter of Deuteronomy, an eleventh commandment, to build an altar on mount Gerizim, &c. But it is apparently an interpolation, to authorise their having a temple and an altar on that mountain; and to discredit, if possible, the temple at Jerusalem, and the worship there performed. It must be added, however, that, though all, both Jews and Christians, agree in the number of Ten Commandments,

ments, there is some difference as to the manner of dividing them.

The Talmudists, and Postellus after them, in his treatise De Phenicum Literis, say, that the *Decalogus*, or Ten Commandments, were engraven quite through the tables which God gave to Moles; but that nevertheless the middle of the $\square$ *Mem* final, and of the $\square$ *Semach*, remained miraculously suspended without adhering to any thing. See the Dissertation on the Samaritan Medals, printed at Paris in 1712. They add, that the *Decalogus* was written in letters of light, i. e. in luminous shining letters.

The *Decalogue* was originally delivered in two tables; one of which contains our duty to God, expressed in the four first commandments; and the second, our duty to our neighbour, enforced in the six last. The church of Rome, for a very obvious reason, hath omitted the second commandment in many of her books; and in order to preserve the number complete, divided the last into two.

DECAMERIS, a term signifying a tenth part; used by Mr. Sauveur, and some other authors, to mark and measure the intervals of sounds.

The word is formed of *δομα*, *ten*, and *μερς*, *part*.

In Mr. Sauveur's system, the *diacomeris* is the tenth part of the *heptameris*, which he makes the seventh part of the *metris*; and this is the forty-third part of the *octave*: so that the *diacomeris* is $\frac{1}{340}$ of an *octave*. See Mem. Acad. Scienc. 1701, and 1707.

DECAMERON, from *deka*, *ten*, and *meros*, *day*; a work containing the actions or conversations of ten days. Boccaccio's Decameron consists of one hundred novels related in ten days.

DECAMP. When an army raises its camp, or breaks up from the place where it lay before, they say it is *decamped*.

DECAMYRON, in the *Medicinal Writings of the Ancients*, the name of a malagma or cataplasim, consisting of ten different kinds of aromatics: these were the Indian leaf, mastic, euphorbium, spikenard, adarce, storax, pepper, ointment of nard, opobalsamum, and wax.

DECANDRIA, in *Botany*, the tenth class of plants, with hermaphrodite flowers, and ten stamina, or male parts in each. See *Tab. of Botany, Linnæan System*. The word is formed of the Greek *deka*, ten, and *andros*.

male.

Of this class of plants there are five orders; viz. the *monogynia*, containing fifty-three genera; the *digynia*, comprehending twelve genera; the *trigynia*, eleven; the *pentagynia*, fourteen; and the *decagynia*, two genera.

DECANTATION, in *Chemistry*, the act of pouring off a liquor from the dregs, &c. by gently inclining the lip, or *cantius* of the vessel; whence the word is derived.

See CANTHUS.

DECANUS, among the Romans, an officer who had ten other officers, or persons, under his charge; whence our English dean.

DECANUS, in *Astrology*, a title given to the god who

fixed at any birth, *ἀποκαταστασις*. See **ASTROLOGY**.

DECAPITE, in *Heraldry*. See DEFFAIT.
 DECAPROTI, DECEMPRIMI, among the *Ancients*, were officers who gathered the tributes, or taxes.

The word comes from *deka*, *ten*, and *spulo*, *first*; probably because the ten first, or principal persons of each community, were chosen to make the levies.

The *decapesti* were obliged to pay for the dead; or, to answer to the emperor for the quota of such as died, out of their own estates. Cicero, in his oration for Roscius, calls them *decemprini*.

DECASMUS, Δέκαμος, in *Antiquity*, the name of an action or process among the Athenians, which was brought against any person who offered a bribe. They thought it not enough to punish the person receiving a bribe, but that the person who offered it ought to be punished likewise. Pott. *Archæol. Græc.* lib. i. c. 23.

DECASTYLE, in the *Ancient Architecture*, a building with an ordonnance of ten columns in front. The temple of Jupiter Olympius was *decastyle*.

The word is formed of *δοξα*, and *κολων*, *column*.

DECEIT, *Deceptio*, or *Dolus*, in *Law*, is used for any subtle, wily shift, or trick; to which may be referred all manner of craft, subtilty, guile, fraud, sleight, cunning, covin, collusion, and practice used to deceive another by any means.

Duress is an offence both by common law and by statute. All practices of defrauding, or endeavouring to defraud, another of his right, are punishable by fine and imprisonment, sometimes pillory, &c. and there is a writ called *deceptione*, that lies for one who receives injury, or da-

A writ of *deceit* lies against attorneys, for losses sustained by their default; also against bakers, brewers, and

other artificers, for not selling good commodities, or refusing to perform a bargain: in all which cases they are by statute liable to penalties in proportion to their offence.

DECEIVED, in the *Manège*, is used when a horse upon a demi-volt of one or two treads, working, for instance, to the right, and not having yet finished above half the demi-volt, is pressed one time or motion forwards with the inner leg, and then is put to a retrace upon the left, in the same cadence with which he began. He thus regains the place where the demi-volt had been begun to the right, and works to the left. A horse may in this manner be deceived on any hand. Guillet, Gen. Dict. equestre, vol. 1.

DECEMBER, the last month of the year; wherein the sun enters the tropic of Capricorn; and makes the winter solstice.

In Romulus's year, *December* was the tenth month; whence the name, viz. from *decem, ten*: for the Romans began their year in March.

The month of *December* was under the protection of *Vesta*: *Romulus* assigned it thirty days; *Numa* reduced it to twenty-nine; which *Julius Cæsar* increased to thirty-one.

Under the reign of Commodus, this month was called, by way of flattery, *Amoranus*, in honour of a courtesan, whom that prince passionately loved, and had got pointed like an *Amoran*; but it only kept the name during that emperor's life.

At the latter end of this month they had the *Juveniles* *Indi*, and the country people kept the feast of the goddess *Vacuna* in the fields, having then gathered in their fruits, and sown their corn; whence seems to be derived our popular festival called *harvest-home*.

DECEMPEDA, Δεκάπους, ten-foot rod; an instrument used by the ancients in measuring.

The *decempeda* was a rule, or rod, divided into ten feet; whence its name, from *decem*, *ten*, and *pes*, *pedis*, *foot*. The foot was subdivided into twelve inches; and each inch into ten digits.

The *decempeda* was used both in measuring of land, like the chain among us; and by architects, to give the proper dimensions and proportions to the parts of their buildings, which use it still retains. Horace, lib. ii. od. 15, blaming the magnificence and delicacy of the buildings of his time, observes, that it was otherwise in the times of Romulus and Cato; that in the houses of private persons there were not then known any postices measured out with the *decempeda*, nor turned to the north to take the cool air.

DECEM-TALES, in *Laro*, a writ that issues directed to the sheriff, whereby he is commanded to make a supply of jurymen, when a sufficient number does not appear on a trial at bar.

DECEMVIRI, an order of annual magistrates among the Romans, created with a sovereign power to draw up and make laws for the people; thus called, because their number was ten.

To the *dogemari* was given all the legislative authority ever enjoyed by the kings, and after them by the consuls. One among them had all the ensigns and honours of the function; and the rest had the like in their turn, during the year of their *dogemariate*.

The *decemviri* were those who drew up the laws of the Twelve Tables, called thence *leges decemvirales*, which for a considerable time were the whole of the Roman law.

In the year 302, the confab *Apollus Claudius Crassinus*, and *T. Gnaeus Agrippinus*, being obliged to abdicate, the first *decemviri* were created; in the year following, two new ones were appointed to succeed them; and in the year 304, another set were to have been chosen, but that the people rose, made them lay down, and returned the confab. The excessive debauchery of *Apollus Claudius Crassinus*, one of the confab, who was first obliged to abdicate, and who had been chosen first *decemvir* three times, was the principal cause of all this. Cicero *De Finib. lib. i. Livy, lib. iii. Hæcaturus, lib. x. and Florus, lib. ii. c. 24.* relate the history.

The *decemviri* administration, however, it is to be observed, had not its first rise at the time when the authority of the consuls was devolved into the hands of the *respublici*: for, during the interregnum that ensued after the death of Romulus, the management of affairs, which the senate then took upon them, is called by *Halicanariscus*, lib. ii. *decemviri*, because the tenators, divided into tens, commanded each in their turn: that is, one of each ten, for five days successively, having the *lices*, *lictors*, &c. like the kings.

There were also military *decemviri*; and on divers emergencies, *decemviri* were created to manage and regulate certain affairs, after the same manner as boards of com-

millioners are appointed among us. Thus we find *decemviri* for conducting colonies; *decemviri* to prepare and preside at festivals in honour of the gods; *decemviri* to take care of the sacrifices; and *decemviri* to keep the Sibylls books.

Sometimes, in lieu of *decemviri*, they only created *septemviri*, or *triumviri*, or *duumviri*, &c.

DECENNALIA, in *Antiquity*, feasts which the Roman emperors held every tenth year of their reign, with sacrifices, games, largesses to the people, &c.

Augustus was the author of this custom, which was afterwards imitated by his successors.

At the same time they likewise offered vows for the emperor, and the perpetuity of his empire, called *vota decennalia*.

From the time of Antoninus Pius, we find these ceremonies marked on medals. **PRIMI DECENNALES. SECUNDI DECENNALES. VOTA SOL. DECEN. II. VOTA AVSP. DECEN. III.**

These vows must have been made at the beginning of every tenth year; for on a medal of Pertinax, who reigned four months, we find *VOTA DECEN. & VOTA DECENNALES*.

Struvius is of opinion, that these vows took place of those which the censor used to make in the times of the republic, for the prosperity and preservation thereof. In effect, they were not only made in behalf of the prince, but also of the state, as may be observed from Dion. lib. viii. and Pliny the younger, lib. x. ep. 191.

Augustus's aim in establishing the *decennalia*, was to preface the empire, and the sovereign power, without offence or restraint to the people. For, during the celebration of this feast, that prince used to surrender up all his authority into the hands of the people, who, filled with joy, and charmed with the goodness of Augustus, immediately delivered it to him back again.

DECENNARY, *Decennaria*, the limits or compass of ten *sephorah*. See **DECIMENS** and **TITHING**.

DECEPTIONE, in *Law*, a writ which properly lies for one that receives harm or damage, by him that does any thing deceitfully in the name of another.

This writ is either *original* or *judicial*. *OM. Nat. Br. fol. 50. Fitz. Nat. Br. fol. 95. See Reg. of Writs, fol. 112. and Reg. Judicial.*

DECIDUOUS, in the general, expresses a thing apt and ready to fall.

In some plants, the perianthium or calyx is *deciduous* with the flower, that is, falls off from the plant with it; in others not.

In some the leaves are *deciduous*, or fall off in autumn; in others, they remain all the winter.

DECIES tantum, a writ that lies against a juror, who hath taken money for giving his verdict.

It is so called from its effect, which is to recover ten times as much as he took.

It also lies against embracers that procure such an inquest. See **EMBRACER**.

DECIL, *Decilis*, in *Astronomy*, an aspect or position of two planets, when they are distant from each other a tenth part of the zodiac, i.e. thirty-six degrees. This is one of the new aspects invented by Kepler.

DECIMAL arithmetic, the art of computing by decimal fractions, first invented by Johannes Regiomontanus, about the year 1464, and used by him in the construction of his tables of sines; who thus introduced decimal parts in the room of *SUBALTERNALS*. They were also used by Ramus, in his *Arithmetic*, written in 1550; and before his time by our countryman Buckleus, and about the same time by Recorde. But the first person who wrote an express treatise on decimals, was Stevinus, about the year 1582.

DECIMAL fractions, are those whose denominator is 1, with one or more cyphers; as, 10, 100, 1000, 10000, &c.

Thus, $\frac{1}{10}$, $\frac{1}{100}$, &c. are decimal fractions.

In the writing of decimal fractions we usually omit the denominator, as only consisting of unity with cyphers annexed; and in lieu thereof a point, or comma, called the *separatrix*, is prefixed to the numerator. Thus, $\frac{1}{10}$ is written .1, $\frac{1}{100}$.01. So, $\frac{125}{1000}$ expresses a hundred and twenty-five parts of any thing supposed to be divided into a thousand parts.

As cyphers on the right hand of integers do increase their value *decimally*; as, 2, 20, 200, &c. so, when set on the left hand of decimal fractions, they decrease the value *decimally*; as, .2, .02, .002, &c. when set on the left hand of integers, or on the right hand of decimals, they signify nothing, but only to fill up places; thus, 15000 denotes only five tenths, and .0005 is only five units.

To reduce any vulgar fraction, as suppose $\frac{1}{2}$, to a decimal fraction of the same value; add cyphers at pleasure to

the numerator, and divide by the denominator; as thus,

$$\begin{array}{r} 8 \overline{) 5000} \\ 1025 \end{array}$$

And therefore $\frac{1}{2}$, or, $\frac{625}{1000}$, is a decimal of the same value with the former fraction.

Some vulgar fractions can never be reduced into decimals, without defect; as $\frac{1}{3}$, &c. in those cases, the greater number of places the decimals are continued to, the more is the defect diminished, in a tenfold proportion.

Thus, $\frac{1}{3}$ expressed in decimals is, $.333333$ ad infinitum. Such decimals are very properly called circulating decimals, because of the continual return of the same figures; and they may be called indeterminate or infinite decimals, by way of distinction from those where the reduction leaves no remainder, and which are therefore called finite or determinate decimals. See **REPEATING**.

By the rule above given, the parts of any integer may be easily reduced into decimals. Thus, 5s. is $\frac{5}{20}$, or, $\frac{1}{4}$, or, $\frac{25}{100}$ of a pound sterling; 6d. is $\frac{6}{12}$, or, $\frac{1}{2}$, or, $\frac{50}{100}$ of a pound; and 5s. 6d. is $\frac{5}{20} + \frac{6}{12} = \frac{275}{100}$. Or the decimal of a mixed number may be readily obtained by reducing the number of the lowest species to the decimal of the next above; add to this the number of that species, if there be any, and reduce the sum to the next higher species, adding to the number found the number of that species given in the question; and thus proceed till you arrive at the proposed integer: 4 l. 7 s. 3 d. are equal to 4.322916 l. for 3s. is $\frac{3}{20}$, or, $\frac{15}{100}$ d. to which add 7 d. and $\frac{7}{100}$ is equal to $\frac{77}{100}$, or, $\frac{775}{1000}$ &c. to which

add 4 l. and $\frac{4000}{1000} + \frac{775}{1000}$ &c. is equal to $\frac{4775}{1000}$, or, 4.775 l. The same process may be easily applied to the decimal parts of any other integer, as weights, measures, and times.

The common operations in decimals are performed as in the vulgar rules, regard being had only to the particular notation, to distinguishing the integral from the fractional part of a sum.

In Addition and Subtraction of DECIMALS; the points being all placed under each other, the figures are to be added, and subtracted, as in common arithmetic; and when the operation is done, so many figures of the sum, or the remainder, are to be noted for decimals, as there are places of decimals in the greatest given numbers. An example will make this clear.

Addition of Decimals. Subtraction.

43791	59.271	From 67.10
792	15.040	Take 30.8754
6124	3.704	Rem. 36.2246
053	12.009	
10	7.5	From 25.1402
2		Take 13.07
2,19531	97.611	Rem. 12.0762

For Multiplication of DECIMALS, observe to cut off just so many decimal parts from the product as there are decimals in both factors. The work is the same as in integers. Thus,

Multiplication of Decimals.

1472	395	3650
175	122	621
7360	730	3650
10304	730	7300
1472	395	21900
20257600	2044530	2266650

Note. In the first and second examples, the products only amount to six and five places; for which reason cyphers are prefixed, to make up the number of decimal places in the two factors respectively.

Hence, to multiply a decimal by unit with any number of cyphers, is only to remove the *separatrix* so many places to the right as there are cyphers annexed.

In Division of DECIMALS, proceed in all respects as in dividing of integers; and, when the operation is done, mark as many places in the quotient for decimals, as with the number of decimals in the divisor, are equal to the decimal places of the dividend.

22,8030(365	22,8030(365
66	66
143	143
132	132
110	110
110	110
...	...
22,8030(365	73,283,219(1,13
66	73 2
143	100 1
132	73 2
110	26 99
110	21 60
...	...
	5 03

Hence, to divide a decimal by unit, with any number of cyphers, is only to remove the separatrix (so many places to the left as there are cyphers annexed).

But there are certain cases in division of decimals, which require some farther management: as, first, where the divisor is a decimal fraction, and the dividend is an integer; add, or annex, as many of either more cyphers to the dividend, than there are places in the divisor: thus, $365/22,000(602$. For there being three places of decimals in the divisor, and four in the dividend, there will be but one in the quotient. Secondly, Where the divisor is a mixed number, and the dividend a whole number, add at least as many cyphers to the dividend, as there are places in the divisor: thus, $365/22,000(602$. Thirdly, Wherever the divisor is bigger than the dividend, annex cyphers to the latter; thus, $30,5/22,000(602$.

For the valuation of DECIMALS; multiply the given decimal by the number of parts contained in the proposed integer, proceeding from the higher to the lower if there be a remainder, and you will have the value required at the left of the separatrix. Thus, 7854 is equal to $15 \text{ s. } 8 \text{ d. } 16 \text{ f.}$

785	78 of a yard = 2 feet,

DECIMAL scales, in the general, denote any scales divided decimally; but particularly certain scales of money, weights, and measures, made from tables so called, to expedite decimal arithmetic, by shewing by inspection the decimal fraction of any part of money, weight, or measure. See SCALE.

DECIMATION, a punishment which the Romans used to inflict on the soldiers who had quitted their post, raised a mutiny in the camp, behaved themselves cowardly in the fight, or otherwise failed in their duty; for which every tenth man was put to death as an example to the rest.

The manner of decimating was thus: the general assembled the whole camp; then the tribune brought to him those that were guilty, and impeached, and reproached them with their cowardly actions, and baseness, in the presence of the whole army; then putting their names into an urn, or a helmet, as many were drawn out as made the tenth part of the whole number, and these were put to the sword, and the others saved.

This was called *decimatio*, a word of the ancient Roman militia, who, to punish whole legions, when they had failed in their duty, sometimes also made every tenth soldier draw lots, and put him to death for an example to the others.

As the Romans had their *decimatio*, they had also the *centimatio*, and even *centimatio*, when only the twentieth or hundredth man suffered by lot.

This practice has been occasionally recurring in modern times: as, particularly, in France, for the punishment of the garrison of Treves in 1675, who capitulated and surrendered that place in opposition to the remonstrance of the Marshal de Crequi, who commanded there.

DECIMAE. See TITHES.

DECIMIS servandis pro passivibus alienigenarum, a writ, yet Vol. II. N° 91.

extant in the register, which lay against those that had farmed the priors' lands of the king, for the redress of the parish, to recover his title of them. Reg. of Writs, fol. 179.

DECINERS, DECENNIERS, or DOZINERS, derived from the French *decime*, i. e. *decim*, *ten*; in the ancient monuments of our law, are such as are wont to have the oversight and check of the burghs, for maintenance of the king's peace; the limits of whose jurisdiction were called *decima*, and *decima*.

They seem to have had very large authority in the Saxon times; taking cognizance of causes within their circuit, and redressing wrongs by way of judgment. Thus Bilton, c. We will that all those who are fourteen years old shall make oath, that they will be sufficient and loyal to us; and neither be felons, nor assenting to felons; and we will, that all profess themselves of this or that dozen, and make answer for the behaviour by those or those dozens, except religious persons, clerks, knights eldest sons, and women.

A dozen now seems to be no more than a feet: for in feet only this oath is administered by the steward, and taken by such as are twelve years old and upwards.

DECIPHERING, or DACTYLOGRAPHY, the art, or act, of finding the alphabet of a cipher, or of explaining a letter written in cipher.

Every language has peculiar rules of deciphering; which depend not only on the form of its characters, but likewise on the place, order, combination, frequency, and number of the letters. The general theory of this art may be comprized in the following propositions: one word is to be compared with another, in order to observe both their resemblance and their difference; no word can be without a vowel; a word of one letter is always a vowel, or a consonant with an apostrophe; the vowels recur much more frequently than the consonants; double vowels may be produced at the beginning of a word, but not double consonants; and double characters in this place are always vowels; short words of two or three letters have two or three vowels, or one or two consonants; and in words of this kind the vowels are most easily discovered: when double consonants are preceded by a single letter, that letter is a vowel; one vowel is often joined with another in words abounding with diphthongs: the consonant that always precedes or follows double consonants, is one of the liquids *l*, *m*, *n*, *r*; the consonant *g* is always followed by the vowel *u*, though *u* may be joined with other letters. When two different characters occur, the latter of which is often joined with various letters, and the former never found either by itself, or followed by any other letter; those two are *qu*; which letters are almost always followed by a vowel: one vowel and one consonant recur more frequently than others. The particular theory of deciphering depends on the peculiar structure of different languages to which it is applied. The curious, who desire farther information on this subject, may consult the Art of Deciphering deduced from principles, and explained by examples in the German, Dutch, Latin, English, French, Italian, and Greek languages, by David Arnold Conradus, in the twelfth volume of the Gentleman's Magazine for 1742. See also M. de Grave's Introduction to Philology, cap. xxxv. Leyden, 1732.

B. Porta published a treatise on this subject; and a collection of letters written in cipher, and deciphered by Dr. Wallis, are now in the Library of Oxford.

DECK of a ship, from *decker*, Dan. *to cover*; a kind of planked floor, connecting the sides, and serving as different platforms to support the artillery, to lodge the men, and to preserve the cargo in merchant-vessels.

A ship is said to have two or three decks, when it contains two or three stories. Ships of the first and second rates are furnished with three whole decks, reaching from the stem to the stern, besides a fore-cabin and a quarter-deck, which extends from the stern to the main-mast. There is also another deck above the lower part of the quarter-deck, called the poop, and serving as a roof for the captain's cabin or couch. Inferior ships of the first of battle have two decks and a half; and frigates, sloops, &c. have one gun-deck and a half, with a spare deck below to lodge the crew. The frame of the lower-deck is stronger than that of the others, because ships are broader at the lower deck than at the next above it, and it also bears the heaviest cannon.

The decks are formed and sustained by the BEAMS, the CLAMPS, the WATERWAYS, the CARLING, the LEDGES, the KNEES, and two rows of small pillars, called STANCHIONS.

DICK, *Fluyt*, is one that lies even in a right line, fore and aft, from stem to stern.

The frame lay, a deck lies cambering, when it doth not lie level, but higher at the middle than at either end.

cambered *deck* is by no means proper for a man of war. Also, if the ship's keel be bent in the middle upwards (which may happen from her lying a-ground on a place, where neither her aft nor fore-part touch it, and from many other reasons taken from her make), they say, *she is camber-keel'd*.

DECK, *Half*, is a space under the quarter-deck of a ship of war, between the foremast bulk head of the fleerage, and the fore-part of the quarter-deck. In the Northumberland colliers, the fleerage is called the *half-deck*, and is usually the habitation of the ship's crew.

DECK, a *Kept*, is that made of cordages interwoven, and stretched over a vessel that has no *deck*, through which it is easy to annoy the enemy who comes to board her, and has leaped thereon. These are little used but in merchant-vessels, to defend them from the corsairs.

DECLAMATION, a discourse or speech made in public, in the tone and manner of an oration.

Among the Greeks, *declamation* was the art of speaking indifferently on all subjects, and on all sides of a question; of making a thing appear just that was unjust; and of triumphing over the best and soundest reasons. Such sort of *declamations*, M. de St. Evremont observes were fit only to corrupt the mind, by accustoming men to cultivate their imagination rather than to form their judgment, and to seek for verisimilitudes to impose upon, rather than solid reasons to convince, the understanding.

It is said that a certain orator, named Plotius Gallus, first introduced the use of *declamations* at Rome. In this way Cicero formed himself for eloquence. The term frequently occurs both in Horace and Juvenal.

Among us, *declamation* is restrained to certain exercises, which schoolers perform, to teach them to speak in public.

We say, a *declamation* against Hannibal, against Pyrrhus, the *declamation* of Quintilian, &c.

In the colleges of the Jesuits, *declamations* are little theatrical or dramatic performances, consisting of a few scenes, not divided into acts, rehearsed by the students by way of exercise, and to form them for speaking in public. Such *declamations* are the most useful exercises performed in the colleges.

DECLARATION, in the *Custom-House and Commerce of France*, contains a particular account or invoice of what is contained in the bales or casks, brought to the officer for entrance inward or outward.

DECLARATION, in *Law*, the act of shewing in writing the cause of complaint of the demandant, or plaintiff, against the defendant, where he is supposed to have received some wrong.

This ought to be plain and certain, both because it impeacheth the defendant, and also compels him to answer thereto. It must also set forth the plaintiff's and defendant's names, the nature and cause of the action, &c. and the damage received. See **COUNT**.

DECLARATION of fidelity, is used for a confession, which the Quakers, who scruple taking the oath of supremacy, &c. are obliged to make and subscribe in lieu thereof.

His treason is a solemn promise to be true and faithful to king George; with a detestation and horror of that damnable position, that princes excommunicated by the pope, or any other power, may be deposed or murdered; and a *declaration*, that no foreign prince, or power, has any right, jurisdiction, or authority, in this kingdom.

There is also a *declaration* against transubstantiation made and subscribed by those who qualify for offices; 25 Car. II. c. 2. and a *declaration* against popery to be made and subscribed by the members of both houses of parliament, by dissenters qualified according to the toleration act, &c. &c. in which they renounce transubstantiation, the invocation of saints and of the Virgin Mary, and the sacrifice of the mass, and every kind of evasion, and mental reservation, as well as dispensation or absolution. 30 Car. II. stat. 2. c. 1.

DECLARATIONS, Clerk of the, See **CLERK**.

DECLARATORY part of a Law, is that by which the rights to be observed, and the wrongs to be avoided, are clearly defined and laid down. This depends not so much on the law of revelation or of nature, as on the wisdom and will of the legislator.

DECLARATORY part of a Statute, is that which relates to obsolete or disputable customs; in which case the parliament has thought proper, in *perpetuum rei testimonium*, and for avoiding all doubts and difficulties, to declare what the common law is and ever hath been.

DECLENSION, in *Grammar*, the inflexion of a noun, according to its diverse cases. See **CASE**, **NOMINATIVE**, &c.

Mr. Harris observes, that the Peripatetics likened the noun in its primary and original form, to a perpendicular line; and the variations from the nominative were considered as if that line fell from its perpendicular to an oblique position; and hence these variations were called *oblique*, *casus*, *cases*, or *fallings*. Grammarians were thus led to call the method of enumerating the various cases of a noun, *oblique*, *declinatio*, a *declension*; because it was a sort of progressive descent from the noun's upright form, through its various declining forms. Hermes, p. 277, 278.

The *declension* of nouns is a different thing in the modern languages, which have not properly any cases, from what it is in the ancient Greek and Latin, which have.

Declension, in languages wherein the nouns admit of changes, whether in the middle, beginning, or end, is properly the expelling or recting all those changes in a certain order, and by certain degrees, called *cases*.

In languages wherein the nouns do not admit of changes in the same number, *declension* is the expelling of the different states or habitudes a noun is in, and the different relations it has: which difference of relations is marked by particles called *articles*: as, *a, the, of, to, from*, &c.

DECLENSION of a distance, is when it is past its height, and the symptoms abate.

DECLINATION, in *Astronomy*, the distance of the sun, a star, planet, or other point of the sphere of the world, from the equator, either northward or southward. It is the same with **LATITUDE** in geography.

Declination is either *real* or *apparent*, according as the real or apparent place of the point is considered.

The *declination* is an arch of a great circle, as GS (*Tab. Astronomy*, fig. 4.), intercepted between a given point, as S, and the equator A Q, and perpendicular to the same. Consequently, the circle, by whose arch the *declination* GS is measured, passes through the poles of the world. The *declination* of a star, &c. is found by first observing the altitude of the pole, as PR (*fig. 5.*) This subtracted from 90° gives the height of the equator A H. Then, the meridian altitude of the star HD being observed, if it be greater than the altitude of the equator A H, the latter subtracted from the former leaves the *declination* northward A D; or, if the altitude of the star H T be less than that of the equator H A, the former subtracted from the latter leaves the *declination* southward T A.

E. gr. Tycho at Uranibourg observed the meridian altitude of the Cauda Leonis:

HD	50°	59'	0"
HA	34	5	20
<i>Declinat. therefore, AD</i>			
	16	53	40

If the star be in the quadrant Z R, then the least altitude M R subtracted from the altitude of the pole P R leaves the distance from the pole P M; which subtracted again from the quadrant P Q, leaves the *declination* M Q. E. gr. M. Couplet observed P M 2° 18' 50", which subtracted from 90° leaves M Q 87° 41' 10". And by this method are constructed the tables of *declinations* of the fixed stars given us by Ricciolus and Dechales. In the construction of tables of *declinations* of the sun, planets, and stars, regard should be had to REFRACTION, ABERRATION, NUTATION, and PARALLAX. By comparing the ancient observations with the modern, it appears, that the *declination* of the fixed stars is variable; and that differently, in different stars. For in some it increases, and in others decreases, and that in different quantities.

It has been greatly disputed among the latter mathematicians, whether or no the *declination* and the obliquity of the ecliptic be variable. See **ECLIPTIC**, and **OBLIQUITY**.

N. signifies North Decl.
and S. South Decl.

This table was calculated by Mr. Ferguson for the noon of every day of the second year after leap-year, on the meridian of Greenwich; which is a mean between those of leap-year itself and the first and third years after. See a table of *declination*, &c. annually published in the *Nautical ALMANACK*.

DECLINATION, Circle of, is a great circle of the sphere passing through the poles of the world; and on which the *declination* of a star is measured; such is P D G K, passing through the poles P and K, *Tab. Astronomy*, fig. 4.

DECLINATION, Parallel of, is an arch of the circle of *declination*, whereby the parallax of the altitude increases or diminishes the *declination* of a star.

DECLINATION, Refraction of, an arch of the circle of *declination*, whereby the *declination* of a star is increased or diminished by means of the refraction.

DECLINATION, of the axis, or compass, is its variation from the true meridian.

DECLINATION, of a vertical plane, or wall, in Dialling, is an arch of the horizon, comprehended either between the plane, and the prime vertical circle, if you account it from east to west; or between the meridian and the plane, if you account it from north to south.

There are many ways given by authors for finding the *declination* of planes: the most practicable way is by a *declinator*.

DECLINATOR, or DECLINATORY, an instrument in dialling, whereby the *declination*, inclination, and re-
clination of planes is determined.

Its structure is as follows: on a square wooden board A B C D (*Tab. Dialling*, fig. 1.) describe a semicircle A E D, and divide the two quadrants thereof A E and E D into 90 degrees each, beginning from E, as in the figure. Then, having fixed a pin in the centre F, fit a wooden ruler H I upon the same, moveable thereon, with a box and needle K, as shewn under COMPASS.

Now, to apply this, in taking the *declination* of a plane: apply the side A D of the instrument to the plane proposed, as M N (fig. 2.); and move the ruler F G, with the compass G, this way and that, about the centre F, till the needle rest upon the line of the magnetical meridian of the place. Now, if the ruler in this situation cut the quadrant in E, the plane is either northern or southern: but if it cut between D and E, the plane declines to the west; or, if between A and E, to the east by the quantity of the angle G F E.

The same instrument will also serve to take the inclinations and reclinations of planes. To this end instead of the ruler and needle, a thread with a plummet is fixed on a pin in the centre F: then the side B C of the *declinator* A B C D, being applied to the proposed plane, as I L (fig. 3.), if the plummet-line F G cut the semicircle A E D in the point E, the plane is horizontal: or if it cut the quadrant E D in any point at G, then will E F G be the angle of inclination: lastly, if applying the side A B to the plane, the plummet cut E, the plane is vertical. Hence, if the quantity of the angle of inclination be compared with the elevation of the pole, and equator, it is easily known whether the plane be inclined, or reclined. See INCLINATION and RECLINATION.

DECLINATORY Plan, in Law. See BENEFIT OF CLERGY.
DECLINERS, or DECLINING dials, are those which cut either the plane of the prime vertical circle, or the plane of the horizon, obliquely.

If we conceive the plane of the prime vertical circle to revolve a little upon a right line drawn from zenith to nadir, the plane will become declining; nor will it be any longer cut at right angles by the meridian, but by some vertical circle passing through the intermediate points. After the like manner an horizontal plane will be brought to decline, if revolving on the meridian line, not part of it be raised a little towards the zenith, and the other depressed towards the nadir.

The use of declining vertical dials is very frequent, because the walls of houses, whereon dials are commonly drawn, do generally decline from the cardinal points. Incliners and decliners, and especially decliners, are very rare. See DIAL.

DECLIVIS, in Anatomy, a muscle of the abdomen, called also *obliquus descendens*.

DECLIVITY. See ACCLIVITY.

DECOCTION, the act of boiling any substance in water, to extract the virtues out of the same for some medicinal purpose; or the water itself, in which the substance has been boiled.

Decoctio is mostly employed about balsamics, detergents, and cathartics; for it is not so proper for cephalics, &c. as it exhales the more volatile parts, in which the virtues of all those ingredients consist. The harder bodies, as woods, dried roots, &c. require moist boiling; but herbs and seeds need only be scalded. All those *decoctions* which are refrigerant, and most of the cathartics, may for the greater elegance be clarified: but all such as are

emollient, and intended to consist of the soft and mucilaginous parts of simples, are by no means to be so managed.

M. Boulduc assures us from his own experience, that the infusions of vegetable purgatives act better, and produce better effects, than their *decoctions*; which he attributes to this, that the purest and most active principles of those bodies are diffused and evaporated by a boiling heat. *Memoires de l'Academie Royale des Sciences*, an. 1710. And M. Baume, in his *Elements of Pharmacy*, observes, that the infusion of Peruvian bark made without heat contains more of its principles than the *decoction*: because heat separates and precipitates a considerable quantity of resinous substance, of which the bark consists: and it is observed in general, that *decoctions* ought not to be employed but when absolutely necessary, or when the same principles and the same quantity of these principles cannot be obtained by an infusion without heat.

DECOLLATION, laceration, a term frequently used in the phrase, *decollation* of St. John Baptist, which denotes a painting, wherein is represented the Baptist's head, struck off from his trunk; or, the feast held in honour of this martyr.

DECOMPOSITE Leaf, in Botany. See LEAF.

DECOMPOSITION, in Chemistry and Pharmacy, the same with analysis or resolution; viz. the reduction of a body into its principles, or component parts.

DECOMPOSITION is sometimes taken for any sort of resolution, or separation of parts; but, in propriety, *decomposition* is a chemical process, in order to a separation of the heterogeneities, or impurities, from any matter.

Tradition, founded on repeated experiments, is a much safer way of arriving at the knowledge of the properties of a plant, than any chemical analysis, or *decomposition* of its principles. See MEDICINE.

DECOMPOSITION is used by Boyle, Newton, and other English authors, to signify the composition or junction of two or more bodies, which were previously compounded of other parts.

DECORATION, in Architecture, any thing that adorns and enriches a building, church, triumphal arch, or the like, either without-side, or within.

The orders of architecture contribute greatly to the *decoration*; but then the several parts of those orders must have their just proportions, characters, and ornaments; otherwise the finest order will bring confusion rather than richness.

Decorations in churches are paintings, vases, festoons, &c. occasionally applied to the walls; but that with so much skill, as not to take off any thing from the form of the architecture; as is much practised in Italy, at the solemn feasts.

DECORATION is more properly applied to the scenes of theatres, which must be frequently changed, conformably to the subject.

The ancients had two kinds of *decorations* for their theatres: the first, called *scenifera*, having three sides, or faces, which were turned successively to the spectators; the other, called *scenifera*, shewing a new *decoration* by drawing, or sliding another before it.

This latter sort is still used, and apparently with much greater success than among the ancients, who were obliged to draw a curtain whenever they made a change in the *decoration*; whereas on our stage the change is made in a moment, and almost without being perceived.

DECORTICATION, the act of peeling, or unbulking roots, seeds, fruits, branches, &c. or of freeing them from their barks, rinds, husks, or shells.

DECORUM, Decor, in Architecture, denotes the suitability of a building, and of the several parts and ornaments thereof, to the place and occasion.

Vitruvius is very terse in this point, and gives express rules for appropriating, or suiting the several orders to their natural characters: so, e. gr. as that a Corinthian column may not be set at the entrance of a prison, or gatehouse; nor a Tuscan, in the portico of a temple; as some have done among us, in breach of *decorum*. Even in the disposition of the offices of our ordinary houses, we find grievous offences against *decorum*; the kitchen being often where the parlour should be, and that in the first and best story, which should have been condemned to the lowest, and worst.

DECOUPLE, in Heraldry, the same as uncoupled, i. e. parted, or fowered.

Thus, a chevron *decoupled* is a chevron wanting too much towards the point, that the two ends stand at a distance from each other.

DECOURS, } in Heraldry. See DECREMENT.
DECREASANT, }

DECOY, a place made fit for catching of wild fowl.

Hence also a *decoy-duck* is one that flies abroad, and

lights

lights into company of wild ones, and, being become acquainted with them, by her allurements draws them into the *lure* place, where they become a prey. See *Fowl*.

The *Acary* is usually made where there is a large pond, surrounded with weeds, and behind it a marshy and uncultivated country, near the wild-fowl nearly frozen deep during the wintering. They are composed of several pipes, as they are called, which lead up a narrow ditch, that changes into a fountain-net. Over these pipes, which become narrower from the first column, is a long continuous arch of netting supported on hoops. The net is always a pipe of the same size, almost every yard thick and as long as the ditch, and is made of the same material as the hoops, which pipe is fixed at the bottom and the *Acary* men sit on hoops on the forward end of the ditch to prevent any birds from reaching their fountains. The net is made of reeds, are placed at various distances, some close pipes, in such a manner that it is impossible for the birds to pass, to feel the pipe, they then have a small net at the end of the ditch, which is made of the same material as the netting, when the birds are in the ditch, the *Acary* always stands behind their wings, in their flight, may be heard at a great distance. The rising of the *Acary* is in *Schamphur*, called *Acary*. The *Acary* pipes are fed with a small pipe, which is driven in from the fountain over the *Acary*, to bring them forwards into the pipes, and to allow the wild-fowl to follow. They sit on frames at the end of the ditch, after hearing the whistle of the *Acary* men, and enticed by the humming, and to drive under water, until the wild-fowl fly on, and are taken in the net. When they are in such a plenty that as not to follow the *Acary* ducks, a small net is made in pairs between the *Acary* approaching gradually nearer and nearer to the pipe-net, which rises the situation of the wild-fowl, and makes them to advance forward; at length the *Acary* men appear behind a screen, and drive them into the net.

The general season for catching wildfowl in *deers* is from the latter end of October till February. The act of to Geo. II. cap. 32. forbids taking them from June 1 to Oct. 1, under a penalty of five shillings for every bird destroyed within that time. The Game-licence also, which principally supply the London markets, are renewed from 25 to 27th. Pennant's Zoology, vol. II. p. 502. 320. 1776.

[illegible]

DIAPHR. DIAPHRAGM. an *inter.* or *recl.* made by a superior power, for the regulation of an inferior. The commerce between soul and body, F. Malebranche observes, has no other vinculum, or connection, but the efficacy of the divine *dictate*. Second causes only execute the *decrees* of Providence.

The doctrine of the Calvinists has been charged with implying that God concurs to sin by a positive *decretum*; in that, if crimes were not ordained by an antecedent *decretum*, God could not foresee the events.

Decrees of councils are the laws made by them to regulate the doctrine and policy of the church.

Decretum was originally used by the lawyers for any thing ordained by the prince, upon consideration of a cause. But the canonists now restrain the word *decretum* to the ordinances of popes, which form the first part of the canon-law, as the *canon* is to what is ordained by councils.

Decrees in chancery are the determinations or sentences of the lord chancellor, upon full hearing, and weighing the merits of the cause. See CHANCERY.

DECREMENT, or **DECREASANT**, in *Hirshky*, denotes the wane, or decrease of the moon, when she is receding from the full towards the new.

In this phase the is called, in blazon, a *moon-decreffant*, or *en decressant*: since to call it a crescent, would be improper, as that term denotes an internate. The moon looking to the left side of the escutcheon, is always supposed to be *decreffant*: when she faces the right she is crescent, or in her growth.

DECREMENT, *equal, of life*. See COMPLEMENT *of life*.
DECREPITATION, in *Chemistry*, the operation of drying
Vol. II. N^o 61.

and skimming fats over the fire, continuing till such time as they cease to crackle.

Decoupling is also applied to the noise or crackling of the film during the operation.

The design of this operation is to free the felt of its superfluous moisture; but the felt is hereby rendered porous, and apt to imbibes moisture; that unless it be kept very close afterwards, it soon moistens again.

DECTA, in *Biology*, a name used by some authors for the garden-beet.

The *decretals*, *littere decretales*, comprise the second part of the *CANON-LAW*.

All the sermons attributed to the pope before his death, in 1315, are essentially large-fifteenth. They are supported by the fact that the general collection of his sermons, printed at Seville, by order of the king, contains the text of the same of Innocent's successor, Gregory X. The first was published by Barahol, Bishop of Metz, in the middle century. Pope Gregory IX, in the thirteenth century, procured a compilation to be made of all the *sermonei*, a canonical collection of his predecessors, in accordance with the Riforma of Damiano, his chaplain, which is the only collection authorized by the holy see to be read in churches.

DECEBIUS, *in Medicine*, the manner of lying or re-
fusing in bed.

Every physician knows that the principal indications of the strength or weakness of the motive faculty are taken from the *desires*; and indeed we may with very good reason judge of the state of that faculty, by the *desires* itself; in the consideration of which two many circumstances enter for us to notice here.

DECUMANNI *Dentii*, a term used by the Latin writers on heraldry to express that foremost line in armor, which we call dancette, or dancetté. See DANCETTÉ.

It is a kind of indented line, but is very large, and has very few teeth, commonly no more than eight. It is supposed to have been in its origin no other than the lesser M., with its two legs extended from one side of the fin to the other.

DECOUPLE, in *Arithmetica*, a term of relation, or proportion, implying a thing to be ten times as much as another.

DECURIO, the chief, or commander of a *decuria*, both in the Roman army, and in the college or assembly of the *decemviri*. See **DECURY**.

DETURIO, *maestripala* was a name given to the senators of the Roman colonies.
They were called *deturios*, because their court or com-

They were then *comitatus*, because each town or company always consisted of ten persons. See Livy vii, by means hereof, the ancient Italy, at that time as had colonies, had a share under Augustus, in the election of the Roman magistrates; the *decuriones*, or senators of those cities, having suffrages therein, which they sent, led up to Rome, a little before the election.

DEUS was also a name given to certain priests, perhaps, as it should seem, for some particular sacrifices, or other religious ceremonies; or for the sacrifices of private families and houses, as Servius testifies, who thence derives their name.

Be the origin of the name what it will, we have an inscription in Gruter, which confirms what we have said of their functions: ANCIENSIS, CIVIS AEO, Q. TER. IN. ALDE. DECVRII. ADLECTVS. EX. CONSIG. DECVRIOSVM. FAMILIAR. VOLVNTATE. Which proves that there was a *domus* in the house of a private person, Q. Terentius.

DECURIO, in Roman Antiquity. See CAMPIDURIO.
DECURY, ten persons ranged under one chief, or leader,
called the *Decurie*.

The Roman cavalry was divided into *deviæ*.
 Romulus divided the whole Roman people into three
 tribes; over each of which he appointed a *tribune*; each
 tribe he subdivided into ten *centuries*, with *centurions* at
 their heads; and each century he subdivided further into
 ten *deviæ*, over each of which a *devæ* commanded.

DISCUSSION, in *Geometry*, *Optics*, and *Anatomy*, the points wherein two lines, rays, or nerves, cross, or intersect each other; or the action itself of crossing. The optic nerves of both eyes are commonly supposed to *decussate* before they reach the brain; to which *decussation* many authors attribute it, that we see single with two eyes; though others deny this *decussation*.

The rays of light *decompose* in the crystalline, before they reach the retina.

So that pope Leo's bull was only a renovation of an ancient right. Pref. stat. lib. i. cap. 2.

DEFENDERE is a *manu*, to wage law; by denying the accusation upon oath. *Et si forte forisfactus sit talium negotiorum, et forisfactus sit in factu, et si deinde se defendere unica manu ad unum uirum rationem habere debeat, et si deinde se defendere unica manu ad unum uirum rationem habere debeat, et si deinde se defendere unica manu ad unum uirum rationem habere debeat.* See *Maxims*.

DEFENDERS were anciently notable dignities, both in church and state; whose business was, to look to the preservation of the public weal, and to protect the poor and helpless, and to maintain the interests and duties of churches, and religious houses.

The council of Chalcedon, can. 2. calls the *defensor* of a church, *advocatus*. Codin. De Officiis Aula Comit. makes mention of *defensores* of the palace; so does Bollandus, Act. S. Januarii, tom. 2. p. 304. There were also a *defensor* of the kingdom, *defensor regis*, *defensor* of cities, *defensor* of stations, *defensor* of the people, *defensor* of the poor, fatherless, widows, &c.

About the year 420, each parochial church began to have its *defensor*; which custom was afterwards introduced into other churches, and continued to later days under other names; as those of *advocatus*, and *advocatus*. See *Advocatus*, and *Advocatus*.

In the year 400, we find the council of Carthage among the *defensores* of the number of *defensores*, to be 10, advocates who were in office; and that it might be allowed them to enter, and to search the cabinets and papers of the judges, and other civil magistrates, whenever it should be found necessary for the interest of the church.

DEFENDING, is *Fortification*, is ordinarily synonymous with *defence*.

Thus, we say, the bank *defends* the curtain, and the opposite face of the bastion. *defendit* harles, or *defendit*, the bank, or crown-work. The ancient fortifications are easily taken; there being nothing to *defend*, that is, to bank them.

When they say, the bank *defends* the curtain, they mean, not only that it is *defence* of the curtain, but, also, that it prevents the approaches; that is, such as are posted on the bank of a bastion, can fire any that comes to attack the curtain; and can shoot them, or prevent their approaching it.

Inter DEFENSUM *defensio* is the angle CIE (Tab. Fortific. tit. 2. fig. 12.) made by the lesser line of *defence* with the curtain.

Quasi DEFENSUM *defensio* is the angle COF, formed by the two lesser lines of *defence* CO, and FO.

The lines, or files, of the rampart, or wall, are *defended* by musquets, or carbines; as made easy, cheap, and commodious, than cannon.

DEFENSIVE, in *Medicine* and *Chirurgia*, denotes a bandage, plaster, or the like, used in the cure of a wound, to moderate the violence of the pain, the flux of blood, and the access, or impression, of the external air.

The cauterization performed, the wound is covered with lint, and the eye with a *defensive*, and triangular compress. For the first dressing of the entorse, M. Digne used a little *defensive* made of the white of an egg, oleum rosmarini, and alum-powder.

DEFENSIO, that part of any open field or place, that was allotted for corn and hay, and upon which there was no common or feeding, was anciently said to be *defensio* of any meadow ground, that was laid in for hay only. It was likewise the time of a wood, where part was enclosed and fenced up, to secure the growth of the underwood from the injury of cattle.

DEFENSOR. See *Advocatus*.

DEFERENT, *DEFERENS*, in *Anatomy*, is applied to certain vessels of the body, appointed for the conveyance of humours from one place to another.

Testis DEFERENTIS are two white folded tubes, one lying on the right side, and the other on the left; from the epididymis, of which they are continuations; each of them runs up in the cellular vagina of the spermatic vessels, as high as the opening in the abdominal muscles, the blood-vessels lying forward, and the *testis deferens* behind them. These vessels convey the seed as fast as it is secreted and prepared in the testicles, &c. into the *ejacula seminalia*; thence to be deposited till an emission is required. See *Testis*, *ductus* (*Spermaticus*) fig. 1. lit. a. fig. 2. lit. a. fig. 3. lit. a. fig. 4. lit. a.

The passage of the *semen deferens* into the *ejacula seminalia* is very particular. These canals are incurved behind the bladder, and their contracted extremities unite at that place. They unite in an angle, and run between

the contiguous extremities of the *ejacula*; and this union is so close, that the adhering portions seem only to form the middle septum, between two small tubes; each of which is formed partly by the extremity of one *semen deferens*, and partly by that of the neighbouring *ejacula*.

Some call them the *ejaculatory vessels*. They are white, nervous, and round, situate partly in the testum, and partly in the abdomen.

DEFENSIO, in *Astronomy*, in the *Ancient Astronomy*, a circle invented to account for the eccentricity, perigee, and apogee, of the planets.

As the planets are found differently distant from the earth, at different times, it was supposed, that their proper motion was performed in a circle, or ellipse, which is not concentric with the earth; and this eccentric circle, or ellipse, they called the *defensio*; because, passing through the centre of the planet, it seemed to support or sustain it in its orbit.

The *defensio* are supposed differently inclined to the ecliptic, but none more than eight degrees, excepting that of the moon, which is in the plane of the ecliptic itself, and is cut differently by the *defensio* of the other planets in two places, called *nodes*.

In the Ptolemaic system, the same *defensio* is also called the *defensio* of the *apogee*; because it traverses the centre of the epicycle, and seems to sustain it.

DEFECT, or *DEFECTUS*, is a term used, by the French historians, to denote a head whose head is cut off smoothly, in which it differs from *cratus*; where the head is, as it were, torn off, and the neck left ragged.

DEFICIENT interval, in *Astronomy*, is used for an interval less than the true by a *commata*. See *DEFRAVAT*.

DEFICIENT numbers, are such whole parts, added together, make less than the integer, whose parts they are. See *NUMBERS*.

Such, e. g. is 8; whose quaternary parts are 1, 2, and 3; which, together, only make 6. See *ABUNDANT Numbers*.

DEFICIENT hyperbola is a curve of that denomination, having only one asymptote, and two hyperbolic legs running out terminally towards the side of the asymptote, but contrary ways. See *CURVE*.

DEFILE, in *Fortification*, a narrow pass or way, through which a company of foot, or foot, can pass only in file, by making a small front; so that the enemy may take an opportunity to stop their march, and to charge them with so much the more advantage, because the front and rear cannot reciprocally come to the relief of one another.

The word is formed from the French *defiler*, to *unwind*, or *unroll*.

The term *defiles* also applied to narrow passages, guarded on each side by mountains, &c.

To *DEFILE*, to go off file by file. See *FIRE*.

The army began to *defile* on the left, and was forced to *defile* on each end of the field, on account of the marauds, and the woods.

DEFINITE, in *Grammar*, is applied to an *ARTICLE* that has a precise, determinate signification.

Such are, the article *le* in Latin, *le* and *le* in French, &c. which fix and ascertain the noun they belong to, to some particular; as, *the King*, *the boy*; whereas, in the quality of *king*, *boy*, the articles *le*, and *le*, mark nothing precise; and are therefore called *indefinite*.

DEFINITION, in *Logic*, an enumeration of the chief simple ideas, whereof a compound idea consists; in order to ascertain, or explain, its nature and character.

The schoolmen give very imperfect notions of *definition*. Some define it the first notion, or conception, that arises of a thing, whereby it is distinguished from every other, and from which all the other things, that we conceive of it, are deduced; but the usual definition of it is *ratio generis et differentie*, a discourse explaining what a thing is; that is, as some farther explain it, a discourse setting forth those attributes which circumscribe and determine the nature of a thing. For to explain, is only to propose the parts separately, and expressly, which were before proposed conjunctly and implicitly; so that every explanation has regard to some whole. Hence, according to the diverse kinds of parts in any thing, viz. physical parts, metaphysical parts, &c. arise so many different kinds of *definitiones* of the same thing: thus, man is either *defined* an animal, consisting of soul and body; or, a reasonable animal, &c.

Definitiones are of two kinds, the one *nominal*, or, of the name; the other *real*, or, of the thing.

DEFINITION of the name, or *nominal DEFINITION*, is that which explains the sense or signification appropriated to a word; or, as Wolfius more accurately considers it, it is an enumeration of certain marks, or characters, sufficient

ficient to distinguish the thing *defined* from any other thing; so as to leave it out of doubt, what the subject is that is intended, or denoted by the name. This is what is meant by *definition* in mathematics.

Such is the *definition* of a figure, when it is said to be a quadrilateral, equilateral, rectangular figure.

By *definition of the name*, is either meant a declaration of the ideas and characters appropriated to the word in the common usage of the language; or the peculiar ideas, &c. which the speaker thinks fit to denote by that word, i. e. the special sense wherein he proposes to use it, in his future discourse. For it may be observed, that the significance of any word depends entirely on our will; and we may mix what idea we please to a found, which itself signifies nothing at all.

The *definition* of the name, therefore, in the second sense, is merely arbitrary, and ought never to be called in question; only it is to be minded, that we keep invariably to the same signification. Hence, a *definition* comes to stand, or to be made use of, as an undoubted, or self-evident maxim; as it frequently does, and particularly among geometers, who, above all other people, make use of such *definitions*.

Not that we mean, that after having *defined* a thing to be so, there is nothing in our idea added to the *defined* term; but must be granted to the thing itself; thus, if any one should *define* heat to be a quality in certain bodies, like that which we feel upon the application of fire, or hot bodies; it no man could hold fault with the *definition*, as far as it expresses what he means by the word heat; but this does not hinder us from deriving, that there is any thing in the body that warms us, like what we feel in ourselves.

DEFINITION of the thing, or real DEFINITION, is properly an enumeration of the principal attributes of a thing, in order to convey or explain its nature.

Thus, a circle is *defined* a figure, whose circumference is every where equidistant from its centre.

Wallius *defines* a real *definition* to be a distinct notion explaining the perfections of a thing; that is, the manner wherein the thing is made, or done: such is that of a circle, whereby it is said to be formed by the motion of a right line round a fixed point. On which footing, what was before intimated as a *real definition* of a circle, amounts to no more than a nominal one.

This notion of a *real definition* is very strict and just; and affords a full and distinct notion of a *real* and a *nominal* one. But though it has the advantages of analogy, distinctness, and convenience, on its side; yet, being only itself a *nominal definition*, i. e. a *definition* of the term *definition*, we must consider it in this light, that is, as an idea fixed arbitrarily to that word, and which, the author always denotes by that word in the course of his book. But, in effect, it is not the usual sense, or acceptation of the term; which is much less convenient and distinct. And it is to that usual acceptation, we are here chiefly to have regard.

Definitions are also divided into *accurate* and *inaccurate*; the first make what we strictly call a *definition*; the second, we distinguish under the name of *descriptions*.

Of the parts enumerated in a *definition*, some are common to other things beside the thing *defined*; others are peculiar thereto: the first are called the *genus*, or *kind*; and the second, the *difference*. Thus, in the former *definition* of a circle, by a figure whose circumference is every where equidistant from its centre, the word *figure* is the *kind*, as being a name common to all other figures, as well as the circle: the rest are the *difference*, which specify, or distinguish this figure from every other figure. And hence arises that rule of P. de Cholusia, for the making of a *definition*. "Take, first, be something that is common to the thing *defined* with other things, and add to it something that is proper, or peculiar to the thing; i. e. join the genus and specific difference; and you will have a *definition*." "Think, e. g. *circle* is *defined* the art of speaking well; for that it is an art, is common to it with several other things; but that it is the art of speaking well, is peculiar to it alone."

There are five common rules of a good *definition*. 1. That it be clear, and more easy and obvious than the thing *defined*. 2. That it be universal, or adequate to the thing *defined*; that is, it must agree to all the species or individuals included under the same idea. 3. That it be proper or peculiar to the thing *defined*. The two ordinary defects of *definitions* are, not to agree either to the whole thing, or in the sole thing *defined*; *ex parte* and *ex parte*, than which nothing is more common, even among the best and justest authors. 4. That it be short. And 5. That neither the thing *defined*, nor a more frequent, more name, make any part of the *definition*.

Isid. Baeon observes on Aristotle's *definition* in the general, that they are very much like that, whereby men should be *defined* an animal that tills the ground. Nor

was his master Plato less exceptionable. The joke put upon him on that account is famous; Plato, it seems, had *defined* man, animal biped *terrestrial*, a two-footed animal without feathers. Upon which, Diogenes the Cynic, a great decider of the Academics, threw a cock stripped of his feathers, and quite naked, into the middle of Plato's school, crying, "Here is Plato's man."

Our *definition* of substance, it must be added, are very defective; and as for individuals, we have no *definition* at all. The ideas of substances are compounds of the various simple ideas jointly imposed, when they please themselves; and all we can do to *define* them, is only to enumerate those several simple ideas, as colour, density, malleability, weight, &c. Thus, gold is *defined* by such a peculiar colour, gravity, &c. Yet such *definitions* may raise an idea clear enough of that substance in the mind of one who is separately conceived, by his senses, all the simple ideas that are in the composition of the compound idea; *abstract* though the simple nature and efficient substance are unknown, and consequently cannot be *defined*.

It follows, therefore, that the modes, or attributes, that can be explained by what we properly call a *definition*.

DEFINITION, in Rhetoric, is one of the common places, and is defined by Tully, a short comprehensive explanation of a thing.

The *definition* of the orator, it must be observed, differs much from those of the logician and philosopher: the latter *define* a thing closely and strictly by genus and difference; e. g. man is a reasonable animal, &c.

The orator takes a larger compass, and *describes* things more ornamentally from the places of rhetoric, thus: man is a curious work of an Almighty Creator, framed after his own image, endued with reason, and born for immortality. But this rhetorical *definition*, in strictness, comes nearer to the nature of a description, than an accurate *definition*.

DEFINITIVE is applied to somewhat that terminates, or denies a question, or proceeds. Thus we say,

The house of lords have passed a *definitive* sentence in such a case: the church has given a *definitive* judgment on such an article of faith.

The word stands in opposition to *propositional*, and *interlocutory*.

DEFINITIVE phrase, in Grammar. See DEMONSTRATIVE.

DEFINITIONS, in Grammar, denote according to the arrangement of Mr. Harris, one of the four species of words; or such as are significant by relation, called by others ARTICLES.

DEFINITOR, a term used in several religious orders, for an officer, or counsellor of a general, or superior, in certain monasteries.

In most orders of religious, the *definitors* take place after the superior of the convent he lives in, when in the convent itself; but out of the convent, the *definitors* place is before his own superior.

Definitors are also subject, in the convent they reside in, to the immediate superior of the convent, as to things relating to the monastic discipline, but in nothing else.

DEFLAMMATION, in Chemistry, the kindling, or setting fire to a salt, a mineral, or other matter, either alone, or mixed for that purpose, with a sulphureous one, in order to purify it. As is done in the preparing of Ethiops mineral by fire, see ETHIOPS.

The word is formed of the Latin *de*, and *flamma*, to burn. This last process has been often recommended to the world as of great use in trying the strength of brandy, and other vinous liquors, and has been greatly improved and improved by Mr. Geofroy.

The common way of trying brandy by *deflammation*, is to measure out any quantity of it, then to heat it in a let it on fire; if it burns no longer than the remainder is half as much as the quantity measured out of the real was, then the spirit itself is found to consist of half water, and half nearly inflammable spirit; that is, it is exactly what we understand by the term perfect proof, and according as the remainder is more or less than half the original quantity, it is so much below or so much above proof, or the due strength of brandy.

This method is much more certain than that by the crown of bubbles, which arises upon distilling the spirit in a still. Mr. Geofroy's method is thus: take a cylinder vessel two inches high, and as much in diameter, consisting of thin plate silver, that metal being much less liable to rust than copper; this vessel must be fitted with a little rectangular piece exactly graduated into lines, half lines, &c. then the vessel being set level upon a copper case made to contain it, a quantity of the brandy to be examined is poured in, to the height of fifteen lines. This height is to be exactly hit by pouring in more than enough at first, and then with a small tube sucking out what is superfluous; then the vessel being heated a little, so as just to make the liquor

liquor fumes, it is to be set on fire, and left to go out of itself. At the instant when the flame expires the gage is plunged perpendicularly into the vessel, and the lines and quarters exactly noted, which the liquor wants of its former height: this difference gives the precise quantity of pure spirit, or alcohol, originally contained in the liquor. *Mém. Acad. Paris 1718.*

DEFLECTION, the turning any thing aside from its former course, by some adventitious or external cause.

The word is often applied to the tendency of a ship from her true course, by reason of currents, &c. which divert her, and turn her out of her right way.

DEFLECTION of the rays of light, is a property which Dr. Hooke observed in 1674-5, and read an account of before the Royal Society, March 18, the same year. He says, he found it different both from refraction, and reflection; and that it was made towards the surface of the opaque body perpendicularly.

This is the same property which Sir Isaac Newton calls *refractions*. It is called by others *refraction*.

DEFORATION, or **DEFORMITY**, the act of violating, or taking away a woman's virginity.

Death, or marriage, are deemed by the civil law in case of *deforation*. Many anatomists make the hyena a real proof of virginity, persuaded that where it is not found, the girl must have been *deforiated*. See *HYENA*.

The ancients had no much respect for virginity, that they would not put them to death, till they had first procured them to be *deforiated*. On the contrary, the natives of the coast of Malabar hold virginity in little estimation, that they pay trangers to come and *deforiate* their brides. Among the Scots, it was a privilege of the lords of the manor, that they should have the first night's lodging with their tenant's wives. King Malcolm III. allowed the tenants to redeem this service at a certain rate, called *Marriage*, consisting of a certain number of cows. Buchanan says, it was redeemed with half a mark of silver. The same custom had place also in Wales, Flanders, Friesland, and some parts of Germany. See *SCOTLAND*, *ENGLAND*.

By the custom of Anjou and Maine, a maid, after twenty-five years of age, may suffer herself to be *deforiated*, without being dishonoured for it by her father.

De-Casse quotes an arrest of the nineteenth of March, 1400, obtained by the inhabitants of Abbeville, against the bishop of Amiens, for taking money to dispense with an injunction he had made, not to suffer them to consummate their marriage the third first night; the injunction being founded on a canon of the fourth council of Carthage, which decrees the same, out of reverence of the matrimonial benediction.

DEFLUVIUM, is used to express a distemper in trees, whereby they lose their bark: it is thought to be caused by a sharp humour, that dissolves the pith whereby the bark is fastened to the wood; and sometimes by too much drought.

DEFLUXION, or **FLOODING**, a falling, or flowing of some humour to any part of the body; as of them on the trachea, and membranes, in a cough.

The word is formed from the Latin *desco*, I flow down, the humours falling upon some part, where they are gathered together.

Defluxion on the lungs are of dangerous consequence. See *CATARHUS*, and *PHTHISIS*.

Defluxion on the eyes produce a weakness of sight, and frequently blindness. See *EXUS*.

DEFORCEMENT, in *Law*, a with-holding lands, or tenements, by force, from the right owner.

DEFORCEMENT, in the law of Scotland, is used for the resisting, or offering violence to the officers of the law, while they are actually employed in the exercise of their functions; by putting its orders and sentences in execution; whether they be officers of the supreme courts of justice, as sheriffs, pursuivants, messengers, mace-bearers; or of inferior courts, as mayors.

The punishment of this crime is confiscation of moveables, joined with some arbitrary punishment; as fine, imprisonment, banishment, or corporal pains, according to the degrees of violence, and other circumstances which aggravate the crime; besides, the party aggrieved may have an action of damages, to be highly taxed out of the fine and reward of the offender's effector, or other effect. See *ROYAL CRIMINAL LAW*.

Deforcers of officers of the custom-house, is provided against by the same statutes in England.

DEFORCEOR, or **DEFORCIANT**, one that calls out another from his lands, or tenements, by more force.

Deforcer differs from *difficer*, in that a man may *difficer* another without force; and that a man may *deforce* another who never was in possession; as where several persons have a right to lands, as common heirs, and one entering first keeps out the rest. See *DISSEIZIN*.

Deforcer also differs from *intruder*, in that a man becomes *intruder* by a wrongful entry only into lands void of a possessor; whereas a *deforcer* holds out the rightful heir. See *INTRUSION*.

DEFORMITY is immediately opposed to **BEAUTY**, and denotes the want of that uniformity, symmetry, and variety, necessary to constitute beauty. Accordingly, Dr. Housheon defines it by the absence of beauty, or a deficiency in the beauty expected in any species. *Deformity* and beauty may be considered either as natural or moral. These are both referred by the above mentioned ingenious writer to an internal cause, and our perceptions of them, as he supposes, arise from an original arbitrary structure of our own minds, by which certain objects, when observed, are rendered the occasions of certain sensations and affections.

That many objects give no pleasure to our senses is obvious. Many are certainly objects of beauty; but then, says the author, there is no form which seems necessarily disagreeable or useful, when we dread no other evil from it, and compare it with nothing better of the kind. Many objects are naturally disagreeing, and distasteful to our external senses, as well as others pleasing and agreeable; as smells, tastes, and some separate sounds; but with regard to our sense of beauty, no composition of objects which give not unpleasant simple ideas, seems positively unpleasant, or painful of itself, but we never observed any thing better of the same kind.

Had there been a species of the form which we now denominate ugly, or *deformed*, and had we never seen or expected greater beauty, we should have received no disgust from it though the pleasure would not have been so great in this form as in those we now admire. Our sense of beauty seems designed to give us positive pleasure; but not positive pain, or disgust, any farther than what arises from disappointment.

There are, indeed, many faces which, at first view, are apt to cause dislike. But this is generally not from any positive deformity, but either from want of expected beauty, or from the carrying some natural indications of morally bad dispositions, which we all acquire a faculty of discerning in countenances, airs, and gestures. That this is not occasioned by any form positively disgusting, appears hence, that if upon long acquaintance we are apt of finding sweetness of temper, humanity, and cheerfulness, though the bodily form continues, it shall give us no disgust. There are horrors raised by some objects, which are only the effect of fear for ourselves, or compassion towards others, when either reason, or some foolish association of ideas, makes us apprehend danger, and not the effect of any thing in the form itself. For we find, that most of those objects, which excite horror at first, when experience, or reason, has removed the fear, may become the occasion of pleasure.

The casual conjunction of ideas gives us disgust, where there is nothing disagreeable in the form itself. And this, in effect, is the cause of most of our fantastical aversions to the figures of deformed animals, &c. Thus serpents of all kinds, and many insects, really beautiful enough, are beheld with aversion by many people, who have got some accidental ideas of mischief associated to them. A similar reasoning is applied to our perception of moral beauty and deformity. Inquiry into the Original of our Ideas of Beauty and Virtue, p. 106.

But it is more just to distinguish between the sentiments of delight or disgust, excited in us by beautiful or deformed objects, which are effects of some cause, and the natural and real qualities of the perceived objects by which they are produced. There are objects, says an excellent writer, which have a natural aptitude to please or offend, or between which and the contemplating mind there is a necessary congruity or incongruity; and though the actual perception of the understanding, and consequent feeling of the heart, in contemplating the actions and affections of moral agents may exist in very different degrees, on account of the incidental obstructions arising from bodily indisposition, mental prejudices and biases, and the association of ideas; yet, to every rational mind properly disposed, morally good actions must for ever be acceptable, and can never of themselves offend; and morally evil actions must for ever be disagreeable, and can never of themselves please. What is right in actions and characters is beautiful and amiable, and gives pleasure; what is wrong is deformed and odious, and excites disgust: right and pleasure, wrong and pain, are as distinct as cause and effect. It is no less absurd to maintain, that the perception of virtue is nothing distinct from the reception of the pleasure resulting from it, than to infer, with some metaphysicians, that solidity, extension, and figure, are only particular modes of sensation, because attended, whenever they are perceived, with some sensation of sight or touch. Thus does this

author shew, that moral beauty and deformity are real qualities of certain actions; in which consists their aptitude to please or disgust. With respect to natural beauty, he observes, that uniformity amidst variety pleases, because of the *nature* of variety and uniformity, which are such, that whenever united, they are adapted to please every free, unbiased mind, that discerns them. He accounts for the pleasure they afford, without referring them to an arbitrary, internal sense, by the following circumstances that attend them. They are more easily comprehended by the mind: order and symmetry give things their stability and strength, and subservient to any valuable purpose; regularity and order evidence art and design. Disorder and confusion, whence deformity arises, denote only the privation of regularity and order; or any arrangement and disposition of things, which are not according to a law, rule, or plan, and more not design. There are not so many dissembling, except where we previously expected order, or where impotence or want of skill appear, and the contriver has either failed of his design, or executed it ill. See on this subject Dr. Price's Review of the principal Questions and Difficulties in Morals, ch. ii. p. 100. See an admirable Essay on bodily Deformity, by Mr. Hay, in the Fugitive Pieces, vol. i. p. 43, &c.

DEPOSITION, *Deposito*, the punishment of burning alive, instituted, among the Romans, on Vestal virgins guilty of incontinency. It is also a custom among the Hungarians to inflict this punishment on women convicted of adultery. Heretics also were punished in this manner. See **HERESY**.

DEFT ARDAR, or **DEFTERDAR**, the treasurer of the revenues of the Turkish empire. See **TREASURER**. The word is compound, first, of *deft*, a Turkish name for a book, register, inventory, &c. which Meninski derives from the Greek *deftes*, the skin or parchment anciently wrote on. The second word, whereof *deftardar* is compounded, is *dar*, a Turkish and Persian word, signifying *treasury*, or *treasure*, &c. d. book-keeper of the money received and expended.

Meninski calls him *deftes daruvarian*, *deftes daruvar*, and *daruvar daruvar*, *daruvar daruvar*. Calaneo makes him the keeper, and compeller of the books of receipts and payments. The *deftardar*, or *deftardar* calls him, *deftardar*, has in his charge the rolls and accounts of the militia, and the treasury; he receives all the grand vizier's revenues, pays his taxes, and furnishes the expenses of all public affairs; in which his office differs from that of the chamberlain, who is treasurer of the seraglio or court, as the *deftardar* is of the state.

Recent makes a *deftardar*, whom he calls *deftardar*, in each beylerbeglic, or government. Vigoretti affirms us, there are but two, the one for Europe, and the other for Asia; the first resides at Constantinople, and has under him two general commissaries, or deputies, one for Hungary, Transylvania, Wallachia, Croatia, Servia, Bulgaria, Bosnia, &c. the other for Greece and the Morea, with the islands of the Archipelago. Each of these has under him as many sub-commissaries, or agents, as there are sanjacks in his province; which sub-commissaries have as many clerks as there are sanjacks in their sanjacks, to keep the account of the finances in their districts. The *deftardar* of Asia has two general deputies, the one for Anatolia, the other for Syria, Arabia, and Egypt; these have likewise their sub-agents, clerks, &c. as those of Europe.

DEGENERATION, the act of failing, or declining from a more perfect, or valuable kind, state, or condition, to an inferior or worse.

It is a great dispute among the naturalists, whether or no animals, plants, &c. be capable of degenerating into other species? The affirmative is urged by many, as a strong objection against the plant being consumed in the food, and that doctrine of generation wherein that is supposed to be the case. But our best and best naturalists maintain the opinion of such a *degeneration*, or *transmutation*, to be erroneous, and a chimera; not but they allow, that a plant, by being transplanted to an improper soil, or time, may be depraved, as a Dutch rose of an hundred leaves, may only produce another rose, for flout thereof in number of leaves, colour, smell, &c. Such a *degeneration* is possible, and frequently happens; but a species transformation seems out of the power of nature; a new form ever supplanting a new *generation*, which again supposes a corruption of the former kind.

DEGLUTITION, in *Medicine*, the act of swallowing the food. *Deglutition* is performed, in the first place, by means of the tongue, driving the aliment into the oesophagus, or gul-

let; and then, by the contraction of the sphincter, and the fleshy fibres of the same oesophagus, which, lessening the bore, or aperture thereof, protrude the contents downwards into the stomach, in our eating. *Deglutition* succeeds *mastication*, and is followed by *excretion*.

A difficulty of swallowing may be occasioned by a swelling of the oesophagus, by a ferocious bronchitis, by a thickening of the mucus in the oesophagus, by indurations of the oesophagus, by a fungus in it, by a scirrhous fungus, by some hard substance lodged in it, and occasioned by roots, and by hyaline.

Dr. Duncan, in his Medical Cases, 1778, mentions the case of a difficult *deglutition*, supposed to arise from a venereal infection, in which electrical sparks, applied to the fauces, were of considerable service, and by degrees removed the complaint.

DEGRADATION, in our law-books called *degradation*, and *degradation*, the act of depriving, or stripping a person for ever of a dignity, or degree of honour; and taking away the title, badge, and privileges thereof.

The *degradation* of a peer, a priest, a knight, a gentleman, in office, &c. are performed with diverse ceremonies. That which anciently obtained in *degrading* a person from his nobility, is very curious. It was practised in the time of Francis I. upon captain Fagel, who had in a cowardly manner given up Bourdeaux, whereof he was governor.

On this occasion, twenty or thirty cavaliers, without helmets or reproach, were assembled; before whom the gentleman was accused of treason, and breach of faith, by a king at arms. Two scaffolds were erected; the one for the judges, heralds, and pursuivants; and the other for the guilty cavalier, who sat armed at all points, and his shield placed on a stake before him, reversed with the point upwards. On his side stood twelve priests, in surplices, who sung the rights of the dead. At the close of each psalm they made a pause, during which the officers of arms stripped the condemned of some piece of his armour, beginning with the helmet, and proceeding thus, till he was quite naked; which done, they broke his shield in three pieces with a hammer. Then the king at arms exposed a basin of hot water on the criminal's head; and the judges, putting on mourning habits, went to the scaffold. This done, the *degraded* was drawn from off the scaffold, with a rope tied under his armpits, laid on a bier, and covered with mournful cloaths; the priest singing some of the prayers for the dead; and then he was delivered to the civil judge, and the executioners of justice.

For a more sensible instance, Sir Andrew Harel, earl of Carlisle, being attainted and convicted of treason, 18 Edw. II. seven years after judgment was pronounced on him, his head was broken over his head, and his spurs hewn off his heels; Sir Anthony Lucy, the judge, laying to him, "Andrew, now sit down on knighthood, but a knight." By stat. 13 Car. II. William lord Monson, Sir Henry Mildmay, and others, were *degraded* from all titles of honour, dignities, and preeminences, and prohibited to bear, or use, the title of lord, knight, esquire, or gentleman, or any sort of arms, for ever afterwards.

It has been maintained that the king may *degrade* a peer; but it appears from later authority, that he cannot be *degraded* but by act of parliament.

As to ecclesiastics, we have an instance of *degradation* before condemnation to death, in the eighth century, at Constantinople. It is in the prison of the patriarch Constantine, when Constantine Capasymus failed to be executed. He was made to attend the altar, and the patriarch Nicetas sent some of his bishops to strip him of the pallium, and anathematized him; then they made him go out of the church back wards.

But we have a much later instance in our own history; when Cranmer, archbishop of Canterbury, was *degraded* by order of queen Mary; they dressed him in episcopal robes, and a staff of corn, put the mitre on his head, and the pastoral staff in his hand; and in this attire, they led him to the people. Which done, they stripped him again, and he died.

At present, they do not stand so much on the ceremony of *degradation*, in order to the putting a priest to death; by reason of the delays and difficulties that it would occasion. Pope Boniface pronounced, that six bishops were required to *degrade* a priest; but the difficulty of assembling in many bishops, rendered the punishment frequently impracticable.

With us, a priest, after having been delivered to his ordinary, if he cannot purge himself of the crime laid at his door, has his gown, and other robes, stripped over his ears by the common hangman; by which he is declared divested of his orders.

It is decided, however, that *degradation* does not efface the prickly character.

Degradation only forms to differ from *deposition* in a few ignominious ceremonies, which custom has added thereto. Accordingly, in the banquet of Arras, archbishop of Rheims, sentenced in the council of Orleans, in 1521, it was deliberated, what form they should follow in the deposition; whether that of the canon, that is, simple deposition; or that of custom, viz. *degradation*. And it was declared, that he should surrender the ring, pastoral staff, and pallium; but that his robes should not be torn off.

In effect, the canon prescribes no more than a mere reading of the sentence. It is the rest, therefore, added thereto by custom, viz. the stripping of the ornaments, and the tearing the pontifical vestments, that properly constitutes *degradation*.

DEGRADATION, in *Painting*, expresses the blurring and rendering dim and confused the appearance of distant objects in a landscape, so that they shall appear there, as they would do to an eye placed at that distance from them. See *Perspective*.

DEGRADED, in *Heraldry*. A cross *degraded*, is a cross marked, or divided into three at each end, diminishing as they ascend towards the middle, or centre; by the French called *croix en sautoir*. See *Cross*.

DEGREES, in *Astronomy*, is used in speaking of equinoxes. It is the index as the highest power in the unknown quantity is 25, it is of the second degree, &c.

DEGREE *of Arc*, in *Geometry*. See *Line* and *Measure*.

DEGREE, in *Geometry*, is one of a circle, including a three hundred and sixtieth part thereof.

Every circle, great and small, is supposed to be divided into 360 parts, called *degrees*: the *degree* is subdivided into lesser parts, called *minutes*: the minute into 60 others, called *seconds*: the second into 60 thirds, &c. It follows, that the *degrees*, minutes, &c. of greater circles are greater than those of less.

The subdivisions of *degrees* are fractions, whose denominations proceed in a sexagesimal ratio; that is, a first minute is $\frac{1}{60}$, a second $\frac{1}{3600}$, a third $\frac{1}{216000}$, &c. But these denominations being troublesome, their logarithms are substituted in common use, as indices thereof. Thus a *degree*, as being the integer, or unit, is denoted by 0, a first minute, or prime, by 1; a second by 2, or 2', a third by 3, or 3', &c. Accordingly, 3 *degrees* 25 minutes, 16 thirds, are written 3° 25' 16".

But though the ancient Egyptians, to whom this division is usually ascribed, did, by means thereof, free astronomical calculations from fractions; their fractional fractions may be named as integers; and were very happy in the choice of such a number of *degrees* in the circle, as admitted of a just division, by 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 16, 20, 24, 30, 36, 45, 60, 72, 90, 108, 144, 180, 216, 270, 324, 360, &c. with good reason, with the sexagesimal fraction for alides, and decimals taken in their room; or that the degree were subdivided into 100 equal parts, and each of their again into 100, &c. For in decimals there is no occasion for reducing lesser fractions into greater, or greater into lesser; which is a tedious article in fractions. Stevinus even holds, that this division of the circle which he contends for, obtained in the wise age, in *scintilla sapientie*. See *Line*, *Colony*, lib. 1. def. 6.

The magnitude or quantity of angles is accounted in *degrees*; because the curvature of the circle being uniform in all its parts, equal angles at the centre are subtended by equal arcs, and by similar arcs in peripheries of different diameters. Thus we say, an angle of 90 *degrees*, of 30 *degrees* 30 minutes, of 45 *degrees* 15 minutes 45 seconds.

Such a star is supposed to many *degrees* above the horizon, or descends to many *degrees* from the equator.

Such a town is situate in so many *degrees* of longitude and latitude.

A sign includes 30 *degrees* of the zodiac.

DEGREE *of Latitude* is, on the supposition of the sphericity of the earth, the sixth part of the meridian; or more generally, it is that space through which an observer must move on the meridian, in order to increase or diminish the distance of a star from the zenith by one *degree*. See *Latitude*.

The quantity of a *degree* of a meridian, or other great circle, on the surface of the earth, is variously determined by various observers: the methods too made use of are various. See *Earth*.

Ptolemy fixes the *degree* at 68; Arabic miles, accounting 72 fadl to a mile. The Arabians themselves, who made an exact computation of the diameter of the earth, by measuring the distance of two places under the same meridian, in the plains of Sena, by order of Almanon, only make 50 miles. Kepler, determining the semidiameter of the earth by the distance of two mountains,

Vol. II. N° 92.

makes a *degree* 13 German miles; but his method is far from being accurate. Sorbicus, taking the diameter of the earth, from the distance of two parishes of the equator, finds the quantity of a *degree*, by one method, to be 57064 Paris toises, or 34234 feet; and by another method, 57275 toises, or 34325 feet. The mean between which two numbers, M. Picard found by actual survey, in 1669, from Amiens to Melun, the most sure, as it makes the quantity of a *degree* 57060 toises, or 34230 feet, which reduced to other measures, gives the quantity of a *degree* of a great circle, in

English miles of 5280 feet each,	69.173
French miles of 4000 toises each,	62.5
Common French toises of 2221 toises 35	
Rhine land perches of 18 feet,	35.550

However M. Cassini, at the command of the King of France, in the year 1700, repeated the same labour, and measuring the space of 6 *degrees* 48 minutes, from the observatory at Paris, along the meridian to the city of Collioure in Roussillon, that the extremes of the interval might diminish the error, found the quantity of a *degree* to be 57060 toises, or 34234 feet; but, amounting to 305160 English feet. On which finding, the quantity of a minute of a *degree* of a great circle of the earth is 5710 Paris feet, and that of a second, 65 feet.

With which account pretty nearly agrees that of our countryman Mr. Narborough, who, about the year 1665, measured the distance between London and York, and found it 200721 English feet; and finding the distance of latitudes 28° 28', determined the quantity of one *degree* to be 307160 English feet, or 57120 Paris toises, or 34234 English miles, 188 yards. See *North*, *Pilot*, *Phil. Nat. Math.*, lib. prop. 19, and *Hist. Acad. R. Science*, anno 1700, p. 153.

M. Cassini, the son, completed the work of measuring the whole arc of the meridian through France in 1727. For this purpose he divided the meridian of France into two arcs, which he measured separately. The one from Paris to Collioure had given him 57077 toises in a *degree*; the other from Paris to Dunkirk 57060; and the whole arc from Dunkirk to Collioure 57066, the same as M. Picard's. M. Mouton, in 1700, intending to correct the error of Sorbicus, found by astronomical observations, that the *degree* between Amiens and Bergues contained 57033 toises. Messrs. Marignier, Clairaut, Cagnat, le Monnier, and Outhier de France, were deputed on a northern expedition, and began their operations, assisted by M. Cassini, at an ancient altar of Sweden, in Swedish Lapland, in July, 1736, and continued them by the end of the following year. They obtained the measure of a *degree*, the middle point of which was in lat. 66° 22' N. and found it to be 57470 toises, when reduced to the level of the sea. Another company of gentlemen was about the same time ordered to the south, viz. Messrs. Cassin, Bouguer, and La Caille, to whom were joined Don Jorge Juan, and Don Antonio de Ulloa of Spain. They left Europe in 1735, and began their operations in the province of Oqule in Peru, about October, 1736, and finished them after many interruptions, about eight years after. The Spanish gentlemen published a separate statement, and assign for the measure of a *degree* of the meridian at the equator 57073 toises. M. Bouguer makes it 56955 toises, when reduced to the level of the sea; and M. de la Caille, being at the Cape of Good Hope in 1732, found the length of a *degree* of the meridian in latitude 33° 45' 25" to be 57073 toises. In 1755, Father Boscovich found the length of a *degree* in latitude 43° 20' to be 56924 toises, as measured between Rome and Rimini, in Italy. In the year 1746, M. de la Caille and de la Caille again examined the former *degree* in France, and, after making all the necessary corrections, found the measure of a *degree*, the middle of which is in 49° 22' N. to be 57074 toises; and in the latitude of 43° 20' to be 56930 toises. From these measures it appears that the earth is not a sphere, but an oblate spheroid. See *Figure of the Earth*. See Marignier's *Figure of the Earth*, &c. 3vo. 1738.

The method of measuring a *degree* of the terrestrial meridian is to measure a certain distance upon it by a series of triangles, whose angles may be measured by actual observation, connected with a baily whole length may be taken by an actual survey, and then to observe the different altitudes of the same star at the two extremities of that distance. By this means the length of the arc may be compared with its amplitude, or the number of minutes and seconds which it contains.

DEGREE of Longitude, is the space between two meridians;

D E G

the quantity of which is variable according to the latitude.

These expressions are borrowed from the ancients, who were acquainted with a very large extent of earth, from east to west, which they estimated the length, and as much less from north to south, which passed with them for the breadth, of the earth. See LONGITUDE.

The quantity of a *degree* of a great Circle, when the distance of any other parallel from the equator, being given, the quantity of a *degree* in that parallel is found by this canon, as the whole sine, or radius, is to the cosine of the distance of the parallel from the equator; so is the quantity of a *degree* of the equator to the quantity of a *degree* of the parallel.

Log of whole line. 10 per cent.

We say, the second degree, the third degree, Gregory the

DEG

deny the immortality of human souls, alledging that men perish at death, and that the present life is the whole of human existence. 4. Those who believe the existence, perfection, and providence of God, the obligation of natural religion, and a state of future retribution, on the evidence of the light of nature, without a divine revelation. Such as these, he says, are the only true *Deists*, but their principles, as unreasonably, should lead them to embrace Christianity; and therefore he concludes, that there is now no conflict between some of *Deism* in the world. Evidence of Nat. and Rev. Religion, p. 12, 27.

The first *Deist* whose name was then known in this country, was Henry Baron of Chichester. He lived and wrote in the last century. His book *De Veritate* was first published in Paris in 1622. This, together with his book *De Causa Eternitatis*, of his *Traité de Religion Naturelle*, were afterwards published in London. His celebrated work *De Religionis Gentilium*, was published at Amsterdam in 1669, in six vols. and in 1700, in five and an English translation of it was published at London in 1705.

As he was one of the first that formed *Deism* into a system, and inserted the immensity, universality, and absolute perfection of natural religion, with a view to discredit all extraordinary revelation, as miracles and oracles, we shall subjoin the five fundamental articles of this system of religion. They are these: 1. That there is one Supreme God. 2. That he is chiefly to be worshipped. 3. That piety and virtue are the principal part of his worship. 4. That we must repent of our sins, and if we do so, God will pardon them. 5. That there are rewards for good men, and punishments for bad men, both here and hereafter. Our own age has produced a number of advocates in the same cause; and however they may have differed among themselves, they have been agreed in their attempts at illustrating the evidence and authority of divine revelation. We might mention Hobbes, Blount, Toland, Collins, Woolston, Tindal, Morgan, Chaub, Lord Bolingbroke, Hume, &c. Some have also added Lord Shaftsbury to the numbers.

But the spirit of Christianity bore no reason to regret the free and unobscured illustration which their religion has undergone. Objections have been raised and urged in its full force, and it fully answered; arguments and railings have been replied to, and the controversy between Christians and *Deists* has called forth a great number of excellent writers, who have illustrated both the doctrines and evidence of Christianity in a manner that will ever reflect honour on their names, and be of lasting service to the cause of genuine religion, and the best interests of mankind.

The number of *Deists* is said to be daily increasing: in England, many men of speculation and letters are said to incline that way; and the like is observed in some of our neighbouring nations, where freedom of speaking, writing, and thinking, are indulged. Not that unrestrained liberty in this respect can ever injure Christianity, or serve the cause of *Deism*: truth neither needs nor fears disguise; but where freedom is allowed, men's sentiments on the subject of religion, are more generally known.

DEITY, Godhead, a common appellation given to God; and also by the poets to the heathen gods and goddesses.

DEIVIRILE, a term in the school theology, signifying something divine and human at the same time. See **THEANDRIC**.

The word is a compound of *Dei*, God, and *virilis*, of vir, man.

DELEGATES, certain persons *deputed*, or appointed by the king's commission, under the great seal, to sit upon an appeal to the king in the court of chancery. See **COURT OF DELEGATES**.

DELEGATION, a commission extraordinary given a judge to take cognizance of, and determine some cause, which ordinarily does not come before him.

In the civil law, *delegation* also denotes a sort of surrogacy, whereby a person delivers another before in his place. See **Ulpian**. l. 1. *de deo et actionibus et delegationibus*.

This *delegation* differs from transferring, or translation, because three persons intervene in a *delegation*, viz. the creditor, the debtor, and a third, who himself is indebted to the debtor, and on whom the creditor transfers the obligation he was under to pay the creditor, *delegating* him, as it were, for this purpose. But, in a simple transfer, it is enough the transferor and the transferee be present.

DELETERIOUS, from *deleo*, *deleo*, *deleo*, to destroy, as some times used among naturalists, for such things as are of a pernicious and poisonous nature. See **POISON**.

DELE, a quarry, or mine, where there is coal or dug.

From the Saxons word *dele*, *dele*, *dele*, or *dele*.

DELE, or *drive*, *dele*, is also a certain quantity, dug out of a mine, see **COAL**.

DELE is also used in *Horology*, for one of the stones or of temper; being a square in the middle of the clock chisel.

A *dele* term was anciently due to him who receded from his own challenge, or any was separated from his party or word. If there be two, or more *dele*, in an action, then it is then no longer an abatement, it is *dele*, if it be of matter, or charged upon it then becomes a charge of parties bearing.

DELE, a kind of pottery of baked earth, covered with an enamel, or white glazing, which gives it the appearance and nearness of porcelain. The base of this pottery is clay, and the kind of clay chiefly used are the blue and green, with an addition of marble or sand, in order to lessen the contraction of the clay, in firing; less compact, and to insert a better ground for the enamel. Red clay is also used, which, on account of its ferruginous matter, binds and gives a greater solidity.

The proportions of these ingredients vary in different works, according to the different qualities of the earth employed. Three parts of blue clay, two of the clay and five parts of marble, form the composition used in several manufactures. Vessels formed of these materials must be heated very gently, to avoid cracking. They are then to be placed in a furnace to receive a final baking, and they are fully to be covered with enamel or glazing, which is done by placing upon the vessels thus prepared, the enamel, which has been ground very fine and diluted with water. The glazing, which is remaining on the vessels, ought to be to be so as to show the ware underneath. The enamel of *dele* is composed of sand or finely grinding flint, calc of lead, and calc of tin. The vitrification of sand is effected by fusing it less than an equal part of alumine flint, or twice its weight, and calc of lead, and one part of calc of tin, which is designed for giving a white opaque colour to the ware, it is to be added in three or four parts of all the other ingredients taken together. Mr. D'Arcy recommends for the white enamel, used in glazing, a mixture of a hundred pounds of calc of lead with about a seventh part of that quantity of calc of tin for common *dele*, or a fourth part of calc of tin for the best *dele*, a hundred, or a hundred and two pounds of fine flint, and about twenty or thirty pounds of calc of tin, or calc of flint. To make this enamel, lead and tin are calcined together with a strong fire, or the lead is also to be made into a frit with the flint or silica. The whole, being well mixed and ground together, is placed under the furnace, where it is melted and vitrified during the baking of the ware. Then it is to be ground in a mill, and applied as above directed. *Dict. of Chem. Fr. edit. 1777. See ENAMEL, GLAZING, and PORCELAIN.*

DELEA, Delia, in *delphic*, a quinquennial festival in the island of Delos, instituted by Theseus in honour of Venus. *Fast. Antich. Græc. lib. ii. cap. 20.*

DELEA, in *delphic*, feasts celebrated by the Athenians, in honour of Apollo, furnished *Delia*. The principal ceremony in this feast, was an embassy, or rather a pilgrimage, to Apollo of Delos, performed every five years, by a certain number of citizens, deputed for this purpose, and called *Delia*, *Delia*, *Delia*, or *Delia*, *Delia*, &c. the *Delia*, and the first person of the embassy, or deputation, *Delia*, *Delia*, *Delia*. To him were added four more of the family of the *Delia*, jointly descended from Mercury, who reigned all the year at Delos, to assist in the temple. The whole deputation for not in five vessels, carrying with them every thing necessary for the feast, and the sacrifices.

The *Delia*, who went ahead, were crowned with laurel. At their arrival, they immediately offered a sacrifice to Apollo, and, after the sacrifice, a number of young men danced round the altar, a dance called in Greek *Pyrrhia*, wherein, by their various motions, and directions, they represented the turnings and windings of a labyrinth. When the *Delia* returned to Athens, the people went out to meet them, had received them with all the joy and acclamation imaginable. They in the first show their crown till their commission was fully completed, and then they consecrated it to him, and in his temple.

The whole time of their going and returning, with all the ceremonies of their embassy, was called the *Delia*, during which time, no criminal might be executed, which was a peculiar privilege of this feast, was allowed to any *Delia*, nor even to Jupiter. Thus, Plutarch observes, that it was a day consecrated to Jupiter, when *Delia* was made to take the poison to which he was condemned; whereas they waited thirty days to give it to Socrates, by reason of the *Delia*.

According to Theophrastus, the *Delia* were first instituted in the sixth year of the Peloponnesian war, after the

Antemur

Athenians had extirpated the life of Delos, removed all the tombs out of it, and ordained, that nobody should either be born or die in it; but that all the sick people should be removed into a little island, called Rhenea; though the Ionians, and the neighbouring islands of Ionia, had long before that time held a fort of *Delos*; that is, feasts and games, like those which the Athenians celebrated afterwards.

DELIAC, DELIACUS, among the *Ancients*, denoted a poulterer; or a person who sold fowls, fatted capons, &c. The traders in this way, were called *Deliaei*; the people of the life of Delos first practised this occupation. They also sold eggs, as appears from Cicero, in his *Academic*, lib. viii. cap. 8. Pliny, lib. x. cap. 30. and Columella, lib. viii. cap. 8. likewise mention the *Deliaei*.

DELIACAL problem, problema DELIACUM, a famous problem among the ancients, concerning the duplication of the cube. See **DUPLICATION**.

DELIAS, ADELAS, in *Antiquity*, the name of the ship in which the Delian procession was annually made by the Athenians. See **DELIA**.

DELIBAMENTA, in *Antiquity*, a libation offered to the infernal gods, which was always poured downwards; hence that act was expressed by the word *desumere*.

DELIBERATIVE, is applied to that kind, or branch, of rhetoric employed in proving a thing, or convincing an assembly thereof, in order to oblige them to put it in execution.

The *deliberative* kind was much in vogue among the Greeks and Romans, when the orators harangued the people.

To have a *deliberative* voice in the assembly, is when a person has a right to give his advice, and his vote, therein. In councils, the bishops have *deliberative* voices; those beneath them have only consultative voices.

DELICT, in the *Law of Scotland*, is used to express an offence of an inferior degree to a crime, to be punished only by the effect of a civil action, for reparation of private damage.

DELIGATION, Deligatio, that part of surgery which relates to the binding up of wounds, ulcers, broken bones, &c.

That bandages are very useful, and even necessary, for curing the disorders of the human body, is evident not only from the testimony of Hippocrates, Galen, and other eminent physicians; but also from this, that there can scarcely be any operation in surgery performed successfully without their assistance. For should a surgeon perform an operation with the greatest judgment and care, but miscarry in the application of the bandage, all his endeavours would be to no purpose; and more especially in the treatment of wounds, fractures, luxations, and amputations. And we often find that in fractures and luxations, after a proper reduction of the parts, the cure depends more on a skilful application of the bandage, to the part affected, than on the medicines. In the case of violent hemorrhages, a proper application of the bandage and compresses proves the most effectual and speedy remedy, as must be acknowledged by every one who has any skill in surgery: not to mention, that the making and applying a bandage after a gentle and ready manner, is justly reckoned among the good qualifications of a surgeon; as it gains him the esteem of the spectators, and the confidence of the patient, which is of great influence in forwarding the cure: for both the one and the other judge of a surgeon's abilities by his performance on such occasions. See **BANDAGE**.

DELLERS, a kind of Turkish hussars, collected from Servia, Bulgaria, and Croatia. They are violent and furious, whence their name, and disorderly in their attack, which some have ascribed to their belief of predestination. *Encyc.*

DELIMA, in *Botany*, a genus of the *polyandria monogynia* class. This genus has no corolla, the calyx is five-leaved, and the fruit is a double-seeded berry. There is one species.

DELINEATING. See **DESIGNING**.

DELINQUENT, a person who has committed some fault, or offence.

It is the business of a magistrate to be severe in punishing *delinquents*.

DELIQUESCENCE, in *Chemistry*, denotes the property which certain bodies possess of attracting moisture from the air, and of thereby becoming liquid. It is peculiar to saline substances, or bodies containing them, and results from their affinity with water. See **DELIOQUIM**.

DELIOQUIM, or **DELIQUIM animi**, from *deliquo*, I swoon, a swooning, or fainting away, called also *syncope*, *lipothymia*, *lipopsychia*, *eclypsis*, and *asphyxia*.

DELIOQUIM, from *deliquo*, to be dissolved, in *Chemistry*, is the dissolution, or melting, of a salt, or calx, by suspending it in a moist cellar.

Salt of tartar, or any fixed alkali, set in a cellar, or other

cool moist place, and in an open vessel, resolves, or runs, into a kind of liquor, called by the chemists oil of tartar *per deliquum*.

DELIQUIM, is also used, in some authors, for a distillation by means of fire. See **DISTILLATION**.

DELIRIUM, light-headedness, in *Medicine*, a symptom frequent in fevers, caused by internal inflammations, wounds, &c. whereby the mind is disordered to a degree of folly, or even phreny.

Some derive the word from *de*, and *lira*; which, among the ancients, signified a furrow drawn in a right line; whence *delirare*, a *rebus errare*.

Delirium also frequently arises from immoderate losses of blood, whereby the brain is too much weakened; from the stings of venomous beasts; from the feed, or menses, being retained in the womb; from the rotting of a gangrened member, &c.

A disorder in the diaphragm commonly produces a *delirium*.

There are various species and degrees of *delirium*. In some the patient is fierce and outrageous; in others more mild and easy, offering no violence to any body, but only indulging idle, ridiculous discourses; some laugh and sing; others cry and are sullen, &c.

As it is good for a patient under all disorders of the body, to have his mind untouched, or to have all his actions under the command of the ruling faculty, so at other times; so, on the contrary, to be in any manner delirious, or to be deprived in whole or in part of the use of his reason, is a bad prognosis; and in acute diseases often portends death. *James*.

DELIVERY, Parturition, or *child-birth*, the bringing forth of a perfect fetus, or child, out of its mother's womb; whether it be living or dead. See **FOETUS**, **BIATRI**, &c.

To a natural delivery, according to the physicians, are required three conditions: first, that both the mother and the child strive alike, the one to deliver, and the other to be delivered; the second, that it come into the world head foremost, which is its natural posture; and the third, that it be quick and easy, without ill accidents.

When the child presents its feet foremost, or comes acrosth or double, it is no natural delivery; and the Latin call such children *agrippa*, q. d. *agere parit*.

A legitimate delivery is that which happens at the just term, i. e. in the tenth lunar month; and an illegitimate, that which comes either sooner, or later; as in the eighth, or after the tenth. Hoffman says, that the usual time of gestation is nine solar months. Juner is of opinion, that the natural time of delivery is in the fortieth week, from the first suppression of the menses, or the twenty-sixth, or twenty-seventh, from the time when the motion of the fetus is first perceived; and he adds, that it is a good omen if the time of delivery be at or near that of the usual discharge of the menses in a state of health. Women are indeed delivered at seven, eight, nine, ten, and eleven months, and not later; though there are some physicians who hold, that a delivery may be regular in the fourteenth month.

It has been observed, that *deliveries* are more happy in the seventh month than in the eighth, i. e. that the child is easier saved, and more frequently lives, when it comes in the seventh than when in the eighth month.

Monf. Peyssonnel, a physician of Lyons, has a Latin treatise expressly on the term of delivery; wherein he undertakes to reconcile all the apparent contradictions of Hippocrates with respect to it. He holds, that the shortest term of a legitimate birth, according to Hippocrates, is a hundred and eighty-two days, or six complete months; and the longest two hundred and eighty days, or nine months, and ten days; and that the children who come earlier, or later, than those terms, do not live, or are not legitimate.

DELIVERY, symptoms, causes, and precessi of. Besides the more declive symptoms of approaching delivery, women in these circumstances are subject to pains, which are called false and spurious. They exhaust the strength of the patient without promoting the birth: pains of this kind may be distinguished from true labour pains, by their being of a flatulent kind, and running sometimes transversely across the abdomen, and sometimes upwards from it towards the breast; they are usually owing to colicness, a purging, or a plethora. If the *st. trine* is shut during these pains, it may be concluded that they are false; and if the patient is colicive, a clyster should be administered; if a purging attends them, gentle opiates will relieve; and if a plethora, bleeding will be proper. Some have recommended stimulating cordials; but others have observed, that true labour pains are best promoted by opium. The true symptoms of approaching delivery, and the precessi of it, are as follow. Some days before the labour commences, the contents of the belly sink, and its size is apparently diminished: soon after pains are felt, which are at first slight, and return at

considerable intervals; in consequence of these the uterus begins to contract, and a mucous matter is discharged from the vagina; then the pains return quicker, continue longer, and are more severe; the pulse is affected, the skin becomes hotter, the face reddens, and a general agitation follows; the mucus is tinged with blood; the *os tunc* opens, and its edges grow thin; the membranes protrude with the waters, dilating and widening the orifice. The child, at the instant of pain, is raised by the compressed waters from the *os internum* towards the fundus, whilst the uterus itself descends by degrees into the inferior basin. When the pains cease each time, the womb rises, the tumor formed by the membranes disappears, the *os tunc* is relaxed, and the diameter diminished; the child falls upon the lower part of the womb, and may be easily distinguished, as well as the part that presents itself to the passage, through the relaxed membranes. Towards the end of labour, the pains succeed more rapidly, and with greater violence; at first, they usually begin in the small of the back, and terminate about the pudenda, but now they begin in the *regio umbilicalis*, and die away towards the fundament, where they commonly leave a sensibility of weight. The tumor formed by the waters dilating the membranes below the mouth of the womb, dilates the parts, till at length it bursts, and discharges the waters. If the child's head presents fairly, it stops the discharge of the waters. Sometimes the same effort which bursts the membranes, expels the infant, and terminates labour. At other times, the interval is long before the delivery of the child. The head of the child, having passed the *os internum*, enters the vagina, which widens in proportion as it shortens; the perineum is much stretched, and the frenulum sometimes torn in the pouch; the nymphæ are obliterated, and the labia pudendi turned inward, and confounded in the general distention. At length the head forces the *os externum*, and the body readily follows, with the rest of the waters mixed with blood. In this last period the woman trembles, and is convulsed, but is soon relieved by the expulsion of the child; some time after which, returning efforts are exerted for the exclusion of the PLACENTA.

The proximate cause of delivery is the contraction and compression of the womb, which is muscular and reticulated, formed of fibres running parallel on its inner surface from the fundus to the neck, of others crossing these diagonally, and of others again horizontally interlaced, and closely wove towards the fundus; and the irritation which the womb suffers at the end of pregnancy from the increased bulk of the fetus, and the consequent distention of the uterine fibres beyond their limited dimensions, is the remote cause of delivery. For a recital of the principal circumstances attending delivery in cases of difficult and preternatural labour, see LABOUR.

In order to delivery in a natural labour, the most convenient posture both for the woman and her assistant, is that of lying on her left side upon a bed, with the knees drawn up towards the belly. The person who assists on this occasion should be attentive and patient, and watch every opportunity of siding the efforts of nature, without forcing them. Whenever he examines the patient by touch, in order to know the state of the uterus, he should convey a small portion of some oily matter, as soft pomatum, &c. into the vagina, to anoint the mouth of the uterus, that it may dilate itself with greater ease and expedition. When the infant presents itself for birth, he may gently draw it forward, observing that it is not in any part entangled by the navel-string. When it is brought alive into the world, it should be laid on its side, that it may breathe more freely, and have its face kept out of the waters, &c. discharged, during the delivery. If after the delivery of one child, the uterus is much distended, and the operator upon touch finds another set of membranes, he may conclude that another child remains in the uterus; he should therefore tie the navel-string of the first in two places, and wait for pains coming on to deliver the next, unless it presents itself in a bad position, in which case it should be brought away by the feet. But if after the delivery of one child, the uterus is contracted into a firm hard ball above the *os pubis*, he may infer that there is not another, and proceed to bring away the secundines. When the infant is disengaged from the navel-string, which now hangs out of the vagina, the operator should twist it about two or three fingers of his left-hand, then passing his right-hand up the vagina, he must, with his thumb and fore-finger, hold the navel-string as near the secundines as he possibly can; and if on drawing the navel-string gently, he perceives the after-birth advancing gradually, there is hope that he may soon bring it away. If, on the contrary, he perceives, that it does not in the least yield to his attempts, it adheres too strongly to the uterus; in this case he must draw the navel-string sometimes to the

right, and sometimes to the left, in order gradually to disengage the secundines. But this must be done gently, and without the least violence. If, through inadvertence and precipitation, the navel-string should be pulled with violence, it might be broke, which would render the extraction of the after-birth very difficult, or the secundines being forcibly separated from the uterus might occasion an hemorrhage, in consequence of a rupture of the vessels of the womb, or it might bring along with it the bottom of the womb; a falling down of which often occasions the death of the mother. See SECUNDINÆ.

As soon as the woman is delivered, the parts of generation should be covered with a moderately warm cloth, consisting of several folds. She is to be kept warm in bed, and left for some time in a state of repose. James and Motherby's Med. Dict. See LABOUR, LIVING IN, PREGNANCY, &c. &c.

Bartholine has composed a book, *De Infinitis Partus Vis*, on the extraordinary passage of the fetus; where he gives divers instances of very extraordinary deliveries. Some have been delivered by the navel, and others by the anus. See Salmuth, Obs. 94. Cent. 3. Phil. Trans. N° 416. p. 435.

In the year 1686, at Leckerherck, eight or ten leagues from the Hague, the wife of one Christian Claes was delivered of five children: the first was a boy, who lived two months; seventeen hours afterwards came a second son, who was dead; twenty-four hours afterwards a third son was born, who lived about two hours; in twenty-four hours more she had a fourth, dead; lastly, she died in bringing forth the fifth, who died also in the birth.

DELIVERY, in Law, is an essential requisite of a valid DEED, which is done by the party himself, or his attorney, lawfully authorized, and expressed in the attestation. This delivery is either absolute, i. e. to the party or grantor himself; or conditional, to a third person to hold, till some conditions be performed on the part of the grantor.

DELPHIN, in Literary History. See DAUPHINS.

DELPHINIA, in Antiquity, feasts which the inhabitants of Egina celebrated in honour of Apollo, furnished Delphinus, so called, as it is pretended, because he assumed the form of a dolphin to conduct Castalus and his colony from the isle of Crete to the *Sinas Crissani* Delphinium, one of the courts of judicature of the Athenians; so called from the proximity of the place, where they held their assemblies, to the temple of Apollo Delphinus.

DELPHINIUM, in History. See LARACUR.

DELPHINUS, the *Delphin*, in Astronomy, a constellation of the northern hemisphere; whose stars, according to Ptolemy, are 10; according to Tycho, as many; according to Hevelius 244, and according to Mr. Flamsteed, 28. The longitude, latitudes, magnitudes, &c. whereof, are as follow:

Names and situations of the stars.	Right Ascension.	Longitude.	Latitude.	Magnitude.
	Sign.		N.	
First of three in the tail	♐	49 30 40	54 30	6
Between the tail and the preceding rhombus	♐	50 44 27 50	0 21	3
That immediately precedes the tail	♐	50 30 40	48 0	6
North of the following in the tail	♐	51 12 43 10	57 3	3
Preced. South in the rhombus	♐	51 14 31 55 73	3	
South of the following, in the tail	♐	50 56 54 31 40	1	
Between the tail and the hind rhombus	♐	51 54 33 38 14	0

DELPHINI, in Ichthyology. See DOLPHIN.

DELPHOS, in Antiquity, now called CALISI, the capital of Phocis in Achaia; anciently much celebrated for its temple, and oracle of Apollo. This temple was a magnificent structure, enriched with innumerable gifts; in it was the dark cave Pythium, where the priestess, named PYTHIA, sitting on a tripod, or three-legged stool,

flood, pretended to receive the inspiration of the god, swelling, foaming, and raving, like one distracted. The answers were always ambiguous, and so mysterious, that it was difficult to understand them; yet were they plainer than others; for Hermes the philosopher says, that those who did not understand the answers given at Dodona, came thither for an explanation. *Delphi* stands in the middle of Greece, and was by the ancients called the navel of the earth; the poets saying, that Jupiter let fly two eagles, the one from the east, and the other from the west, that he might discover the middle; and that those eagles met at this place. At present the town of Calistri does not consist of above two hundred houses, and those very ill built. It stands between Salena and Liviada, about ten miles distant from the latter, on the south side of mount Parnassus, so famous in antiquity, and sacred to the Muses and Apollo.

DELTOIDES, in *Anatomy*, a triangular muscle of the shoulder, thus called from the Greek *deltos*, Δ , and *idos*, form. See *Tal. Anat. (Myol.) fig. 1. n. 21. fig. 6. n. 10.* It arises exactly opposite to the trapezius, from one third part of the clavicle, from the acromion, and spine of the scapula, and is inserted tendinous into the middle of the os humeri, which bone it lifts up directly; and it assists, with the supra spinatus, and coracobrachialis, in all the actions of the humerus, except the depression; it being convenient, that the arm should be raised and sustained, in order to its moving on any side.

DELTOIDEUS, among *Botanists*. See *LSAR*.

DELTOION, a constellation, the same as the Northern Triangle, see *Ice*.

DELUBRUM, in *Roman Antiquity*, a temple with a large space of consecrated ground round it. See *TEMPLE*.

DELUGE, **DELUVIUM**, in *Natural History*, a flood, or inundation, of water, covering the earth, either in the whole, or part.

We meet with divers accounts of *deluges* in ancient history, both sacred and profane: that which happened in Greece, in the time of Deucalion, called *deluvium Deucalionem*, is famous: this *deluge* only overflowed Thesaly. Its date is fixed to the year before Christ 1579, being the third year before the Israelites coming out of Egypt, according to the computation of Petavius, Rat. Temp. par. i. lib. i. cap. 7.

The *deluge* of Ogyges happened near three hundred years before that of Deucalion, 1020 years before the first Olympiad, and 1795 before Jesus Christ, according to the same author, Rat. Temp. par. i. lib. i. cap. 4. par. ii. lib. ii. cap. 5. This only ravaged Attica.

These two *deluges* are frequently mentioned, in ancient Greek authors, under the denomination of *cataclysmus prius*, and *posterior*.

Of the like kind were those inundations in the Netherlands, which, in 1727, overwhelmed and covered with sea all that part now called the Gulf Dollart in the United Netherlands; and in 1421, all that part between Brabant and Holland.

But the most memorable *deluge* is that which we particularly, by way of eminence, call the *deluge*, or the *universal deluge*, or *Noah's flood*; recorded in Scripture as a general inundation sent by God to punish the corruption of the world, at that time, by destroying every thing (Noah and his family, and what was shut up with him in the ark, only excepted) from the face of the earth.

This flood makes one of the most considerable epochs in chronology. Its history is given by Moses, Gen. ch. vi. and vii. Its time is fixed, by the best chronologists, to the year from the creation 1656, answering to the year before Christ 2293. From this flood, the state of the world is divided into *deluvian*, and *antediluvian*.

The *deluge* has been, and remains, a subject of much inquiry and dispute among naturalists, critics, &c. The points chiefly controverted may be reduced to three: first, its extent; viz. whether it were general, or partial; secondly, its natural cause; and, thirdly, its effects.

1. The immense quantity of water, requisite to furnish an universal *deluge*, has occasioned several authors to suspect it only partial. An universal *deluge*, they think, had been unnecessary, considering the end for which it was brought; viz. to extirpate the wicked inhabitants. The world was then but new, and the people not very many; the holy Scriptures making only eight generations from Adam to Noah. It was but a small part of the earth that could be yet inhabited: the country about the Euphrates, which is supposed to have been the scene of the first antediluvian inhabitants, was sufficient to bear them all. Now Providence, say they, which ever acts wisely, and frugally, would never have disproportioned the means to the end, so far as to overflow the whole globe, only to drown a little corner of it. They add, that, in the Scripture-language, the whole earth expresses no more than all the inhabitants; and on this principle advance,

that an overflowing of the Euphrates and Tigris, with a vehement rain, &c. might answer all the phenomena of the *deluge*.

But the *deluge* was universal. God declared to Noah, Gen. vi. 17. that he was resolved to destroy every thing that had breath under heaven, or had life on the earth, by a flood of waters: such was the menace; such the execution. The waters, Moses assures us, covered the whole earth, buried all the mountains, and were no less than fifteen cubits above the highest of them: every thing perished therein; birds, beasts, men, and all that had life, excepting Noah, and those with him in the ark, Gen. vii. 19, &c. Can an universal *deluge* be more clearly expressed? If the *deluge* had only been partial, there had been no necessity to spend an hundred years in the building of an ark, and shutting up all the sorts of animals therein, in order to re-stock the world: they had been easily and readily brought from those parts of the world not overflowed, into those that were; at least, all the birds would never have been destroyed, as Moses says they were, so long as they had wings to bear them to those parts where the flood did not reach. If the waters had only overflowed the neighbourhood of the Euphrates and Tigris, they could not be fifteen cubits above the highest mountains; they could not have risen to that height, but they must spread themselves, by the laws of gravity, over the rest of the earth: unless, perhaps, they had been retained there by a miracle; and, in that case, Moses, no doubt, would have related the miracle, as he did that of the waters of the Red sea, and the river Jordan, which were sustained in a heap, to give passage to the Israelites, Exod. xiv. 22. and Josh. iii. 16. Add, that, in regions far remote from the Euphrates and Tigris, viz. in Italy, France, Switzerland, Germany, England, &c. there are frequently found, in places many fathoms of leagues from any sea, and even in the tops of high mountains, whole trees sunk deep under-ground; as also teeth and bones of animals, fishes entire, sea shells, ears of corn, &c. petrified; which the best naturalists are agreed could never have come there but by the *deluge*; to which may be added the almost universal traditions of this great event in all countries of the globe.

2. The *deluge* allowed universal, the philosophers are solicitous to find water to effect it.

Moses brings it from two sources: the fountains of the great deep were broken up; and the windows of heaven were opened. Dr. Burnet, in his Telluris Theoria sacra, shews, that all the waters of the ocean were not near enough to cover the earth fifteen cubits above the tops of the highest mountains. According to his computation, no less than eight oceans were required. Supposing the sea, therefore, drained quite dry, and all the clouds of the atmosphere dissolved into rain, we should still want much the greatest part of the water of a *deluge*.

To get clear of this embarrassment, many of our best naturalists, as Steno, Burnet, Woodward, Scheuchzer, &c. adopt Des Cartes's system of the formation of the earth. That philosopher will have the primitive world to have been perfectly round and equal, without mountains, or valleys; and accounts for its formation on mechanical principles, by supposing it at first in the condition of a thick turbid fluid, replete with diverse heterogeneous matters, which, subsiding by slow degrees, formed themselves into different concentric strata, or beds, by the laws of gravity; and thus, at length, left a dry, solid earth. Dr. Burnet improves on this theory: he supposes the primitive earth to have been no more than an orbicular crust, investing the face of the abyss, or deep, which grew chinky, clavy, burly, and fell down into the water, and to be drowned its inhabitants.

The same theorist adds, that by this catastrophe, the globe of the earth was not only shaken, and broken in a thousand places, but the violence of the shock it then underwent shifted its situation; so that the earth, which before was placed directly under the zodiac, became thenceforth oblique to the same. Whence arose the difference of seasons, which the antediluvian earth was not exposed to.

Dr. Burnet's hypothesis is very elegantly recited; but it not only contradicts the physical principles of nature, but is also utterly inconsistent with the sacred text above cited, which expressly mentions mountains as the standard of the height of the water; or with that other passage, Gen. viii. 22. where God, promising not to bring any more *deluges*, but that every thing should be restored to its ancient state, says, that seed-time and harvest, and cold and heat, and summer and winter, and day and night, shall cease no more. See Keil's Exam. of the Theory of the Earth.

Other authors, supposing a sufficient fund of water in the abyss, or sea, are only concerned for an expedient to bring it forth: accordingly, some, as Mr. Ray, &c. have recourse

recourse to a shifting of the earth's centre, which, drawing after it the water out of its channel, overwhelmed the several parts of the earth successively. But this could only occasion a partial deluge in that part of the globe towards which the centre of gravity was translated: nor can the possibility of such a translation be allowed, since the centre of gravity is the necessary result of the materials composing our globe, and not alterable whilst the parts remained in the same position.

Dr. Hook's opinion of the compression of a shell of earth into a protuberant spheroid, thereby pressing out the water of an abyss under the earth, may very well account for the waters overflowing two opposite zones of the globe; but the middle zone being by much the greater part of the earth's surface, must by this means be raised higher from the centre, and consequently arise more out of the water than before.

Dr. Halley ascribes the deluge to the shock of a comet, or some other such transient body, whereby the polar and diurnal rotation of the globe would be instantly changed. The great agitation that must have been occasioned by it in the sea, he observes, would be sufficient to account for all those strange appearances of heaping vast quantities of earth and high cliffs upon beds of shells, which were once the bottom of the sea; and raising up mountains where none were before. Such a shock as this impelling the solid parts, would occasion the waters, and all fluid substances that were unconfin'd, as the sea is, to run violently with an impetus towards that part of the globe where the blow was received, and that with force sufficient to take with it the very bottom of the ocean, and remove it to the land. In this case, it is much more difficult to say, how Noah and his family could be preserved, than how all other creatures were destroyed: such a shock would change the length of the day and year, by altering the axis of the globe, according to the obliquity of the incidence of the stroke. It is objected to this system, that such a shock must have brought on the deluge instantaneously, and not gradually, as it is said to have happened. Phil. Trans. N° 383. p. 120, or Abr. vol. vii. p. 3. &c.

The ingenious Mr. Whiston, in his New Theory of the Earth, has a very ingenious hypothesis, similar to that suggested by Dr. Halley, with respect to the primary cause of the deluge, but much more largely applied and explained. He shews, from several remarkable coincidences, that a comet, descending in the plane of the ecliptic towards its perihelion, passed just before the earth on the first day of the deluge; the consequences whereof would be, first, that this comet, when it came below the moon, would raise a prodigious, vast, and strong tide, both in the small seas, which, according to his hypothesis, were in the antediluvian earth, for he allows no great ocean there, as in ours; and also in the abyss, which was under the upper crust of the earth; and that this tide would rise, and increase all the time of the approach of the comet towards the earth; and would be at its greatest height when the comet was at its least distance from it. By the force of which tide, as also by the attraction of the comet, he judges, that the abyss must put on an elliptic figure, whose surface being considerably larger than the former spherical one, the outward crust of the earth, incumbent on the abyss, must accommodate itself to that figure, which it could not do while it remained solid, and conjoined together. He concludes, therefore, that it must of necessity be extended, and at last broke, by the violence of the fluid tides, and attraction; out of which, the inclosed water issuing, was a great means of the deluge; this answering to what Moses speaks of the *fountains of the great deep being broken open*. Again, the same comet, he shews, in its descent towards the sun, must have passed so close by the body of the earth as to involve it in its atmosphere, and tail, for a considerable time; and of consequence, it must have left a vast quantity of its vapours, both expanded and condensed, on its surface; a great part of which, being afterwards rarified by the solar heat, would be drawn up again into the atmosphere, and afterwards return again in violent rains; and this he takes to be what Moses intimates by the *window of heaven being opened*; and particularly by the *fiery days rain*. For as to the following rain, which, with this, made the whole time of raining a hundred and fifty days, Mr. Whiston attributes it to the earth coming a second time within the atmosphere of the comet, as the comet was on its return from the sun. Lastly, to remove this vast orb of waters again, he supposes a mighty wind to have arisen, which dried up fountains, and forced the rest into the abyss again through the clefts by which it came up; only a good quantity remained in the abyss of the great oceans, now first made, and in lesser seas, lakes, &c.

To the credit of this theory, it must be observed, that it

was at first only proposed hypothetically: that is, the author only supposed (such a comet, merely as it would account with, and philosophically, for the phenomena of the deluge), without any assurance, that there really was any comet so near the earth at that time; and the hypothesis pleased even under such circumstances; but, upon further considerations, he has since, he thinks, proved, that there actually was a comet near the earth at that time, or 28th November, in the 2355th year of the Julian period, or the 2349th year before Christ, to which time he assigns the beginning of the deluge, viz. the same great comet which appeared again in 1680. The author no longer, therefore, looks upon it as an hypothesis, but has republished it in a particular tract, intitled, *The Cause of the Deluge demonstrated*.

3. But the great difficulty still remains. The orderly strata, or layers of the earth, with the ruivins, or remains of fishes, as their teeth, bones, shells, &c. both marine, and fluviatile, found in the bodies even of the most solid strata, and in flints, marbles, &c. are not yet accounted for. Those who adhere to Des Cartes's system, as Steno, &c. take the finding of the part of terrestrial, and aquatic animals, branches of trees, leaves, &c. in the beds, or strata of stone, to be a direct proof of the primitive fluidity of the earth. But then they are obliged to have recourse to a second formation of strata, much later than the first; because at the time of the first there was neither plant nor animal, in being. Strata, therefore, maintains second formations, occasioned at different times by extraordinary foundations, earthquakes, volcanos, &c. But Burnet, Woodward, Scheuchzer, &c. choose rather to attribute a second general formation to the deluge; without excluding, however, the particular ones of Steno. But the great objection against this system of fluidity, is mountains; for the whole globe being liquid, whence should such inequalities arise? Mr. Scheuchzer, rather than part with a system which seems so promising, gives into the opinion of those who hold, that, after the deluge, God, to remit the waters into their subterranean reservoirs, broke, and displaced, with his own slightly hand, a great number of strata, that were before horizontal, and raised them above the surface of the earth; whence it is, that the strata in mountains, though unconformable, are never horizontal. Hist. de l'Acad. 1708. p. 32.

Dr. Woodward, taking the several strata for the sediments of a deluge, and considering the circumstances of those fishes, shells, and other extrins, found in them, draws several inferences, which very much illustrate the effects of the deluge. As, first, that these marine bodies, and other spoils of salt-water fishes, were borne forth out of the sea, by the universal deluge; and, on the return of the water back again, were left behind upon the land. Secondly, that while the flood covered the globe, all the solid matters, as stones, metals, minerals, and fossils, were totally dissolved, and the cohesion of their corpories destroyed; and that their corpories, with those of the less solid bodies, as earth, flesh of animals, and vegetables, were sustained promiscuously in the water, and made one common mass. Thirdly, that all the mass, thus sustained, was at length precipitated to the bottom; and that according to the laws of gravity, the heaviest settled first, and the rest in order. And that the matters, thus subsiding, constituted the several strata of stone, earth, coal, &c. Fourthly, that these strata were originally all parallel, even, and regular, and rendered the surface of the earth perfectly spherical; and that the whole mass of water lay upon them, and constituted a fluid sphere encompassing the globe. Fifthly, that after some time, by the force of an agent seated within the earth, these strata were broken on all sides of the globe, and their situation varied; being elevated in some places, and depressed in others; whence mountains, valleys, gorges, &c. with the channel of the sea, islands, &c. In one word, the whole terraqueous globe was put, by this disruption, and dislocation of the strata, into the condition we now behold it in. Sixthly, that upon the disruption of the strata, and the depression of some, and elevation of other parts, which happened towards the end of the deluge, the mass of water fell back again into the depressed, and lowest parts of the earth, into lakes, and other cavities, and the channel of the ocean, and through the fissures, whereby this communicates with the abyss, which it filled till it came to an equilibrium with the ocean. Nat. Hist. of Earth, p. 1. and 2.

But of all the systems yet advanced, there seems none better calculated to solve the phenomena of these petrified exuvies, than that of M. de la Pyrene. The antediluvian world, according to this author, had an external sea, as well as land, with mountains, rivers, &c. and the deluge was effected by breaking the subterraneous caverns, and pillars thereof, with dreadful earthquakes.

and causing the same to be for the most part, if not wholly absorbed, and swallowed up, and covered by the seas that we now have. Lastly, this earth of ours arose out of the bottom of the antediluvian sea, and in its room; just as many islands are swallowed down, and others thrust up in their stead.

From this system, which is very agreeable to Scripture, the great difficulties that clog all the other systems, seem easily solved. It is no longer a wonder, that shells, and shell-fish, and the bones of fishes, and four-footed creatures, with fruits, &c. should be found in beds and quarries, in mountains and valleys, and the very bowels of the earth; for here they bred in the antediluvian sea; thither they were elevated with the hills and mountains, in the time of the *deluge*; and there they fell into, were absorbed, and buried in chasms, and holes, and clefts, that would necessarily happen in the extrusion of the earth. Phil. Trans. N^o. 306.

Mr. King has more lately adopted an hypothesis resembling this last. He observes the *deluge* to have been a fire from within the bowels of the earth, which, at the appointed time, burst forth with great violence under the sea, and raised up the bottom of the ocean, so as to pour out the waters over the face of what was before dry land, which by that means became the sea, and has since continued, and that which was before the bottom of the sea became dry land. An earthquake thus occasioned will account, he supposes, for the access of the *deluge*, and the confused disposition of marine productions in the post-diluvian earth. Phil. Trans. vol. viii. p. 44, &c. Mr. Buffon recites the principal hypotheses relating to the universal *deluge*, in his Hist. Nat. tom. i.

DELUGE of Demerion. See DEUCALION.

DELVIN, in Natural History, a name sometimes given by the miners in Cornwall to that sort of talsey stone or flint, which they more generally call *killar*; but in some places, as at Lowanowen, they use it as the name of a coarse, but very hard stone, in which the ore lies. The ore is tin, and is considerably rich there, but the hardness of this stone makes it difficult to be got out.

DEMAIN, or **DEMERNE**, in its popular sense, denotes the lord's manor-land, with the lands thereto belonging; which he and his ancestors have from time to time kept in their own manual occupation. See MANOR.

DEMAIN, or **DEMERNE**, in a law-fence, signifies, according to Hutton, *patrimonium domini*, the lord's patrimony; called also *domain*, and by the civilians, *dominium*.

The same author proves, that lands to be *domain*, which a man holdeth originally of himself; and those to be *freedom*, which he holdeth of a superior lord.

In England, no common person has any *domain*, simply understood; for all depends either mediately, or immediately on the crown. When a man, therefore, in pleading, would signify his land to be his own, he saith, that he is or was seised thereof in his *domain*, as of fee; whereby he means, that although his land be to him and his heirs for ever, yet it is no true *domain*, but depends upon a superior lord, and he holdeth by service, or rent in lieu of service, or by both service and rent.

DEMAIN is sometimes also taken, more largely, for lands and tenements held for life, &c. and sometimes more strictly for such only as are generally held in fee.

DEMAIN is sometimes again used for a distinction between those lands that the lord of a manor has in his own hands, or in the hands of his lessee, demised upon a rent, for a term of years, or life; and such other lands, pertaining to the said manor, which belong to the free, or copyholders.

The reason why the copy-hold is accounted *domain*, is because they, who are tenants to it, are judged in law to have no other right but at the will of the lord; so that it is reputed still, after a sort, to be in the lord's hands; and yet in common speech that is ordinarily called *domain*, which is, neither free, nor copy-free.

DEMAIN, again, is used in a more special signification, in opposition to *frank-fee*.

Thus, those lands which were in the possession of Edward the Confessor, are called *ancient domain*; and all others are called *frank-fee*, and the tenants who hold any of those former lands, are called *tenants in ancient domain*; and the others, tenants in *frank-fee*, and also, tenants at *common law*. The reason is, because tenants in *ancient domain* cannot be sued out of the lord's court.

DEMAND, in its proper sense, denotes a calling for, or requiring one's due.

DEMAND, in Law, has a more special signification, as contradicting the word *plaint*: for all civil actions are pursued, either by *demands* or *plaints*; according to which the pursuer is called either *demandant*, or *plaintiff*: viz. in real actions, *demandant*; and in personal actions, *plaintiff*.

Where the party pursuing is called *demandant*, the party

pursued is called *tenant*; and where the former is called *plaintiff*, the latter is termed *defendant*.

There are two kinds of *demands*: the one in *deed*, *de facto*, as in every precept; the other in *law*, *de jure*; such is entry in land, distress for rent, &c.

If a man release another from a *demand*, it is the best release the releasee can have, and shall redound most to his advantage. A release of facts is more large than of quarrels or actions; and a release of *demands* more large and beneficial than either: by a release of all *demands* to the defendant, the right of entry into the land, and all contained therein, is released; and he that releaseeth all *demands*, excludes himself from all actions, entries, and seizures. But it is no bar to a writ of error to release an outlawry.

DEMANDANT, *Petitor*, he who is actor, or plaintiff, in a real action; thus called, because he *demand*s lands, &c.

DEMARCHUS, in Geography, the chief of a region, or district, in the country of Aulica.

The Athenians divided their country into certain regions, or districts, which they called *hoai*, i. e. *people*; and established a magistrate at the head of each, under the denomination of *demarches*, *demarches* of *hoai*, and *agorae*, *viz. governments*.

It was also an appellation given to the chief magistrate of the city of Memphis.

DEMEMBRE, in Heraldry, is when an animal is *dismembered*, i. e. the limbs cut off its body.

DEMESNE. See **DEMAIN**.

DEMETRIA, *Demetria*, in Antiquity, a festival in honour of Ceres, called by the Greeks *demetria*, *demetria*, of *de*, i. e. *year*, *carib*, and *metria*, *metria*. It was usual on this occasion for the worshippers to lath themselves with whips made of the bark of trees, and called *pagurae*. Pott. Archæol. Græc. tom. I. lib. II. cap. 20. p. 379.

DEMETRIA was likewise the name of another festival celebrated by the Athenians in honour of Demetrius Poliorcetes, and was the same with that afterwards called *Demetria*. Pott. loc. cit.

DEMI, a word of the same use and effect in the French language with *semi*, in the Latin and English; being formed from *dimidium*; and used, in composition with other words, to signify half.

In words borrowed from the Latins, we use *semi*; and in those from the French, we retain their *de*. See **SEMI**.

DEMI, or **DEMY**, in Heraldry, signifies the half of a thing; as, a *demmy lion*, &c.

Colombiere has what he calls *croix & demy*, a cross and a half; being a staff crossed in the upper-part like the Cavalry cross; and having but one arm at the lower-part.

DEMI-AIR, or **DEMI-VOLT**, in Hersemanship, is one of the seven artificial motions of a horse; being an air, in which his fore-parts are more raised than in terra a terra; but the motion of the horse's legs is more quick in the latter than in the *dress-halt*.

DEMI-BASTION, is a kind of fortification, that has only one face, and one flank. See **BASTION**.

DEMI-CANNON, a piece of ordnance, usually about six inches bore, 5600 pounds weight, ten or eleven feet long, and carrying a shot of 30 or 32 pound weight.

It carries point-blank 150 paces; its charge of powder is 14 pound weight.

There are also two sizes of *demmy-cannon* above this, which are something larger; as, the ordinary *demmy-cannon*, which is six inches bore twelve feet long, weighs 5600 pounds; its charge of powder 17 pounds 2 ounces, carries a shot six inches and a half diameter, and whose weight is 32 pounds; this piece throws point-blank 162 paces.

Demmy-cannon of the largest size, is six inches bore, twelve feet long, 6000 pounds weight; its charge is 18 pounds of powder, and it carries 180 paces. See **CANNON**, and **ORDNANCE**.

DEMI-CROSS, an instrument used by the Dutch to take the sun's altitude, or that of a star at sea; but instead of which we use the cross-staff or fore-staff. See **Tab. II. Astronomy**, fig. 67.

The staff A G is graduated easily, being only a line of whole tangents, whose radius is E B, the length of the cross-piece, or transom. It hath three vane; a horizontal vane, as A f a right vane, as H; and the shade vane, as E.

When the vane are on the staff and cross-piece, to take the sun's altitude, hold the instrument with the transom as upright as you can, and looking through the right vane, as H, look for the horizon through the slit in the horizon vane, and then slide the cross-piece or transom to and fro, till you make the shade of the vane at E to fall at the same time upon the slit of the horizon vane, and also at A; then are the degrees cut on the staff, by the edge of the cross-piece, the sun's altitude required. But to take the height of a star, you must remove the horizon vane A, and put it on the end G, and transfer

the light vane H to A; then holding up the instrument as before, looking through the light vane, see for the horizon through the horizon vane, and for the star by the shade vane, sliding the tranfom to and fro, till the horizon and star are both seen by their respective vanes, and then the tranfom will cut the degrees of the star's altitude on the staff, allowing about eight or ten minutes for your height above the level of the water, as mult be done in all fuch cafes.

DEMI-CULVERIN, is a piece of ordnance commonly 4 $\frac{1}{2}$ inches bore, ten feet long, 2700 pounds weight; its charge is 7 pounds 4 ounces of powder; and it carries a shot of 10 pounds, 11 ounces, and fhoos point-blank 175 paces.

Demi-culverin of the laft fize, is 4 $\frac{1}{2}$ inches bore, ten feet long, 2000 pounds weight; it carries a ball of 4 inches diameter, its charge is 6 pounds 4 ounces of powder, and its level range is 174 paces.

Demi-culverin of the largft fort, is 4 inches $\frac{3}{4}$ bore, ten feet long; its charge of powder is 8 pounds and 8 ounces; the ball is 4 $\frac{1}{2}$ inches diameter, weighs 12 pounds 11 ounces; and the point-blank fhoos 178 paces. See **CANNON**, and **ORDNANCE**.

DEMI-DITONE, in *Mufic*, is ufed by fome for a third minor.

DEMI-GOD, &c. See **GOD**, **HEAD**, &c.

DEMI-GORGE, in *Furftation*, is half the gorge, or entrance, into the ballion; not taken directly from angle to angle, where the ballion joins to the curtain, but from the angle of the flank to the centre of the ballion; or the angle the two curtains would make, were they thus produced to meet in the ballion.

DEMI-HAQUE. See **HAQUEBUL**.

DEMI-LUNE, *Half-Moon*, in *Furftation*, an outwork, as EFGHK (Tab. Fort. fig. 3.) confifting of two faces, and two hule flanks; frequently built before the angle of a ballion, and fometimes alfo before the curtain, though now much difufed. The gorge terminates in a crefcent or half-moon, whence the denomination *semi-lune*. See **RAVELIN**.

DEMI-QUAVER, is a note in mufic, two of which are equal to the quaver.

DEMI-SEMI-QUAVER. See **QUAVER**.

DEMI-SEXTILE. See **SEMI-SEXTILE**.

DEMISE, in *Law*, is applied to an eftate either in fee; fimple, fee-tail, or for term of life, or years; and fo it is commonly taken in many writs.

The king's death is, in law, termed, the *demise* of the king.

DEMISE of the King does not difcontinue any writ or process. Vide *St. 1 Ed. VI. cap. 7. fect. 1, 2, 3.*

Nor does it determine any commiffion civil or military, or great office of ftate, but they fhall continue in force for fix months after the fovereign's *demise*, unlefs made void by the next fucceffor. Stat. 7 & 8 Will. III. cap. 27. fect. 21. 1 Ann. ftat. 1. cap. 8. 6 Ann. cap. 7. fect. 8.

Neither is a parliament thereby determined till after fix months. 7 & 8 Will. III. cap. 15.

Nor is a defendant, who hath pleaded to an information, obliged to plead to it again. But he may plead again upon requit made to the court, within five months after the *demise*. 4 & 5 Will. & Mar. cap. 18. fect. 7.

DEMITA, and **REDEMPTA**, denote a conveyance where there are mutual leffes made from one to another of the fame land, or fomething out of it.

DEMI-VILLS. See **VILL**.

DEMIURGE, *Demourge*, from *deus*, which denotes a public fervant and *tyran*, work, in the *Mythology* of the *Eastern Philofophers*, was one of the *gods*, employed by the fupreme Deity in the creation of the world. The character they give him is a compound of fhining qualities, and inftoppable arrogance; and his excefive luft of empire effaces his talents and virtues. He is reprefented as claiming dominion over the new world he has formed as his 'foreign right; and, excluding totally the fupreme Deity from all concernment in it, he demands from mankind, for himfelf and his affociates, divine honours.

DEMOCRACY, a form of government, wherein the fovereignty, or fupreme authority, is lodged in the people, who exercise the fame by perfons of their own order, deputes for that purpofe.

The word is formed of the Greek *deus*, people, and *spatras*, to command, govern.

The moft flourishing democracies were thofe of Rome and Athens; the modern republics, as Venice, and the United Provinces, are rather ariftocracies than democracies. The government of Roff, however, is a democracy, and fo are fome of the free cities in Germany.

In a democracy, where the right of making laws refides in the people at large, public virtue, or goodnefs of inten-

tion, is more likely to be found than either of the other qualities of government; and therefore it ufually poffeffes a confiderable degree of patriotifm and public fpirit. Democracies are ufually the belt calculated to direct the end of a law; ARISTOCRACIES to invent the means by which that end fhall be obtained; and MONARCHIES to carry thofe means into execution. See **REPUBLIC**.

DEMOISELLE, the *dancing-bird*, a long-legged and long-necked bird of the crane kind, a native of Numidia. It is remarkable for its jumping or dancing in its walk. It has the fame kind of plication in the wind-pipe with the common CRANE. See *Tab. II. of Birds*, N^o 12. Phil. Trans. vol. IV. p. 211.

DEMON. See **DEMON**.

DEMONIAC. See **DEMONIAC**.

DEMONIACAL poffeffion. See **DEMONIACAL poffeffion**. **DEMONIUS** *lepis*, in *Natural Hiftory*, a name given to a Roome famous among the writers of the middle ages for a number of imaginary virtues, fuch as rendering people victorious over their enemies, and the like. All the description they have left us of it is, that it was variegated with two colours laid in lines fo as to represent a rainbow. It was probably an agate.

DEMONSTRABLE, a term ufed in the fchools, to fignify fomewhat that may be clearly and evidently proved.

It is *demonftrable*, that the fide of a fquare is incommenfurable with the diagonal.

DEMONSTRATION, in *Logic*, a fyllogifm in form, containing a clear and irrefragable proof of the truth of a propofition.

A *demonftration* is a convincing argument, the two *premisses* whereof are certain, clear, and evident; whence of neceffity arifes an infallible conclufion. A *demonftration* ufually confifts of three parts: *explication, preparation, and conclufion*.

The *explication* is the laying down of the things fupposed to be given or granted; from which the *demonftration* is to be made.

The *preparation* is fomewhat to be previously done, according to the nature of the *demonftration* intended.

The *conclufion* is a propofition that concludes the thing to be *demonftrated*, fully perfuading, and convincing the mind.

The method of *demonftrating* things in mathematics is the fame with that of drawing conclufions from principles in logic. In effect, the *demonftrations* of mathematicians are no other than feries of *enthymemes*; every thing is concluded by force of fyllogifm, only omitting the *premisses*, which either occur of their own accord, or are fupplied by means of quotations. To have the *demonftration* perfect, the *premisses* of the fyllogifms fhould be proved by new fyllogifms, till at length you arrive at a fyllogifm, wherein the *premisses* are either definitions, or identic propofitions.

Indeed it might be *demonftrated*, that there cannot be a genuine *demonftration*, i. e. fuch a one as fhall give full conviction, unlefs the thoughts be directed therein according to the rules of fyllogifm. Clavius, it is well known, refoived the *demonftration* of the firft propofition of Euclid into fyllogifm: Heronius, and Dapodius, *demonftrated* the whole fix firft books of Euclid; and Henrichus, all arithmetic, in the fyllogifmic form.

Yet people, and even mathematicians, ufually imagine, that mathematical *demonftrations* are conducted in a manner far remote from the laws of fyllogifm; fo far are they from allowing that thofe derive all their force and conviction from thofe. But we have men of the firft rank on our fide the queftion. M. Leibnitz, for inftance, declares that *demonftration* to be firm and valid, which is in the form prefcribed by logic; and Dr. Wallis confeffes, that what is propofed to be proved in mathematics, is deduced by means of one, or more fyllogifms: the great Huygens, too, obferves, that *paralogifms* frequently happen in mathematics, through want of obferving the fyllogifmic form. See **SYLLOGISM**.

Problems confift of three parts: a *propofition, refolution, and demonftration*.

In the *propofition* is indicated the thing to be done.

In the *refolution*, the feveral fteps are orderly rehearfed, whereby the thing propofed is performed.

Laftly, in the *demonftration* it is fhewed, that the things enjoined by the refolution being done, that which was required in the propofition is effected. As often, therefore, as a problem is to be *demonftrated*, it is converted into a theorem; the refolution being the hypothesis, and the propofition the thesis: for the general tenor of all problems to be *demonftrated* is this; that the thing prefcribed in the refolution being performed, the thing required is done.

The fchoolmen make two kinds of *demonftration*: the one *reftiva*, or *proprie quæftio*, wherein an effect is proved by the next caufe. As when it is proved, that the moon is eclipfed,

eclipsed, because the earth is then between the sun and moon. The second *vs. in, or quia*; wherein the cause is proved from a remote effect: as when it is proved, that fire is hot, because it burns; or that plants do not breathe, because they are not animals; or that there is a God, from the works of creation. The former is called *demonstration a priori*, and the latter *demonstration a posteriori*.

DEMONSTRATION, affirmative, is that which, proceeding by affirmative and evident propositions, dependent on each other, ends in the thing to be demonstrated.

DEMONSTRATION, apagogical. See APAGOGICAL.

DEMONSTRATION, geometrical, is that framed of reasonings drawn from the elements of geometry.

DEMONSTRATION, mechanical, is that, the reasonings whereof are drawn from the rules of mechanics.

DEMONSTRATION a priori, is that whereby an effect is proved from a cause, either a next, or remote one; or a conclusion proved by something previous, whether it be a cause, or only an antecedent.

DEMONSTRATION a posteriori, is that whereby either a cause is removed from an effect, or a conclusion is proved by something posterior; whether it be an effect, or only a consequent.

DEMONSTRATIVE, in Rhetoric, one of the genera, or kinds of eloquence; being that which obtains in the composing of panegyrics, eulogies, &c.

Rhetoric is divided into three kinds; *deliberative, demonstrative, and judiciary*. See RHETORIC.

DEMONSTRATIVE, in Grammar, is applied to pronouns which serve to their point out, or indicate a thing; as, *this, that, &c.*

They are also called *definitive*, because they define and limit the extent of the common name, or general term, to which they either refer, or are joined.

DEMONSTRATIVE evidence. See DEDUCTIVE AND EVIDENCE.

DEMULCENTS, Demulcentia, in Pharmacy, are medicines which render the acrimonious humors mild. This they do by obtaining or dissolving their sharp particles.

They are distributed into *general and specific*; the former including those which pertain to all kinds of acrids indifferently; and the latter (such as obtund only a particular kind of serosity). See EMOLLIENTS.

DEMURRAGE, in Traffick, an allowance made to the master of a ship, by the merchants, for staying in a port longer than the time first appointed for his departure.

DEMURRER, in Law, a kind of pause or stop, put to the proceeding of any action, upon some difficult point, which must be determined by the court, before any farther progress can be had in it.

In every action, the controversy is either as to fact, or as to law; the first, decided by the jury; the second, by the judge. Now, if any thing turn up in the cause so rare and difficult, that the judge cannot pronounce upon it, a *demurrer*, or stop, is made, and time taken, either for the court to consider and agree of it among themselves, or otherwise for the judges to meet in the exchequer chamber; there, after hearing counsel on both sides, to determine what is law. For this purpose a *demurrer* book is made up, containing all the proceedings at length, which are afterwards entered on record, and copies thereof, called paper books, are delivered to the judges to peruse.—This *demurrer* is expressed, in our records, by *verba in lege*.

In common law, the defendant sometimes *demurrab* to the plaintiff's count, or declaration; and sometimes the plaintiff *demurrab* to the defendant's plea, by averring, that it is not a sufficient plea in law, &c.

In chancery, the defendant *demurrab* to the plaintiff's bill, averring it to be defective in such and such a point; and demands the judgment of the court thereupon, whether he shall not be compelled to make any farther or other answer thereto.

DEMURRER to evidence takes place, when a record, or other matter, is produced in evidence, concerning the legal consequences, of which there arises a doubt or question in law; in which case the adverse party may, if he pleases, *demur* to the whole evidence. This draws the question of law from the cognizance of the jury, to be decided by the court. But this kind of *demurrer* is now seldom used.

DEMURRER to indictments is incident to criminal cases, as well as civil, when the fact as alleged is allowed to be true, but the prisoner joins issue upon some point of law in the indictment; by which he insists that the fact, as stated, does not amount to the crime charged.

Some have held, that if, on *demurrer*, the point of law be adjudged against the prisoner, he shall have judgment and execution, as if convicted by verdict; but this is denied by others, who maintain, that in such case he shall be directed and received to plead the general issue,

not guilty, after a *demurrer* determined against him. However, upon this doubt, *demurrers* to indictments are seldom used; since the same advantages may be taken upon a plea of not guilty; or, afterwards, in arrest of judgment, when the verdict has established the fact. Blackst. Comm. vol. iv. p. 428.

DEMY Sargus. See HALL BLEED.

DEN, a syllable added to the names of places, and shews their situation to be in a valley, or near woods, as Tenterden, Biddenden, &c.

The word is Saxon *den*, i. e. *vallis*, or *lucus sylvestris*.

DEN and friends, &c. in *Laws*, was a liberty for ships or vessels to run or come ashore. King Edward I. by charter, granted this privilege to the Barons of the cinque ports.

DENARIATUS terra, in *Ancient Law-Books*, as much land as is worth a penny by the year. See FALDING-DEAL. *Sibylla Bartholmæi tract. unum ac. vii. § 5 denariatos terra in radem tenemus*. Dn. Cange.

DENARIUS, in *Antiquity*, the Roman penny; a silver coin equivalent to, from six to eight pence half-penny sterling. See COIN.

The Romans, having for a long time, used brass money, which they call *as*, *quadrans*, &c. of *Ære* and *pænis*, because it was a pound weight, began in the year of Rome 485, to coin silver; and coined first the *denarius*, which was marked with the letter X, because it was worth ten *asses*, and divided into two *quadrants*, marked with V, which were subdivided into two *sestertia*, marked with these three letters, IIS. Afterwards, about the year 537, the silver *denarius* was made to pass for sixteen *asses*, the *quadrans* for eight, and the *sestertius* for four; though in the pay of the army the soldier always received a silver *denarius* for ten *asses*. Pliny, Nat. Hist. lib. xxxiii. cap. 3. Livy, lib. xv.

The most ancient *denarii* have on one side the head of a woman in a helmet, with the inscription ROMA, and the mark of the *denarius* X or X, and some few XVI, and a litta or quadriga on the other; whence they are denominated *bigrati* and *quadrigati*. The next to these in antiquity have the head of Roma, or some other deity, on one side, and on the reverse the image of the mint-master, with historical or emblematical figures. Many of these have the mark X or X, which remained long after the *denarius* passed for sixteen *asses*. A third sort have the head of a consul or general on one side, with an historical or emblematical reverse; few of these have the mark X or X upon them. These three sorts are called *consular denarii*, because they were struck during the republican government by consuls. The imperial *denarii* have commonly the head of the reigning emperor, with his names and titles on one side, and some emblematical figures on the reverse, with suitable inscription. The Romans did not use the *denarius* for a weight, as the Greeks did their drachm, till the Greek physicians coming to Rome, and finding the two coins nearly equal, prescribed by it, as they had been used to do by the drachm in their own country.

We are informed both by Celsus and Pliny, that eighty-four *denarii* were coined out of the pound of silver; and therefore by determining the true weight of the Roman pound, we shall obtain that of the *denarius*, which depended upon it. Celsus de Medicina, lib. v. cap. 17. Pliny, Nat. Hist. lib. xxxiii. cap. 9.

If we take 6040 troy grains for the weight of the Roman pound, as determined from the gold coins, the consular *denarius* of 84 in the pound will weigh just 60 troy grains. Mr. Raper took the mean weight of forty-six of the fairest *denarii* in the British Museum, and found it to be 60.95 troy grains; but as some of these were imperfect, he found the mean of twenty perfect *denarii* to amount to 60.91; and he questions whether the *denarii* of above sixty-three grains ever passed as current coin. The weight of the *denarius* was diminished under the emperors; and Greaves found, by examining many imperial *denarii*, that from Augustus's time to Vespasian they continually almost decreased, till, from being the seventh part of the Roman ounce, they came now to be the eighth part; and ninety six were coined out of the Roman libra, whereas under the consuls they coined only eighty-four. Under Severus and Gordianus they recovered their weight, but with a considerable mixture of alloy. J. Calpar Effenichmid of Stralburg, in a book De Pondicibus & Mensuris veterum, &c. published in 1708, informs us, that he found the weight of the imperial *denarius* from Nero to Sept. Severus, to be to the consular *denarius* in the proportion of 7 to 8.

In order to determine the value of the consular *denarius* of 60 troy grains of fine silver, we are to consider, that sixty-two English shillings are coined out of eleven ounces two penny weight, troy, of fine silver, and eighteen penny weight alloy; and therefore the troy grain of fine

silver is worth $\frac{1}{15}$ ths of a farthing; and sixty grains, or the *denarius*, worth somewhat more than eight pence farthing and a half sterling; and the 95, or sixteenth part of the *denarius*, a little more than a half-penny. Phil. Trans. vol. lxi. part ii. art. 48.

Others, as Greaves, and after him Arbuthnot, have made the confular *denarius* the seventh part of an ounce in weight, a little more than sixty-two grains, allowing 5256 troy grains to the Roman pound, and its value, allowing eight English grains to the silver penny, $\frac{1}{16}$ th of our money; and the imperial *denarius* the eighth part of an ounce, and worth about 6d. sterling.

M. Tillemont observes, that the *denarius* was held sufficient to keep a person handsomely for a day: and, upon the whole, seems to estimate, that it was equal to twelve French fous, or eleven English pence: but this estimate seems in excess more than the preceding does in defect.

The *denarius* continued to be the current silver money of the empire, till Constantine substituted the milliarensis in its stead. See Greaves's Discourse of the *Denarius*, in his works, by Dr. Birch, vol. i. p. 235. and Arbuthnot on Coins, p. 15. See MILLIARENSIS and POUND.

DENARIUS is also used, in our *Law-Book*, for an English penny.

Denarius Anglie, qui aemulator sterlingi, vulgusque sine torpore, pendebat 32 grana fermenti in media spica; & 20 denarii facient unciam; & 12 unciae facient libram. Stat. Ed. I. De mensuris.

DENARIUS *Diei denarii* *carreg-mony*; called also *argentum Dei*, by the French *deniers de Dieu*, and in some parts of our country *den*.

Ita quod neuter mercatorum ad illa contracta posse discedere, nisi refectum postquam denarius Dei inter personas contrahentes, datus fuerit & acceptus. Charti Eduardi I.

DENARIUS *virorum comitatus*, denoted a third part of the profits of county courts. When those courts had superior jurisdiction, before other courts were erected, two parts of the fines, and other profits belonging to them, were referred to the king, and a third part to the earl of the county. Paroch. Ant. 418.

DENARIUS *de caritate* were customary oblations made to cathedral churches charged upon parish priests; though at first they were but a gift of charity for maintaining and adorning the bishop's see.

DENARIUS *de Patri*. See PETER-PENCE.

DENATES, in *Antiquity*, domestic gods, more frequently called *DESTATES*.

DENCHE', **DENCHLA**, or **ENBENCH'**, in *Heraldry*. See **DANCHE'**.

DENDRITES, or **DENDRACHATES**, in *Natural History*, a sort of state or agate, whereon are seen trees, shrubs, and other rural figures; represented, in miniature, in blackish or yellowish figures; now called *Mochoa* stones. Some rank the *dendritis* in the class of entochia, which they wrongly call stone plants; but against this it is urged, first, that the branches of trees, &c. represented on the *dendritis*, are never confounded together, nor shoot across each other, as those of entochia are usually found to do.

Secondly, that the fire strips the *dendritis* of all its figures, without destroying the stone, or reducing it to ashes; which does not hold of any entochia. See Tab. Fissil, Class 5.

Their true history is no more than this: the stone, or state, on which the *dendritis* most frequently occur, is soluble, like our common flints, to imperceptible cracks and flaws, into which the steams and effluvia from minerals, and other fossil bodies, continually pervading the whole structure of the earth, find their way, and perhaps in some cases water itself has been at some time in them: either water or these vapours, we well know, may be naturally enough tinged with black, or capable of leaving a black tinge on the surfaces of the bodies they have long remained on; and these finding their way into the natural cracks or small crevices of the stone, have from the sides of these insinuated themselves farther and farther into the mass, and run into branched figures; or the water wherever included has, as the mass of the stone shrank and contracted in the drying, spread and diffused itself into the various detached figures we see; for all the delineations we find in these stones may be referred either to these loose detached figures or cloudy spots, or to those which evidently arise from the sides of some loose cracks or fissures.

That water is continually to this day getting into these natural crevices of stone, and diffusing itself beyond their natural limits in irregular, and often in beautifully branched figures, we see in many of our gravel-pits, where many of the larger flints and pebbles being struck easily fall to pieces at these crevices, the sides of which are always either wet, or plainly marked with waters

having been once there; and if from these we trace the lesser cracks, we shall usually find numbers of figures imperfectly resembling the delineations in the agates, and the very same often also on their surfaces, merely the effect of mineral effluvia.

From hence it appears, that the figures of the *dendritis* are accidental: and the effect of a colour applied on the stone not artificially, but by nature. Two polished marbles being applied on each other, with oil between, upon parting them again, the oil running into certain tracks, its impression exhibits divers figures like those on the *dendritis*; the ramification always beginning on the side on which the marbles are began to be separated. So that it appears, the figures of the *dendritis* are formed by some bituminous, vitreous, ferruginous, or cupreous exhalation, insinuating between the beds or strata, and the stones; and, accordingly, we actually find, that the *dendritis* being exposed to the fire, yields a bituminous smell; and other experiments prove the existence of the other mineral principles.

In some *dendritis*, the figures, or figuratures, penetrate quite through; in others they go but to the middle; and, in others, not so deep.

On the surfaces of the natural crevices of our septaria, or ludus Helmontii of the harder kinds, we often also meet with what authors call *dendritis*, or fuliginous delineations of trees, which are of the very same kind with those of this agate, and are so far from being inferior to them in beauty, that they even greatly excel their rivals, so low and poor a substance as common chalk is not without them, but is frequently found beautifully marked with branches, trees, stars, and a thousand other figures like those formed by pulling asunder two levigating stones with the fine matter between them, or the shooting of salts in chemical vessels, or the figures of hoar-frost on our windows. Da Costa's Hist. of Foss. p. 178. Hill's Hist. of Foss. p. 473. See AGATE.

DENDRANATOMY, from *dendron*, tree, and *anatomia*, anatomy, a term used by Malpighi, and others, to express the dissection of the ligneous parts of trees and shrubs, in order to the examination of their structure and uses. Galen has used the same word, and taken some pains to discover some of the subjects of these researches. There is a very remarkable analogy between the parts of some trees, and those of peculiar parts of animal bodies; and Malpighi has, with great justice, used the comparative anatomy of trees, to explain by the formation of the galls, and other preternatural tumours in them, the pustules and other unnatural fleshy excrescences on animal bodies.

DENDROMETER, from *dendron*, a tree, and *metron*, I measure, an instrument lately invented by Messrs. Duncombe and Whittell, for which they obtained a patent, so called from its use in measuring trees. This instrument (Tab. II. Surveying, fig. 39.) consists of a semicircle A, divided into two quadrants, and graduated from the middle; upon the diameter B there hangs a plummet L for fixing the instrument in a vertical position; there is also a chord D parallel to the diameter, and a radius E, passing at right angles through the diameter and chord. From a point on the radius hangs an altimeter C, between the chord and diameter, to which is fixed a small semicircle G, and a screw to confine it in any position. The altimeter, which is contrived to form the same angle with the radius of the instrument as the tree forms with the horizon, is divided from its centre both ways into forty equal parts; and these parts are again subdivided into halves and quarters. Upon the small semicircle G, on which is accounted the quantity of the angle made by the altimeter and radius, are expressed degrees from 60 to 120, being 30 on each quadrant. The radius is numbered with the same scale of divisions as the altimeter. There is also a nothus to the small semicircle, which shows the quantity of an angle to every five minutes. On the back of the instrument the flock M (fig. 40.) of the sliding-piece is confined to the axis N, which moves concentrically parallel to the elevation index F (fig. 39.) on the opposite side, to which it is fixed. This index is numbered by a scale of equal divisions with the altimeter and radius: at the end of the index is a nothus, by which the angles of elevation above, or of depression below the horizon, measured upon the semicircle of the instrument, are determined to every five minutes. There is also a groove in the radius, that slides across the axis by means of a screw I, working between the chord and semicircle of the instrument, and this screw is turned by the key O. Upon the flock M (fig. 40.) is a sliding piece P, that always sits at right angles with the altimeter, by means of a groove in the latter. To the flank of the sliding piece is annexed a moveable limb Q, which forms the same angle with the altimeter as the bough forms with the body, or trunk of the tree. This limb

limb may be of any convenient length, divided into equal parts of the same scale with all the foregoing divisions. At the extremity of the fixed axis, on a centre, an index R, with telescopic sights, works horizontally upon the movable limb of the sliding piece. Upon this horizontal index R may be fixed a small quadrant T, described with any convenient radius from the centre on which the index moves, and divided into 90 degrees, beginning at a right line drawn from the centre at right angles with the fiducial edge of the said index; and upon the extremity of the axis is a nonius, whereby to determine the quantity of an angle upon the quadrant to every five minutes. There are also two small circular arches S, S, serving to keep the sights in a parallel position, each containing an equal number of degrees. Upon these arches is measured the angle, subtending a side equal to the difference of the altitudes of the observed objects above the plane of the horizon, and whose base is the nearest distance between the perpendiculars, in which these objects are situated. The *dendrometer* is fitted to a theodolite, and may be used either with or without it, as occasion requires.

The principal use of this instrument is for measuring the length and diameter of any tree, perpendicular or oblique, to an horizontal plane, or in any situation of the plane on which it rests, or of any figure, whether regular or irregular, and also the length and diameter of the boughs, by mere inspection; and the inventors of it have calculated tables, annexed to their account of the instrument itself, by the help of which the quantity of timber in any tree is obtained without calculation, or the use of the sliding rule. The instrument is rectified by setting it in a perpendicular position, by means of the plummet, and screwing it to the staff; then the altimeter is placed in the exact position of the tree, whether perpendicular, reclining, or inclining, and screwed fast. If the tree stands on level ground, the horizontal distance from the tree to the axis of the instrument is measured with a tape line, and the radius is moved with the key, till that distance be cut upon it by the inside of the diameter; but if the ground be sloping, the distance from the tree to the instrument is measured, and the elevation index is moved, till the point of the tree from which the distance was measured is seen through the sights, and there screwed fast; and the radius is moved backwards or forwards with the key, till this distance is cut upon the elevation index by the perpendicular line of the altimeter; and the horizontal line will be marked upon the radius by the inside of the diameter. In order to obtain the length of the tree, the elevation index is first moved downwards, till the bottom of the tree cut by the horizontal wires is observed through the sights, and the feet and inches marked by the index upon the altimeter below the point of sight, or horizontal line, are noted down: then the index is moved upwards, till the part to which you would measure, cut by the horizontal wires, is seen, and the feet and inches marked on the altimeter above the point of sight, are noted: these two quantities added together give the exact length of the tree, which is inscribed in a field-book.

For the girth of the tree, the circumference in that part where the horizontal distance was taken, is measured with the tape line; and a sixth part of this circumference is added to the distance on the radius, which was before cut by the inside of the diameter, because the tape-line, in taking the distance, cannot be applied to the centre of the body of the tree; then the elevation index is lowered to that part of the tree, of which the diameter is to be taken and screwed fast. Set the movable limb of the sliding piece quite straight, and the edge of the horizontal index upon the first division of it. Turn the whole instrument about to the left hand, till you see, through the sights, the left side of the tree cut exactly by the perpendicular wires; then, the instrument being fixed, move the sights only upon the sliding piece, till you see the right side of the tree cut also by the perpendicular wires, and you will find the true diameter marked by the horizontal index upon the sliding piece, which is to be entered in a distinct column of the field-book.

For the boughs: let the distance on the radius be now reduced to its former quantity, and the elevation index moved upwards, till the bough is seen through the sights, and screwed fast: set the movable part of the sliding piece in a position parallel to the bough, and the edge of the horizontal index on the first division of it. Turn the whole instrument about, till you see, through the sights, the shoot of the bough, close to the trunk cut by the perpendicular wires; then move the sights, till you see the other end of the bough cut by the said wires, and note the feet and inches marked by the horizontal index on the movable limb of the sliding piece, which will give the true length of the bough, to be in-

serted in the field-book. And the girth of the bough may be obtained, by directing the sights to that part of it, whose girth is desired; then by moving the elevation index downward, till you see the under side of the bough cut by the horizontal wires; and there noting the feet and inches marked by the said index on the altimeter: after which, let the elevation index be moved upwards, till the upper-side of the bough cut by the horizontal wires is seen; the feet and inches marked upon the altimeter are to be noted as before: the former quantity subtracted from the latter will give the true diameter of the bough, which is entered in the field-book. The true solidity both of the body of the tree, and of the boughs, may be found from the diameter and lengths in tables calculated for this purpose.

The *dendrometer*, fitted to a theodolite, may be applied to measuring the heights and distances of objects, accessible or inaccessible, whether situated in planes parallel, or oblique, to the plane in which the instrument is placed. It may be also used for taking all angles, whether vertical, horizontal, or oblique, in any position of the planes in which they are formed; and thus for facilitating the practical operations of engineering, land-surveying, levelling, mining, &c. and for performing the various cases of plane trigonometry, without calculation; of which the inventors have subjected to their account of this instrument many examples. See a Treatise upon the *Dendrometer*.

DENDROPHORIA, in *Antiquity*, the carrying of one, or more, trees, in ceremony, through a city, at certain feasts, and in honour of certain deities.

The word is formed of *δένδρον*, tree, and *φορᾶ*, I bear.

The *dendrophoria* was performed at the sacrifices of Bacchus, Cybele, and the god Sylvanus. Arnobius, lib. v. makes mention of that performed in the sacrifices of the mother of the gods. It consisted in carrying a pine in procession through the city, which pine was afterwards planted in memory of that under which Atyr, the favourite of this goddess, mutilated himself. The branches of this tree they crowns, in memory of Cybele's doing the same; and they covered its trunk with wool, because the goddess covered Atyr's breast with the same matter.

The persons who performed the office of carrying the tree were called *dendrophori*.

In the Roman history we find mention made of a company, or college of *dendrophori*, who attended the army; and the critics have laboured much to assign their office. Some hold, that they bearded and fashioned the wood for the tents; others, that they provided the wood necessary for the military works, machines of war, &c. Salmasius, in his notes on the Life of Caracalla by Spartian, owns this to be the general opinion of all the learned men of his time; but assures us, that they were all mistaken, and that the *dendrophori* of the army were the same with those of the feasts and sacrifices.

DENEB, an Arabic term, signifying *tail*, used by astronomers as a denomination of several fixed stars.

Thus *deneb eliet* signifies the bright star in the lion's tail; *deneb adige*, that in the swan's tail, &c.

DENEB, or **ALDINES Akabli**, in the *Writings of the Arabian Physicians*, the name of the equisetum or horse-tail: there is, however, no great dependence to be had on what authors say of this plant.

DENIER, the French penny; a small copper coin; twelve whereof make a sol, or French shilling.

The French *denier* is now about the twenty-third part of the English penny. It is subdivided into two mailles, and the maille into two oboles. Anciently *denier* was a general name for all sort of monies in France; as *nummus* for those of Rome. Thus, a piece of gold money was called *denier d'or*; silver money, *denier d'argent*; after the same manner as the Romans said *nummus aureus*, and *nummus argenteus*.

There are two kinds of *deniers*; the one *Tournois*, the other *Paris*; whereof the latter was worth a fourth part more than the former, and was called *monnaie royale*, or *forte monnaie*, and sometimes *denier d'or*, and *denier à valleur d'or*. See **MONEY**, &c.

There are at present in France several little copper pieces, which having no proper name, are distinguished only by their value in *deniers*: such are the pieces of 36, 30, 24, 18, 12, 6, 4, and 2 *deniers*. The pieces of 4 and 2 *deniers* were coined at Stralsburg for currency in the province of Alsace, pursuant to the declaration of Sept. 6, 1695. Those of six *deniers* were coined in the mints of Aix, Montpellier, Rochelle, Bourdeaux, and Nantz; by the edict of 1709, and are little current. **Post. Dist. Comm.**

DENIZEN, from the British *disinshyden*, *man of the city*, or *denysyd*, free of the city, in *Levo*, an alien enfranchised in England by the king's letters-patent, and donation; —

and thereby enabled, in many respects, to do as the king's native subjects do; namely, to purchase, possess, and devise lands, &c.

Denization is a right inferior to naturalization by parliament: for a stranger naturalized may inherit lands by descent, which a *denizen* cannot. Neither can his issue, born before *denization*, inherit to him; but his issue, born after may. No *denizen* can be of the privy-council, or either house of parliament, or have any office of trust civil or military, or be capable of any grant from the crown. Stat. 12 Will. III. cap. 2.

Add, that, in the charter, whereby a person is made a *denizen*, there is usually some clause or other, which abridges him of that full benefit which natural subjects enjoy.

When a man is thus enfranchised, he is said to be, *ad fidem regis Angliæ*, or, under the king's protection; till such time his goods might be seized to the king's use.

DENOMINATION, from *denomino*, of *de* and *nomen*, a name, a name imposed on any thing, usually expressing some quality predominant therein.

Hence, as the qualities and forms of things are of two kinds, viz. internal and external, *denomination* becomes twofold.

DENOMINATION, internal, is that founded on the intrinsic form: thus Peter is *denominated* learned, on account of his learning, which is something internal.

DENOMINATION, external, is that founded on, or arising from the external form. Thus, a wall is said to be seen, and known, from the vision and cognition employed upon it; and thus Peter is *denominated* honoured, by reason of honour, which is not in the person honoured, but in him that honours.

DENOMINATOR, in *Arithmetic*, a term only used in speaking of fractions, or broken numbers. See **FRACTION**.

The *denominator* of a fraction is the number or letter below the line; shewing into how many parts the integer is supposed to be divided by the fraction.

Thus in the fraction $\frac{7}{12}$; seven twelfths, the number 12 is the *denominator*, and means, that the integer is here divided in 12 parts. So in the fraction $\frac{a}{b}$, *b* is the *denominator*.

The *denominator* always represents an integer. The number above the line, *a*, is called the *numerator*.

DENOMINATOR of a ratio is the quotient arising from the division of the antecedent by the consequent.

Thus 6 is the *denominator* of the ratio 30 : 5, because 5) 30 (6. The *denominator* is what we otherwise call the *exponent* of the ratio.

DE NON RESIDENTIA clerici regis, in *Law*, the name of an ancient writ, the form whereof fee 2 Inlt. fol. 624. for excusing a parson employed in the king's service for non-residence.

DENS cavi, in *Botany*. See **DOG'S TOOTH**.

DENSIFYING of land, in *Agriculture*, is the casting parings of earth, turf, and stubble, into heaps, which when dried are burnt to ashes, for a compost on poor barren land. This method of improvement is used, on taking in and enclosing common waste grounds. In many parts of England this is called *burn-beating*; but in Staffordshire, and other counties, they term it *densifying* of land. See **BURNING of land**.

DENSITY, *Densitas*, that property, or habitude of bodies whereby they contain such a quantity of matter, under such a bulk.

Accordingly, a body that contains more matter than another, under the same bulk, is said to be *denser* than the other.

Density stands in opposition to *rarity*. Hence, since the mass is proportional to the gravity, a *denser* body is specifically heavier than a *rarer*; and a specifically heavier is *denser* than a specifically lighter.

The *densities*, and bulks of bodies, are the two great points, whereon all mechanics, or laws of motion, turn: it is an axiom, that bodies of the same *density* contain equal masses under equal bulks. If the bulks of two bodies be equal, their *densities* are as their masses: consequently the *densities* of equal bodies are as their gravities. If two bodies have the same *density*, their masses are as their bulks: and hence, the gravities of bodies of the same *density* are in the ratio of their bulks. The masses of two bodies are in a ratio compounded of their *densities* and bulks; consequently, their gravities are in the same ratio; and if their masses or gravities be equal, their *densities* are reciprocally as their bulks. The *densities* of any two bodies are in a ratio compounded of the direct ratio of their masses, and the reciprocal one of their bulks. Thus, let *D* represent the *density*, *M* the magnitude or bulk, and *Q* the mass or weight of one body; and *a*, *m*, *q*, those

respectively of another: then we shall have $D = \frac{Q}{M}$ and $d = \frac{q}{m}$, and therefore $D : d :: \frac{Q}{M} : \frac{q}{m}$; and $D M q$

$= Q m d$; whence the preceding propositions may be easily deduced.

The Peripatetics define *density* a secondary quality, whereby a body is full of itself, its parts cohering without any interstice. So that the term of *density* consists in the immediate coherence of parts. Hence Porphyry in his Predicaments defines a *dense* body, that whose parts are placed so near each other, that no other body can come between them; as gold.

The efficient cause of *density* they usually attribute to cold. Scaliger and some others, attribute it to moisture. Many of the moderns take the smallness of the parts of bodies, to contribute much to their *density*; as by this means the pores are left the smaller: though it is added, that the *density* of bodies does not only depend on the smallness of the pores, but also on their *tenuity*: so far are we from having any body absolutely *dense* in the sense of the ancients, that gold itself, the *densest* and heaviest of all natural bodies, Sir Isaac Newton observes, contains a great deal more pore, or vacuity, than substance.

When the pressures of two liquids are equal, the quantities of matter in columns which have equal bases *do not differ*; wherefore the bulks, that is, the height of the columns, are inversely as the *densities*; whence may be deduced a method of comparing them together. For if in communicating tubes there be different fluids, and they remain at rest, their pressures are equal; and by measuring their altitudes, the ratio of their *densities* is found.

The *densities* of liquids are also compared together by immersing a solid into them: for if a solid lighter than the liquids to be compared together, be immersed successively into different liquids, the immersed parts will be inversely as the *densities* of the liquids. For, because the same solid is made use of, the portions of the different liquors, which in every case would fill the space taken up by the immersed parts, are of the same weight: therefore the bulks of these portions, that is, the immersed parts themselves, are inversely as the *densities*.

DENSITY of the air is a property that has much employed the later philosophers, since the discovery of the Torricellian experiment, and the air-pump.

It is demonstrated, that in the same vessel, or even in vessels communicating with each other, at the same distance from the centre, the air has every where the same *density*. The *density* of the air always increases in proportion to the compression, or the compelling powers.

And hence, the lower air is always *denser* than the upper; yet the *density* of the lower air is not proportional to the weight of the atmosphere, by reason of heat and cold, which make considerable alterations as to *rarity* and *density*. If the air be rendered *denser*, the weight of bodies therein is diminished; and if rarer, increased; because bodies lose more in heavier than in lighter mediums.

And hence, if the *density* of the air be sensibly altered, bodies equally heavy in a lighter air, if their specific gravities be considerably different, will have their equilibrium taken away in a *denser* air, and the specifically heavier will preponderate; which is the foundation of the MANOMETER, an instrument for measuring the alterations in the *density* of the air.

DENSITY of the planets; in homogeneous, unequal, spherical bodies, the gravities on their surfaces are as their diameters, if the *densities* are equal. But if the bodies be equal, the gravities will be as the *densities*. Therefore in bodies of unequal bulks and *densities*, the gravity will be in a compound ratio of the diameters and *densities*; consequently the *densities* will be as the gravities divided by the diameters, and therefore in the several bodies as follows, viz.

In the Sun.	Jupiter.	Saturn.	Earth.	Moon.
10000	9385	6567	39539	48911
Or 25½	19	15	100	123½

As it is not likely that these bodies are homogeneous, the *densities* here determined are not supposed to be true; but rather the mean *densities*, or such as the bodies would have if they were homogeneous, and of the same mass of matter and magnitude.

DENTAL, DENTALIS, from *dens*, a tooth, is applied to certain letters, in the pronunciation whereof the teeth have a principal share.

Grammarians, and especially the Hebrew ones, distinguish the letters into *dental*, *labial*, *gutturæ*, *lingual*, *palatal*, &c.

DENTALIS, or DENTALIUM, is a kind of unguine shell, which the apothecaries are ordered to pulverize, and use in several medicaments, as an alkali.

The genuine *dentula*, described by M. Tournesort, is of a tubular, or conical form, about three inches long; of a shining, greenish-white colour; hollow, light, and divided lengthwise by parallel lines running from top to bottom. It is about the thickness of a quill, and bears some resemblance to a dog's tooth, whence its name.

The *dentulum* is a genus of the *testina* worms, in the Linnean system. It is very scarce; and therefore, in lieu of it, they usually substitute a shell of divers colours found among the sand when the sea is withdrawn; but not channelled, or fluted, like the *dentula*.

Dr. Lister, in the Philosophical Transactions, makes mention of two species of *dentula*; the first commonly enough found about the island of Guernsey, &c. being a long, slender, white pipe, a little bending and tapering, and open at both ends; the other, properly called *equilum*, longer and thicker than the former; and besides, streaked with ridges; whence the Italian term *istigla*. See Tab. III. of *Fossils*, Class 9. See ENTALUM.

There are two principal kinds of them, the one smooth, the others striated. Of the smooth kind, some are all over white, others are tipped with red at the end; and of the striated ones, some are altogether white, others are green, and in some the stripes are more prominent, in others fainter, especially in the lesser ones. See Tab. of *Shells*, N. 4.

This shell is also called *dentulum* and *springer*. Taken inwardly, it is used as an alkali to sweeten acids, to stop a looseness of the belly, and for spitting of blood. It is also used externally as a drier.

DENTALIUM. See the preceding article.

DENTARIA, in Botany. See TOOTH-WORT.

DENTATED Leaf, in Botany. See LEAF.

DENT ED, indented, toothed. See INDENTED.

DANTED verge, among Botanists, is applied to such leaves of plants as are notched, or jagged about the edge or rim; of these some are *fine-dent*; others *large*, or *deep dent*, i. e. cut into the leaf. See LEAF.

DANTED wheel, *rota dentata*. See WHEEL.

DENTES, in Anatomy. See TEETH.

DENTEX, in Ichthyology, the name of a sea-fish, caught in great plenty in the Mediterranean, and common in the markets of Italy. See SYNGDON.

It is a well-tailed fish, and is caught of five, or six, and sometimes ten pounds weight; it is somewhat broad and flat in its shape, yet considerably thick and long. Its head is flattened, its snout very long, and its back edged and sharp; its back and sides are of a dusky yellowish green colour, and sometimes, in the full grown fish, purplish, always spotted with very bright blue and black spots; the back and gill-fins have each a black spot near their origin, and their belly-fins are yellow.

The teeth are disposed in a single row in each jaw, and there are at distances four, which are longer and broader than the rest, and look like the canine teeth of men, or of quadrupeds: it is from these that it has its name, and these as well as the rest of the teeth are in this fish covered with lips, as in quadrupeds; its tail is forked, and its scales are very large. GEFROT.

DENTICLES, or DENTILI, in Architecture, an ornament in cornices, bearing some resemblance to teeth; particularly affected in the Ionic and Corinthian orders; and of late also in the Doric.

They are cut on a little square member, properly called *dentulus*; and the notches, or ornaments, themselves, *dentili*; by the Italians, *dentilli*, and *dentigli*, from *dens*, tooth, as having the appearance of a set of teeth.

Anciently *dentili* were scarce ever used but in the Ionic cornice; yet we find them in the remains of the theatre of Marcellus; and this is an argument with some, that Vitruvius had not the direction of that building. Vitruvius prescribes the breadth of each *dentil*, or tooth, to be half its height; and the metopa, or interval between each two, he orders to be two-thirds of the breadth of the *dentil*, lib. iii. cap. 4.

The same author, cap. ii. of his fourth book, observes, that the Greeks never used *dentili* underneath modillions, because modillions represent pedims, and *dentili* represent ends of rafters, which can never be placed underneath pedims.

The Romans were not so scrupulous as to this decorum; excepting in the Pantheon, where there are no *dentili* under the modillions, neither in the portico, nor in the inside of the building.

DENTICULA Elephantis, in the History of Shells, a name given by many authors to the *dentula*, a small shell of the tubular marine kind, which is somewhat bent and pointed at one end, and in some measure represents the elephant's tusk. See DENTILIA.

DENTIFORMIS præputii, the same as PYRENOIDES.

DENTRIFICE, from *dens*, a tooth, and *fric*, I rub, in Me-

dicus, tooth-powder; a remedy to rub the teeth, in order to cleanse, or soften them.

There are *dentrifices*, of divers kinds and various time in form of a powder, composed of corals, rumex-flam, fls, alum, egg-shells, crab-claws, hartshorn, cuttle-bone, urinar striated, &c. Others in form of an electuary, consisting of the same powders mixed up with honey.

There are others, prepared with roots boiled with alum, and dried in the oven. Others in form of a liquor, drawn by distillations from drying herbs, and astringent medicines.

The Dutch hold butter the best *dentrificer*, to keep the teeth white and sound; and the Spaniards, urine.

The generality of operators for the teeth allow acids, such as spirit of vitriol, &c. to be the residuum of all *dentrifices*, to take off the foulness and yellowness of the teeth; but though they allow that these render them white, for the present, they discountenance a frequent use of them, as wearing away too much of the teeth, and injuring the gums.

Tachenius attacks spirit of vitriol even in a stronger manner, and affirms that it cannot answer the full purpose of making the teeth whiter; he alleges, that the mixture of spirit of vitriol, with any white shell, produces a yellowish colour, not a white one. It is evident that our sweat, and all other matter, transpiring through the pores, is of an alkaline nature, and there continually transpires through the gums something of this kind, which lodging itself upon the teeth, must needs mix with the remains of the spirit of vitriol left on them in the cleaning; and, by that means, the whiteness at first given will gradually go off; and the yellow, which is the natural result of an alkali, with spirit of vitriol, will appear in its place. Tachenii Hippocrat. Clym.

DENTIL, in Architecture. See DENTICLES.

DENTILLARIA, in Botany, a name by which some authors call the *plumbago*, or LEAD-WORT.

DENTISCALPRA, from *dens*, tooth, and *scalpra*, scraping instrument, in Surgery, an instrument for scraping yellow, livid, or black teeth; to which being applied near the gums, it scrapes off the foul morbid crust. Some of these instruments are furnished with narrow points; others with broader, and with edges; and some again are falciform; but all of them adapted to one and the same handle.

DENTITION, *Dentis*, the act of breeding or cutting the teeth.

The time of *dentition*, is usually from about the sixth or seventh month to the age of twenty. The *infans* come first; then the *canini*; after them the *molars*; so that at the end of the second year, in general, a child is furnished with ten teeth in each jaw, called the milk-teeth; this is the first *dentition*. These generally last till the sixth or seventh year, when they fall successively without any considerable pain, and are succeeded by others, till the fourteenth or fifteenth year. The seventh year is usually the period of the second *dentition*; it often happens at this period, says an ingenious dentist, Mr. Magens, that the roots of the milk-teeth are too firmly fixed, to give way to the progressive growth of the succeeding ones, which are in a soft feeble state, and incapable of forcing their way in a proper order. In this case the new teeth become indented, and otherwise deformed; and by forcing their way on either side of the milk-teeth, form a double row, and assume the appearance of supernumerary teeth; and besides, the root of the milk-teeth is sometimes united in the socket with the root of the adult tooth, thus forming one root with two distinct teeth in the crown; in consequence of which, the partitions of the sockets are immoderately distended and weakened, and become incapable of retaining the famina in their distinct alveoli or sockets. It will therefore require peculiar attention, to determine when an extraction of the milk-teeth is necessary, whether they be fast or loose in their sockets, in order to insure a quicker growth, and a beneficial arrangement of the succeeding set. This second *dentition* produces the four first great *dentis molares*, one at either extremity of both jaws; and from the tenth to the fifteenth year a third *dentition* happens, which furnishes four other great *molars*, one clove by each of the former. The *molars* of the seventh year are subject to a caries and early decay, which is sometimes attended with violent inflammations, tumors, and ulcerations of the gums. When these symptoms appear, and before the ulcer corrodes deeply, it will be necessary to extract the tooth, which will commonly remove these dreadful symptoms. It has been observed, that in some cases the increased size of the *molars* forces and distends the lower jaw beyond its proper place, so that the lower teeth project as they approach the upper ones; and a timely extraction of the two great grinders in the lower

jaw, whether they are decayed or not, has been recommended for preventing this deformity. About the twentieth year comes the last *dentition*, which gives the four extreme *dentes molares*, called *dentes sapientia*, because they come after puberty.

Dentition, Hippocrates observes, is usually preceded with an itching of the gums, and with convulsions, fevers, and looseness; especially when the canine teeth are cut. Most of these symptoms Dr. Lister, on this passage of Hippocrates, observes, happen to birds upon moulting, or casting their feathers; on which occasion also they become mute, and fallow.

The germen, or seed of the tooth, says Dolzeus, is a tender mucous matter, like the white of an egg, contained in the cells, or alveoli, of the jaw-bone, which grows harder and bigger every day, till it be fit to break through the gum. In this rupture the poor child is afflicted with terrible symptoms, inflammations of the jaws, gripes, waking, inquietude, terrors, dejections, vomiting, salivation, epilepsy, abscesses, and frequently death.

There are two terms, or periods of *dentition*; the one, when the tooth makes its first endeavour to get out of the maxillary bone, and wherein the outer and upper part of the gum rises to be encompassed with a whitish circle; the other, when the tooth, considerably enlarged in bulk, renders the gum tumid, and strives with all its force to break its way through the fame. The remedies against the symptoms of *dentition* are absorbents, and gentle purgatives.

If the fever be high, bleeding will be necessary: though this is an evacuation which children bear the worst of any. Sydenham says, that in fevers occasioned by *dentition*, he never found any remedy so effectual, as two, three, or four drops of spirit of hartshorn, in a spoonful of simple water, given every four hours. It may be given from five drops to fifteen or twenty, according to the age of the child; and when coarctation does not forbid it, three or four drops of laudanum may be added to each dose. In convulsion fits, a blistering plaster may be applied betwixt the shoulders, or one behind each ear. A small Burgundy pitch plaster between the shoulders has been sometimes applied, when children are cutting their teeth; and has been found to ease the tickling cough which attends teething. The gums may be rubbed with a little fine honey three or four times a day: and children should be always supplied with something that will yield a little to the pressure of their gums, as a crust of bread, a wax-candle, a bit of liquorice-root, &c. Cutting the gums is seldom of any use; however, in obstinate cases it ought to be tried. The food of children should at this time be light, and their nerves braced by sufficient exercise without doors, the use of the cold bath, &c. With these precautions, there would be little occasion for teething necklaces, and other absurd amulets, which are often worn, under the notion of aiding *dentition*.

DENUATION, from *de*, and *nudus*, naked. See EXPOSITION.

DENUNCIATION, *Denunciatio*, a solemn publication, or promulgation of any thing.

All vessels of enemies are lawful prize after *denunciation*, or proclamation of war.

The design of the *denunciation* of excommunicated persons is, that the sentence may be the more fully executed; that the persons may be known, the entrance into the church refused them, and that other people may be warned not to have any communication with them.

DEOBSTRUENTS, from *de*, and *obstruo*, I obstruct, are such medicines as open obstructions.

There is something farther intimated by *deobstruent* than by *detergent*: for a medicine may be *deobstruent*, that is not in the strictest sense *detergent*: as, in effect, are most of those which are made of metalline substances, such as steel and mercury: which obtain the appellation *deobstruents* from their acting by their natural weight, whereby they increase the momentum of the circulating fluid, and make it strike against the secretory outlets with greater force, because the momentum, or vis perculsiva, of all projectiles, of which kind is a circulating fluid, is as their solidities, supposing their velocities equal. The more, therefore, the animal fluids are saturated with dense and solid particles, with the greater force they distend the vessels, and the more easily break through, where the structure favours their escape; and upon that account are medicines which add to these qualities in the fluids called *deobstruents*.

DEODAND, in our *Customs*, a thing given, or forfeited, as it were, to God, for the pacification of his wrath in a case of misadventure, whereby a man or woman comes to a violent end, without the fault of any reasonable creature.

As, if a horse strike his keeper, and kill him; if a man in driving a cart falls, so that the cart-wheel runs over him, and presses him to death; if one be felling a tree, and gives warning to the standers by, to take care of themselves, yet a man is killed by the fall thereof: in the first place, the horse; in the second, the cart-wheel, or the cart and horse; and in the third, the tree; *Deo dandus*, to be given to God, that is, to the king, to be distributed to the poor by his almoner, for expiation of this unhappy event; though effected by uncreational creatures, or inanimate substances.

Omnia quae moriuntur ad mortem sunt dandenda.

What moves to death
Is dandend.

This law seems to be an imitation of that in Exodus, chap. xxi. *If an ox gore a man, or a woman, with his horn, so that he die, the ox shall be stoned to death, and his flesh not be eat; so shall his owner be innocent.*

Fleta says, the *deodand* is to be sold, and the price distributed to the poor, for the soul of the king, his ancestors, and all faithful people deprived this life.

It was originally designed, in the superstitious times of popery, as an expiation for the souls of such as were snatched away by death; and was given to the church in order to procure the soul of such deceased person to be prayed out of purgatory.

DEONERANDO *pro rata portione*, in the law of England, a writ that lies where one is distrained for a rent that is to be paid proportionably by others: thus, if a man holds ten acres of land by fealty, and ten shillings rent, of the king; and aliens, one acre to one, and another to another, in fee; and afterwards the sheriff distrains only one of them for the rent; he that is so distrained may have his writ for this relief.

DEOPIPLATIVE, from *de*, and *opilio*, I obstruct, a remedy proper to soften, resolve, and remove obstructions. See OBSTRUCTION.

Deopiplative are the same with what we otherwise call *deobstruents*. See DEOBSTRUENT.

DEOSULATION, *Deosulatio*, in *Antiquity*, one of the most ancient forms of ADORATION.

DEPART, a method of refining, or separating gold from silver by means of *aqua fortis*.

There are three ways of refining gold: the first by antimony, the second by sublimate; and the third, which is the most usual, by *aqua fortis*. The two former, see under REFINING.

For the operation of the *depart*, they take at the rate of one pound of impure gold, and two or three of silver; these they fuse together in a crucible, and, when fused, cast them into cold water, where they become divided into grains of the bigness of peas. These grains taken out, and dried by the fire, are put in a *deposing* vessel, which is a stone matrix, and to the metal are added four pounds of *aqua fortis*. Then taking the vessel, they set it on the coals, and in about an hour's space the refining is done. For, upon opening the vessel, they find nothing appear therein but the *aqua fortis* and the gold reduced into a calx, or sand; the silver being all dissolved, and imbibed by the liquor.

To raise the gold to its due fineness, they usually give it the *aqua fortis* again and again; using for the first time half a pound, and for the second a quarter of a pound of the water, to eight ounces of metal. If the third water be found good and clear the operation is ended: and the calx of the gold, being washed in repeated waters, is melted down again in a crucible, first by a gentle, and afterwards a vehement fire, to be cast into ingots, or wedges.

It must be added, that the silver, with the impurities of the gold, is so thoroughly incorporated with the water, that to the eye there does not appear any thing beside the pure liquid; yet is not this silver lost. To recover it again out of the menstruum, they divide their flock of *aqua fortis* into several stone vessels, which they fill up with spring water, observing to put seven or eight times as much of this, as that. This done, in each vessel they put a quantity of copper; and leaving the whole for twenty-four hours, at the end thereof they find the spirits of the *aqua fortis* have quitted the silver, and are with the copper, leaving the former in form of a calx, or incorporated ather at bottom. This calx, being dried, is melted into an ingot, with a little salt-petre.

To husband the *aqua fortis*, and make it serve again for a second operation, they dilute it in an earthen, or glass alembic; and when the distillation is about a third over, change the recipient. The water of the first recipient serves for the first operation of *departing*, and the rest for the subsequent ones.

If the *aqua fortis*, having quitted the silver, and being united with the copper, be then filtrated, it is called *aqua secunda*; in which if you steep an iron plate some hours,

are said to *depress* the pole, because it becomes, respectively, so much lower, or nearer to the horizon.

pression of the visible horizon, depends on sinking or rising below the true horizontal plane, whether caused by some variation of the atmosphere, or by the different height of the observer's eye above the surface of the sea. Thus, let AS' (Fig. 11. *Surrounding*, p. 38.) be the surface of the sea, EA the height of the eye above that surface, and AT the observer's horizon; then the eye looking along EA for the horizon, which dips below the true one by the arc EA , perceives the apparent altitude AT of an object, measured by the arc AT ; but if the observer has his back towards the object T , then looking along the line ET , the apparent horizon now becoming the line ET , and dipping below the true one by the arc ET , he will find the apparent altitude ET is a little, and must be augmented by the arc EA ET . The *depression* or dip of the horizon may be easily computed, thus, let C be the earth's center, E the eye, and T the tangent ET meeting the surface in T , where the eye and water seem to meet; then the CET is a triangle, right angled at T , where CE is the distance CE = $\sqrt{R^2 + CE^2}$ = the distance from the earth's focus to center, and CT = $\sqrt{R^2 + CE^2}$ the height of the eye added to the earth's radius; thus as CE and C are given, CT and ET whole complement to the angle ET , the dip height. The following table shows the *depression* or dip of the horizon of the sea for different heights of the eye, from one to a hundred feet.

Persons of the Age above the Age in Feet	Length of the bones of digits	Skullion, &c. Feet	Digitallion, &c.
1	0 87	22	4 28
2	1 11	24	4 40
3	1 30	26	4 52
4	1 55	28	5 3
5	2 8	30	5 14
6	2 20	35	5 30
7	2 31	40	6 8

20	4 16		

See Robertson's *Elem. of Navigation*, book ix. p. 391.
200 Tables requisite to be used with the Nautical Ephemeris, p. 745. See *LAYER TWO*.

Depth of the jaw, or of a star, is its distance from the horizon. Below it, measured by an arch of the visible circle, is indicated between it and the horizon.

was given by Galienus, in *Anatomy*, a name given by Albinus to a muscle of the face, called by Cooper *angulillar alae nasi*, and denominated *labii superioris*.

SPERMATOPHYTES, in *Botany*, a name given by Al. Brink to the inside called by others *Spermatophyta* (which see).

Сокращеніи и сиренит, is a muscle called *abductor pollicis*
 and m. See СОРАТНИКОВЫЙ м.

It is with this inferior process, or tendon, a muscle placed between the *depressor labiorum superioris*, on the part called the *ala*. It appears to be but one muscle, ascending with a rounded head of fleshy fibers, and terminating in the lower lip. Its office is drawn by its name, it depresses the lower lip. See *Takenout* (April) 1871.

Cartilagenous ligament, commonly, by some called *Apophyseal ligament*, and *triangularis*, is common to both lips. It arises with a broad origin from the lower margin of the under lip, by the side of the ship, and is inserted with a narrow end into each lip near their cushion, tending to draw them obliquely down. See *Tet. Lig.*

inserted into them, not unlike the sphincters of other

DEPRIMENS, in *Anatomy*, the same with DEPRESSOR.
DEPRIMENS *lingue*, in *Anatomy*, a name given by Savi-

line, and others, is one of the muscles of the lower jaw, called by others *Agglossus five dentatus*; and, by Albinus, *Alveolar muscle inferior*.

DEPARTMENT *humane vitium*, in *Anatomy*, a name given by Spigelius, and others, to a muscle called by others the *long* *major*, and *rotundo* *major*.

DEPUTATUS, ARMATARIUS, was also an inferior officer in the church of Constantinople, whose business was to

call persons of condition the patriarch had a right to speak with, and to keep off the crowd, where that priest walked.

This *deputy* appears to have been a sort of usher, or signifier; but he had likewise the care of the sacred vestments, in which he approached the office of a sacrificer.

DEPUTY, a person sent, or *deputed*, by some community, in their name and behalf.

The several provinces of the French dominions send *deputies* to the king every year, to present him the *cayes des états*; there are always three *deputies*, one from each order. It is the *deputy* of the first order that makes the compliment to the king. In the cities of Turkey there are always *deputies* to treat with the grand signior's officers, as to taxes, and other concerns. These *deputies* are three or four of the richest and most comfortable among the burghers.

DEPUTY is also frequently used among us for an officer, or employ, not a dignity, and usually indifferently for a vice, or lieutenant.

DEPUTY, in Law, is one who exercises an office in another's rights, and the full name or maintenance of such *deputy* shall cause the person whom he represents to lose his office. A principal officer may not appoint a *deputy* in all cases, unless the grant of the office will justify him in so doing; but when an office depends on an infant, idiot, &c. he may make a *deputy* of course. A judicial officer must answer for his *deputy* in civil actions, but not in criminal cases. Judges have no power to hold their courts by *deputy* except *de jure*, however, says do W. Co. Litt. 200. *deputatus*, because there is a judicial office of itself, annexed to their position. Sheriffs, however, of a county, bailiffs of a liberty, and constables, are allowed to appoint *deputies*.

DE QUIBUS for *de quibus*, in Law, a writ of entry. See *Writ* of Entry. Not. Rec. fol. 191.

DER, a syllable frequently prefixed to the names of places in England. It is said to signify that such were formerly places where wild beasts bred together, so called from the Saxon *deor*, first, which the situation was near some river.

DERBY *not*. See *DERBYSHIRE*.

DERDER, in the *Metamorphosis* of the *Geologists*, a name used by Aricæna and Sordapion, to express the common clay, whole bark they used on many occasions.

DERFELD, in our *Old History*, is used for a park, &c. a field of deer.

DEREGMENT, or **DERAIGNMENT**, in Law. The substantive *deraignment*, is sometimes used in the same sense with the French *deraignement* or *deraignement*, that is, to displace or set out of order. Thus we find *deraignement* or displacement out of religion, ana. 31 Hen. VIII. c. 6. and 5 and 6 Edw. VI. c. 13. Thus also we meet with *deraignment* or displacement of their practices, 35 Hen. VIII. cap. 20, which is said of those religious men, who disturb their order or positions. See *Kitchin*, fol. 432. The latter enters into religion, and afterwards in *deraignment*. And *Edw.* c. 21. *deraignment* doth stand for a punishment that may be challenged or defective, or not lawfully made. *Blanc.* de Veris. signific. verbo *deraignment*, makes it signify what we call waging and making of Law.

DERELICTS, from *derelictus*, and *relinquo*, *Relinquo*, in the Civil Law, are such goods as are usually thrown away, or relinquished by the owner.

DERELICT is also applied to such lands, as the sea receding from, leaves dry, and fit for cultivation.

If they are left by a gradual recession of the sea, they are assigned to belong to the owner of the adjoining lands; but when an island is formed in the sea, or a large quantity of new land appears, such *derelict* lands belong to the king.

DELLSIDE, in *Dulany*, a name by which some authors have called the tamarisk-tree. *Alph. Egypt.* p. 338.

DE REVOCATIONE *parlamentum*, the name of a writ for recalling a parliament. Thus in a Law. III. the parliament being summoned, was recalled by such a writ before it met. *Willelmus* Annal. on the 14th. l. 44.

DEREYN, or **DARATON**, *deroyante* vel *deroyante*, in our *Old Law*, is frequently used for the act of proving; that we find *deroyant* vel *deroyant* *parlamentum*. *Glave*, lib. 10. c. 6. And *deroyant* *parlamentum* in *verba mea*, lib. 10. c. 20. *Deroyant* after us in the same sense. *Edw.* *regium* *deroyant* *parlamentum* *deroyant*, lib. 10. c. 16. And so to make the act of *deroyant*, lib. 10. c. 22. And we find to *deroyant* the *deroyant*, in *Old Nat. Br.* fol. 146. To *deroyant* that right, 2 Edw. I. c. 4. and *Willelmus*, tom. II. c. 5. When the power of any church is disturbed, or demand takes in the territory by a writ of *deroyant*, the person that has a writ to demand the delivery of the bishop, being in demand, and when it is *deroyant*, then shall the plea be in the court Christian, as far forth as it is *deroyant* in the king's court.

DERIVATIO, in *Rhetorica* is a figure in which words that are derived from the same root come together in the same sentence. The figure is repeated in the following examples: *He would rather die a glorious death, than to live a sordid life.*

DERIVATION, from *der*, and *riens*, a *derivation* in Grammar, the affinity one word has with another, by having been originally formed from it.

DERIVATION, in Medicine, the act of diverting a humour which flows on one noble part, and drawing it to some other neighbouring part, where it is less dangerous.

Thus, in distensions upon the eyes, or teeth, they apply a blister behind the neck, to draw the matter thence; and in a quinsy, they practice bleeding in the *carotid*, or veins under the tongue, to divert the humour from falling on the throat.

DERIVATION. See *ANGLE*.

DERIVATIVE, in Grammar, a word which takes its origin from another word, called its primitive.

Such is the word *derivation* itself, which takes its origin from the primitive *riens*, a rivulet, or channel, out of which other streams are drawn; and thus *derivation*, *derivation*, &c. are derived from *riens*, *riens*, *riens*, &c.

DERIVATIVE or *derivation* in Law, are those which presuppose some other conveyance precedent, and only serve to enlarge, confirm, alter, reform, restore, or transfer the interest granted by such original conveyance. These are *recovery*, *confirmation*, *reversion*, *assize*, *assize*, and *assize*.

DERMA, in Medicine, the part, or skin of an animal; or the integument, investing the whole body, formed into the dermis, cortex, or cuticle.

The word comes from the Greek *derma*, is *deris*, or *cutis*.

The *derma* consists of two parts; the *organ* *dermis*, and the *organ* *dermis*. See *SKIN*.

DERMISTES, in Zoology, a genus of insects of the order of the *aphidina*, the antennae of which are of a clavated figure, and perforated transversely. There are several species of this genus, confounded by some with beetles, or *beetles*.

DERNIER *refert*. See *REASON*.

Whatever power is committed by the king to any other, the *dermier* *refert* is still remaining in himself; so that he may sit in court, and take cognizance of all causes except in treason, and other cases, where he himself is a party.

DEROGATION, from *derogare*, an act contrary to the preceding one, and that annuls, destroys, and revokes it, either in whole, or part.

Derogation, in general terms, are not regarded in justice; they must be in specific, and in formal terms. A new one imports a *derogation* of a former act; a second testament is a *derogation* of a first.

DEROGATORY, a clause importing *derogation*.

By the fifth law, if a person own himself self-interest in a certain feat, notwithstanding any instance he has obtained for the same, the act is *derogatory*.

DERVIS, or **DERVISH**, a name given to a sort of monks among the Turks, who lead a very austere life, and profess extreme poverty, though they are allowed to marry. The word is originally Persian, *درویش*, signifying a beggar, or person who has nothing, and because the religious, and particularly the followers of *Mirvans*, profess not to possess any thing, they call both the religious in general, and the *Mirvans* in particular, *Derwishi*, or *Derwishi*.

The *Derwishi*, called also *Mirvans*, are a Mohammedan order of religious; the chief, or *tankee*, however, was one *Mirvans*. They are now very numerous. Their chief monastery is that near *Cous* in *Namut*, where the general makes his residence, and where all the members of the order are held; the other houses are all dependent on this, by a privilege granted to this monastery under *Ottoman*.

The *Derwishi* affect a great deal of modesty, patience, humility, and charity. They always go barefooted, and open-breasted, and frequently burn themselves with hot irons, to insure themselves to patience. They always sit on Wedgwood, eating nothing on cloth till after sun set. *Derwishi* and *Yezidi* they hold meetings, at which the forefathers of the *Derwishi* preside. One of them plays all the while on a flute, and the rest dance, turning their bodies round and round with the greatest dexterity imaginable. Long custom to this exercise from their youth has brought them to such a habit, that if they do not amuse themselves in this practice, they fall sick with grief. *Derwishi*, in company of *Derwishi*, they perform the same of *Derwishi*, without any food or entertainment, but companion *Derwishi* playing all the while on the flute; after which he fell into an ecstasy, and therein received wonderful revelations for the

establishment of his order. They believe the flute an instrument conferred by Jacob, and the thymele of the Old Testament, because they sing the praises of God upon them. They profess poverty, chastity, and obedience, and really observe them while they remain *Deservies*; but if they choose to go out, and marry, they are always allowed.

The generality of *Deservies* are monks: but some apply themselves to agriculture, politer, &c. to amuse the people; others give into fortify and otage: but all of them, contrary to Mahomet's precept, are said to drink wine, brandy, and other strong liquors, to give them the degree of gaiety their order requires.

Besides their great *Deservies*, there are particular limits bestowed in some particular monasteries, as Nidrie, greatly revered in the mountains of Egypt, and held by some to be St. George; and by others, with more probability, the prophet Elias.

The *Deservies* are great travellers; and, under pretence of preaching, and propagating their faith, are continually passing from one place to another on which account they have been frequently cited as *foes*.

There are also *Deservies* in Persia, called in that country *Adas*, or *Adas of Osh*. They lead a very penurious, austere life, and preach the *Adas* in the forests, coffee-houses, and wherever they can meet with auditors. The Persian *Adas* are not little but taken to the people, and are in the utmost contempt among the men of *Adas*, and letters.

There are in Egypt two or three kinds of these that are in currency, and to a manner of the religious order, and live retired; though there are of these who travel and remain again in their country. Some take this character, and yet live with their families, and exercise their trades: of this kind are the *Deservies* at Damietta, who go once or twice a week to a little uninhabited convent, and perform their extraordinary exercises; these also seem to be a good people; but there is a third sort of them who travel about the country, and beg, or rather charge people to give, for whenever they find them from something must be given them. The people of these orders, in Egypt, wear an octagonal badge, of a growth white alabaster, at their girdles, and a high thin cap without any thing round it. Pecher's Egypt, p. 128.

DESART, or **DESERT**, a wild, uncultivated, uninhabited place or country as the *desert* of Libya, or the Thebaid, &c. Geographers use the word in the general for all countries little, or not at all, inhabited. In Scripture, we find several places in the Holy Land, or places adjoining thereto, called *deserts*. The *desert*, or wilderness, absolutely so called, is that part of Arabia on the south of the Holy Land, wherein the Israelites wandered, from the time of their evacuating Egypt to their entry into the Promised Land. The *desert* of Beethersa was that part of the *desert* just mentioned, which bordered on the Holy Land, running towards the Mediterranean. The *desert* of Idumea is Idumea itself, a barren, mountainous country. The *desert* of Bethazer, Beethaida, Cadeia, Damata, Dilion, Engaddi, Edom, Gebon, Harci, Jazer, Juth, Moab, Pharan, Sin, Ginnai, Zar, Zin, &c. are to many dry, uncultivated, and in general mountainous places, like our downs, &c. where there are few or no habitations or inhabitants; whence the Hebrews call them by improperly *deserts*, which properly signifies *human word*, or *speech*, because there is none heard there.

DESART, in *Costory*. See **DESERT**.

DESCANT, from *de*, and *cantus*, *sonus*, in *Musica*, originally signified an extemporaneous song, which was no sooner uttered than lost; but it was afterwards applied to the art of composing in several parts.

Descant is frequently, *viz.* plain, figurative, and double. **DESCANT**, Plain, is the ground-work or foundation of musical composition, and consists altogether in the orderly placing of many consonants, answering to simple counterpoint.

DESCANT, Figurative, or *figural*, is that wherein descants are concerned as well, though not so much, as in counterpoint. This may be well termed the ornamental or rhetorical part of music, because that in this are introduced all the varieties of points, figures, symphonies, diversities of measures, and whatsoever else is capable of adorning the composition.

DESCANT, Double, is when the parts are so contrived, that the whole may be made thus high; and, on the contrary, the bass the treble.

DESCENDANT, in *Genealogy*, a term relative to *ascendant*, and applied to a person who is born or issued from some other referred to. This, mankind are said to be *descendants* of Adam. The *descendants* from the brothers of the Maid of Orleans are confirmed in their exemption

from all taxes and imposts, by a regulation of the year 1634. See **DESCENT**.

DESCENDENS, *descensu*, in *music*, a name given by Fabricius, and others, to the muscle, called by Aëlius *abacus internus abdominalis*.

DESCENDING, something that falls, or moves, from above, downwards.

There are *ascending* and *descending* flats; and *ascending* and *descending* degrees.

There are also *ascending* and *descending* veins springing out of the *osasa*; and *ascending* and *descending* arteries rising out of the *osasa*.

DESCENDENT, in *Astronomy*, is the latitude of a planet in its return from the nodes to the equator.

DESCENSION, in *Astronomy*, is either *right* or *oblique*.

DESCENSION, *Right*, of a part of the sky, is a point, or arch, of the equator, which descends with the star, or sign, below the horizon, in a right sphere.

DESCENSION, *Oblique*, is a point, or arch, of the equator, which descends at the same time with a star, or sign, below the horizon, in an oblique sphere.

DESCENDING, both *right* and *oblique*, are accounted from the first point of *Aries*, or the vernal intersection, according to the order of the signs; that is, from west to east. And, as they are unequal, when it happens that they intersect to equal arches of the circle, as, in the circle, signs of the equator, it follows, that *descension* is greater part of the equator circle, or *descend*, within a sign, in which case the sign is said to *ascend*, or *ascend*, (quodlibet) and sometimes apply a like part of the equator rises, or sets, with the first sign, in which case it is said to *ascend* and *descend* obliquely. See **ASCENSION**.

DESCENSION, *Refraction* of light. See **REFRACTION**.

DESCENSIONAL, *difference*, is the difference between the right and oblique declination of the same star, or point of the heavens, &c.

DESCENT, in *Chemistry*. The separating mercury from its ore by *descent*, is performed in the following manner: take two earthen pots, with orifices of equal diameter; adapt an iron plate to the orifice of one of the two pots, in such a manner that it may rest upon the brink of it, but not sit so much all round; let this have several holes bored here and there in it, but not near the bottom; pour into this pure water, to about two inches high, then that it with the iron plate; put upon this plate a smaller vessel, containing the ore of mercury; then close these vessels, with the second pot inverted, stopping the joint with lute; bury the inferior pot in ashes, and put about the whole a moderate fire, continue it till the upper vessel is slightly red hot, and the mercury will be driven into the lower, in fumes, which will be condensed by the water into running quicksilver. Cramer's Art of Alchemy, p. 352.

DESCENT (in a *drain*, in *Architecture*, is a deep trench, or sap, cut through the virginity, and under the covering, covered above with planks and boards, and loaded with earth against artificial fire. See **DESCENT**.

In wet ditches the *descent* is made even to the surface of the water; in dry ditches, it is carried to the bottom of the moat, where travellers are made to lodge and secure the miners.

DESCENT, in *Genealogy* and *Heralry*, the order, or succession, of *descendants* in a line, or family.

We say, one *descent*, two *descents*, &c. A gentleman is of perfect blood who has four *descents* of gentility, both by his father's and mother's side, i.e. whole great grandfather, grandfather, and father, on both sides, were all gentlemen.

DESCENT is also used, in *Heralry*, to express the coming down of any thing from above.

Thus, a lion *in descent* is a lion with his head towards one of the side points, and his heels towards one of the corners of the shield, as if he were leaping from some high place.

DESCENT, or **DESCENT**, in *Law*, the order, or manner, wherein lands and revenues are derived to any man from his ancestors; and this is by custom, statute, or common law. By custom, as in *Common-law* or *Common-law* English, by statute, as in *STATUTE*, and by common law, when a person has lands of inheritance in fee-simple, and dies without disposing them, in which case the land descends in *descent* to the eldest son and heir.

Thus, to *make in descent* from his ancestors, is to show how, and by what particular degrees, the land in question came to a person from his ancestors. See **CONTINGENCY**.

Descent, in common law, is either *direct*, or *collateral*.

DESCENT, *Direct*, is that conveyed down, in a right line, from the grandfather to the father, and from the father to the son, from the son to the grandson, &c.

DESCENT,

DESCENT, Collateral, is that springing out of the side of the line, or blood; as from a man to his brother, nephew, or the like.

Judge Blackstone has collected and illustrated the following rules or canons of inheritance, according to which estates are transmitted from the ancestor to the heir.

"Inheritance shall lineally descend to the issue of the person last actually seized in fee simple; but shall never lineally ascend."

The affirmative part of this rule has been almost universally adopted by all nations: but the negative part, whereby parents and all lineal ancestors are excluded from succeeding to the inheritance of their offspring, is peculiar to our law; and those of the same original: for, by the Jewish law, on failure of issue the father succeeded to the son, in exclusion of brethren, unless one of them married the widow, and raised up seed to his brother. And, by the laws of Rome, the children or lineal descendants were first preferred; and, on failure of these, the father and mother or lineal ascendants succeeded together with the brethren and sisters; though by the law of the Twelve Tables, the mother was originally excluded, on account of her sex.

This rule was introduced into our law at the same time with, and in consequence of, feudal tenures; and though the right of succession in the ascending line was restored by Henry I. it was soon disused; for it was laid down as an established law in Glanville's time, under Henry II. *hereditas nunquam ascendit*; and this maxim has been invariable ever since. Another rule of inheritance is,

"that the male issue shall be admitted before the female."

This preference of males to females is entirely agreeable to the laws of succession among the Jews, and also among the states of Greece, or at least among the Athenians; but was totally unknown to the laws of Rome, now extant, which allow brethren and sisters to succeed to equal portions of the inheritance. It was derived to us from the feudal law, and admitted on the principle, that no female could succeed to a proper feud, because they were incapable of military service. However, according to our law, though daughters are excluded by sons, they succeed before any collateral relations. A third rule of descent is,

"that where there are two or more males in equal degree, the eldest only shall inherit; but the females all together." The Greeks, Romans, Britons, Saxons, and even originally the feudists, divided the lands equally; but when the emperors began to create honorary feuds, or titles of nobility, it was found necessary to make them impartible, or *feuda indivisa*, and descendible to the eldest son alone: in consequence of which, the eldest male began universally to succeed to the whole of the lands in all military tenures; and in this condition the feudal constitution was established in England by William the Conqueror. The fourth rule of descent is,

"that the lineal descendants, in fee simple, of any person deceased, shall represent their ancestor, or stand in the same place as the person himself would have done, had he been living." Thus the child, grand-child, or great-grand-child, male or female, of the eldest son succeeds before the younger son, and so in infinitum; and these representatives shall take neither more nor less, but just to much as their principals would have done. This is called a succession *in stirpes*, according to the roots; since all the branches inherit the same share that their root, whom they represent, would have done. The Jewish descent was directed in the same manner; but the Roman somewhat different. This rule was indisputably settled in the time of king Henry III. and has continued ever since. A fifth rule is, "that, on failure of lineal descendants, the issue of the person last seized, the inheritance shall descend to the blood of the first purchaser subject to the preceding rules." This rule was entirely unknown among the Jews, Greeks, and Romans; but the law of Normandy is the same with ours in this respect; both being derived from the same feudal origin. The sixth rule is, "that the collateral heir of the person last seized must be his next collateral kinsman of the whole blood." The last rule of descent is, "that in collateral inheritances the male blood shall be preferred to the female; that is, kindred derived from the blood of the male ancestors shall be admitted before those from the blood of the female; unless where the lands have, in fact, descended from a female." This is warranted by the examples of the Hebrew, Athenian, and Roman laws; and also of the customary law of Normandy. See farther on this subject Blackst. Com. vol. ii. chap. 14, post.

If one dies seized of land, wherein another has a right to enter, and it descends to his heirs, such descent shall take away the others right of entry, and put him to his action for recovery thereof. Stat. 31 Hen. VIII.

DESCENT, fall, in Mechanics, &c. is the motion, or tendency, of a body towards the centre of the earth, either directly or obliquely.

Vol. II. N° 94.

It is to be here observed, first, that a body cannot descend, unless it can divide and separate the medium; which it cannot do, unless it be specifically heavier than the medium. For since bodies cannot penetrate each other, one must give way before the other can move; and again, though a medium, e. gr. water, be divisible, yet, if it be specifically heavier than another, e. gr. wood, it is only heavier as it contains more particles of matter in the same bulk, all which have an impulse downwards; and, consequently, in water there is a greater impulse than in the same bulk of wood.

Secondly, The *defining* body loses as much of its weight, as is the weight of the medium, with the force of its cohesion.

And, therefore, a body specifically heavier *descends* in a fluid medium specifically lighter (e. gr. the air) with a force equal to the excess of the weight of the body above an equal bulk of the medium: for a body only *descends* in a medium with the force remaining, after a part has been spent in overcoming the resistance of the medium; and this resistance is equal to the weight of an equal bulk of the medium; consequently, the body only falls with the excess of its weight above that of an equal bulk of the medium.

Hence, the power that sustains a body in a specifically lighter medium, is equal to the excess of the absolute weight of the body above an equal bulk of the medium. Thus, 474 pounds of copper in water lose 54 of their weight. A power, therefore, of 42 pounds is able to sustain them.

Thirdly, If two bodies have the same specific gravity, the less the bulk of the *defining* body is, the more of its gravity does it lose, and the slower does it *descend*, in the same medium. For, though the proportion of the specific gravity of the body to that of the fluid be still the same in a greater or lesser bulk, yet the less the body, the more the surface, in proportion to the mass; and the more the surface, the more the friction of resistance.

Fourthly, If the specific gravities of two bodies are different, that which has the greatest specific gravity will *descend* with greater velocity in the air or other resisting medium than the other. Thus a ball of lead *descends* swifter than a feather, because it loses less of its weight, though in vacuum they both fall with equal velocity.

The cause of this *descent*, or tendency downwards, has been greatly controverted. There are two opposite hypotheses advanced: the one holding it to proceed from an internal, and the other from an external principle: the first maintained by the PERIPATETICS and EPICUREANS, and by the NEWTONIANS; and the latter by the CARTESIANS and GASSENDISTS. See also ACCELERATION.

Laws of the DESCENT of bodies. 1. Heavy bodies, in an unresisting medium, fall with an uniformly accelerated motion. See the *Laws of uniformly accelerated motion*, under the articles ACCELERATION and MOTION.

In supposing heavy bodies to *descend* in an unresisting medium, we conceive them free of all external impediments, from what cause soever. So that we even let aside that oblique impulse, given to bodies while in falling, by the rotation of the earth, though this produces no sensible irregularity in a little distance. Galileo, who first discovered the *law of the descent* of heavy bodies by reasoning, afterwards confirmed the same by experiments; the result of which, repeated often both by him and since his time, was, that the spaces of *descent* were as the squares of times.

Grimaldi and Riccioli made experiments to the same effect, though in a different manner, by letting fall a number of balls, weighing eight ounces apiece, from the tops of several towers, and measuring the times of falling by a pendulum. Riccioli, *Almag. Nov. tom. i. lib. ii. cap. 21. prop. 4.* These experiments are exhibited in the following table.

Since, then, the experiments of Riccioli, made in such considerable distances, agree so well with the theory, it is scarce worth taking notice of what is urged to the contrary by Dechales, in his *Mund. Math.* who writes, that he had found by experiment, that heavy bodies, in half a second of time, descend 4 feet; in two, 16; in three 36; in four, 64; in five, 100; in six, 144. It is sufficient that he devalues the irregularity from the resistance of the air, which we suppose out of the question.

2. If a heavy body descend, in an unresisting medium, through an interval not over-large, the space it describes, is the subsquare of that which it would describe, in the same time with the velocity acquired at the end of the fall.

3. The time wherein a body falls from a given height being given, to determine the spaces it fell in the several parts of that time.

Suppose the given altitude = a , the time = t , and the space it fell in one part of time x : then

$$\frac{1}{2} x : x :: t^2 : a$$

$$\frac{1}{2} x = \frac{t^2}{a}$$

$$x = \frac{2t^2}{a}$$

Therefore the space passed over in the first part of time is $\frac{a}{4}$; consequently, that passed over in the second time

= $\frac{3a}{4}$; that in the third = $\frac{5a}{4}$, &c. See ACCELERATION, art. 3.

Ex. gr. In the experiments of Riccioli, above delivered, the ball fell 240 feet in four seconds. Therefore the space fallen the first second was $240 \div 16 = 15$. The space in the second was $= 15 \times 3 = 45$. That in the third $= 15 \times 5 = 75$. And that in the fourth $15 \times 7 = 105$.

4. The time wherein a body falls through a given space being given, to determine the time wherein it will fall through any other given space, in the same medium. Since the spaces are as the squares of the times, to the space which the body falls in the given time, the space in the question, and the square of the given time, find a fourth proportional, which will be the square of the time sought. The square root, therefore, being extracted thence, the problem is solved.

For example; one of Riccioli's balls, in four minutes time, falling 240 feet, it is inquired in what time it would fall 432 feet? The answer will be found $= \sqrt{(135 \times 16 \div 240)} = \sqrt{(135 \div 15)} = \sqrt{9} = 3$.

5. The space a body falls in a given time being given; to determine the space through which it will fall in any other given time.

In the square of the time wherein the body falls through the given space, the square of the time wherein it should fall through the space required, and the given space, seek a fourth proportional; this will be the space required.

For instance, Riccioli's ball falling 240 feet in 4 seconds, it is asked what space it will fall through in 4 seconds? The answer is, $15 \times 60 \div 4 = 4 \times 60 = 240$. Wolf. Elem. Math. tom. ii. p. 14, &c.

For the *Law of the Descent of Bodies on inclined planes*, see INCLINED PLANE.

For the *Law of Descent in cycloids*, see CYCLOID, and PENDULUM.

DESCENT, *Line of swiftest*, is that which a body falling by the action of gravity, describes in the shortest time; which is proved by geometricians to be the cycloid.

DESCRIBE, is a term in *Geometry*, expressing some line or surface, which by its motion produces a plane figure, or a solid.

DESCRIPTION, in *Logic*, an imperfect, or inaccurate definition of a thing, giving a sort of knowledge thereof from some accidents and circumstances peculiar to it, which determine it enough to give an idea that may distinguish it from other things; but without explaining its nature or essence.

Grammarians content themselves with *descriptions*: philosophers require definitions of things. See DEFINITION.

A *description* is an enumeration of divers attributes of a thing, most of which are only accidental: as, when a person is described by his deeds, his sayings, his writings, his language, &c. A *description*, as to its outward appearance, resembles a *sketch*, and is even convertible with the thing described; but does not explain it. For, instead of bringing several things essential to the thing described, it only brings a number of accidents belonging thereto. Il. gr. Peter is the tall young man who lives on the green, wears black cloaths, frequents the college, courts N—, &c. where it is evident, we do not give any explication of Peter, as not bringing things that are in Peter, but only circumstances of things about him, his, young, living, wearing, frequenting, court-

ing, &c. A *description*, therefore, is no proper answer to the question, *quid sit*, what is he? but to that, *quis sit*, who is he?

Descriptions, in effect, are principally used for singulars, or individuals; for things of the same species do not differ in essence, but only as to *his*, and *his*, which difference contains nothing very notable, or distinguishable. But individuals of the same kind, differ much in accidents: e. gr. George is a king, and William a citizen; Charles is a male, and Anne a female; Henry is wife, and John a blockhead, &c. Thus, a *description* is an accumulation of accidents, whereby things are notably distinguished from each other, though they scarce differ at all in essence.

Some authors call a *description* a quasi-definition, as, body is a thing divisible, moveable, solid, extended, &c. which only falls short of a definition in this, that, instead of the form or essence of a thing, it gives one or more properties arising from the form or essence.

DESCRIPTION, in *Geometry*. To describe a circle, ellipsis, parabola, &c. is to construct, or form these figures, with rules, compasses, &c.

DESCRIPTION, in *Poetry and Rhetoric*, is a figure, which, by the aid of imagery and argument, exhibits such a strong and lively representation of a subject, as gives a distinct view and satisfactory notion of it to the reader or hearer; and whilst it convinces the mind, it moves and sways the passions. This figure is principally used by poets, not only with a design to move the passions, but to please the fancy. Historians also describe things, places and persons; and orators produce the greatest effect by *description*. The *description* of a person is called a character.

DESERTER, from *deser*. *I deserui*, in *War*, a soldier on the muster-roll, who quits the service without leave, or lifts himself under another officer, into a different regiment.

All soldiers found half a league from a garrison, or army, going towards an enemy's country, or quarter, without a pass, are deemed and treated as deserters.

A deserter is, by the articles of war, punishable by death, and after conviction is hanged at the head of the regiment he formerly belonged to, with his crime written on his breast; and is suffered to hang until the army leave the camp, for a terror to others.

For the manner of punishing deserters among the ancients, see TRANSUGA.

The ancient church excommunicated deserters, as having violated their oath.

By the ancient laws of this kingdom, desertion was deemed felony; but it is now punished by courts martial, under the annual acts against mutiny and desertion.

DESHABILLE, a French term, signifying of late. It properly signifies a night-gown, and other necessaries made use of in dressing or undressing. Mr. — is not to be spoken with, he is yet in his *deshabille*, i. e. undressed, or in his night-gown.

The word is compounded of the privative *de*, and *habiller*, in *deshabiller* itself.

DESHACHA, Br. from *de*, and *habere*, is not, in *Herakly*, is when a beast has its limbs separated from the body, so as they still remain on the cleavebone, with only a small separation from their natural places.

DESIDERATUM, from *desidero*, *I desire*, is used to signify desirable improvements in any art or science, as yet unattained. Thus, it is a desideratum with the blacksmith, to render iron fusible, by a gentle heat, and yet preserve it hard enough for ordinary uses; with the glass-maker and looking-glass-maker, to render glass malleable; with the clock-maker, to bring pendulums to be useful where there are irregular motions; with the brazier and cooper-smith, to make portable solder; with the shipwright, to build vessels that will fall under water; with the diver, to procure manageable instruments for conveying fresh air to the bottom of the sea sufficient for respiration, and the burning of lights; with the assayer, to melt by cold ores, or metals, immediately, without the use of bellows or furnace; and with the carver and joiner, to fashion wood in models like plaster of Paris, or burnt shalloon, &c. And though, as Mr. Boyle observes, the obtaining of this desideratum may be thought chimerical, yet it is proper they should be proposed; for although perfection may not be attainable, yet approaches to it may be made, and arts thereby improved. Vide Boyle's Works, vol. i. p. 129, 130.

In *flora*, all arts and sciences have their defects, and it is not at first to be pushed, for how many of these remedies may be found, by means of chemical and philosophical researches properly directed.

If a proper number of persons duly qualified for making experiments, and improving from them, would set about each his particular share of the necessary experiments, and communicate the result of all their processes to one another,

another, the business of chemical and philosophical experiments would be much better directed in regard to future students, and many of the *deftinatus* in the art probably supplied.

DESIGN, from *designo*, *to mark out*, the plan, or representation of the order, general distribution, and construction of a painting, poem, book, building, or the like.

The painter has drawn the first *design* of his piece, in which the figures are well disposed. The *design* of that poem, or book, is artfully laid. Claudian never sees his whole *design* together: when he composes a part, he thinks of nothing else, and works up every member, as if it were separate from all the rest.

In building we use the term **ISOMOGRAPHY**, when by *design* is only meant the plan of a building, or a flat figure drawn on paper. **ORTHOGRAHY**, when some face, or side, of the building, is raised from the ground. And **SCENOGRAPHY**, when both front and sides are seen in perspective.

DESIGN, in *Weaving Manufactures*, expresses the figures wherewith the workman enriches his stuff, or silk; and which he copies after some painter or draughtsman.

In undertaking such kinds of figured stuffs, it is necessary, that, before the first stroke of the shuttle, the whole *design* be represented on the threads of the warp; we do not mean in colours, but with an infinite number of little packthreads, which, being disposed so as to raise the threads of the warp, let the workman see, from time to time, what kind of silk is to be put into the eye of the shuttle, for weft.

This method of preparing the work, is called *reading the design*, or *reading the figure*, which is performed after the following manner. A paper is provided, considerably broader than the stuff, and of a length proportionate to that which is intended to be represented thereon. This they divide lengthwise, by as many black lines as there are intended to be threads in the warp; and cross these lines by others drawn breadthwise, which, with the former, make little equal squares. On the paper thus squared the painter *designs* his figures, and brightens them with colours, as he thinks fit. When the *design* is finished, a workman reads it, while another lays it on the simblet.

Now, to read the *design*, is to tell the person who manages the loom, the number of squares, or threads, comprised in the space he is reading; intimating, at the same time, whether it is ground or figure.

To put what is read on the simblet, is to fasten little strings to the several packthreads which are to raise the threads named. And thus they continue to do till the whole *design* is read.

Every piece being composed of several repetitions of the same *design*, when the whole *design* is drawn, the drawer, to be guided, as I may say, the *design* itself, has nothing to do, but to raise the little strings, with slipknots, to the top of the simblet, which he had let down to the bottom; and this he is to repeat as often as is necessary, till the whole be manufactured.

The ribbon-weavers have likewise a *design*, but much more simple than that now described: it is drawn on paper, with lines and squares, representing the threads of the warp, and weft. But in lieu of lines, whereof the figures of the former consist, these only consist of points or dots, placed in certain of the little squares formed by the intersection of the lines; these points mark the threads of the warp that are to be raised, and the spaces left blank denote the threads that are to keep their situation. The rest is managed as in the former.

DESIGN is particularly used, in *Painting*, for the first idea of a large work, drawn roughly, and in little, with intention to be executed, and finished in large. In this sense, the *design* is the simple contour, or outlines of the figures, or things intended to be represented, or the lines that terminate and circumscribe them.

Such a *design* is sometimes drawn in crayons, or ink, without any shadows at all: sometimes it is hatched, that is, the shadows are expressed by sensible lines, usually drawn across each other with the pen, crayon, or graver. Sometimes, again, the shadows are done with the crayon reddish, so that there do not appear any lines; sometimes the grain, or strokes of the crayon, appear, as not being rubbed; sometimes the *design* is washed, that is, the shadows are done with a pencil in Indian ink, or some other liquor; and sometimes the *design* is coloured; that is, colours are laid on much like those intended for the grand work.

The qualities, or conditions, required in a *design*, are correctness, good taste, elegance, character, diversity, expression, and perspective.

Correctness depends principally on the justness of the proportions, and a knowledge of anatomy. Taste is an idea or manner of designing, which arises either from

the complexion, and natural disposition, or from education, one's master, studies, &c. Elegance gives the figures a kind of delicacy which strikes people of judgment, and a certain agreeableness, which pleases every body. The character, is what is peculiar to each thing, in which there must be a diversity; in as much as every thing has its peculiar character to distinguish it. The expression, is the representation of an object according to its character, and the several circumstances it is supposed to be in. The perspective is the representation of the parts of a painting, or figure, according to the situation they are in, with respect to the point of sight.

The *design*, or draught, is a part of the greatest import and extent in painting: it is acquired chiefly by habit and application, rules being of less avail here than in any of the other branches of the art, as colouring, chiar-obscure, expression, &c.

The principal rules that regard the *design* are, that novices accustom themselves to copy good originals at first sight; not to use squares in drawing, for fear of flinching and confining their judgment; to lay till they can *design* well after the life, before they begin the practice of perspective rules; in *designing* after the life, to learn to adjust the bigness of their figures to the visual angle, and the distance of the eye from the model, or object; to mark out all the parts of the *design*, before they begin to shadow; to make their contours in great pieces, without taking notice of the little muscles, and other breaks; to make themselves masters of the rules of perspective; to observe every stroke, as to its perpendicular, parallel, and distance; and particularly so to compare, and oppose the parts that meet upon, and traverse the perpendicular, as to form a kind of square in the mind, which is the great, and almost the only rule of *designing* justly; to have a regard, not only to the model, but also to the part already designed, there being no such thing as *designing* with strict justice, but by comparing and proportioning every part to the first.

The rest relates to perspective; as, that those objects be seen at one view, whose rays meet in a point; that the eye and object be always conceived as immovable; that the space, or medium between them, be conceived transparent; and that the eye, object, and picture, be at a just distance, which is usually double the bigness of the subject, or picture. See **DESIGNING**, and **PERSPECTIVE**.

DESIGNATION, the art of marking or indicating, and making a thing known. The *designation* of such an estate is made by the tenants, buttments, and boundings. Among the Romans, there were *designations* of the consuls and other magistrates, some time before their election.

DESIGNATOR, a Roman officer who assigned and marked each person his place and rank in public ceremonies, shows, processions, &c.

The word is formed from the verb *designare*, to *design*. The *designator* was a kind of marshal, or master of the ceremonies, who regulated the feast, march, order, &c. There were *designators* at funeral solemnities, and at the games, theatres, and shows, who not only assigned every one his place, but also led him to it; as appears from the prologue to the *Poenulus* of Plautus. Much of the same nature were the *agnomatores* of the Greeks.

DESIGNING, the art of delineating or drawing the appearance of natural objects, by lines, on a plane.

To *design*, according to the rules of mathematics, makes the objects of perspective.

To *design* by the camera obscura, see **CAMERA obscura**.

Mechanical method of Designing by glass. Provide a square piece of glass, fixed into a frame, ABCD (Plat. Perspective, fig. 1.) and wash and smear it over with water, wherein a little gum has been dissolved. When it is well dried again, turn it towards the object or objects to be designed, so as that the whole thereof may be seen through a dioptra, or sight GH, fixed thereto: then proceed to work, and, applying the eye to the sight, with a pen and ink draw every thing on the glass, as you see it appear there: or the outlines of the objects may be drawn with black colour in drying oil. Having finished the draught, lay a fine melf paper thereon, and, pressing it pretty tight down, the whole will be transferred from the glass to the paper. This method is very good, easy, and exact, and deserves to be more used by painters. Some have used a piece of tiffany or fine lawn; and others, paper made transparent by means of oil of turpentine, instead of the glass: and the outlines of the objects are traced out by a crayon, formed of white or red chalk, charcoal, or any proper substance. If tiffany or lawn be used, they must be carefully laid on paper or vellum, and struck in every part with some flat body; by which means the matter of the crayon will

will be transferred from the old to the new ground; and the impression should be overtraced with a black lead pencil. The sketch on transparent paper may be transmitted to any ground, by puncturing it with holes near each other in the lines of the drawing, then fixing it on the ground, and dusting over it black lead, or any other coloured matter finely powdered, and tied up in a fine linen cloth. This dust will mark a sketch on the new ground, so that it may be over-traced by any kind of pencil or crayon.

The eye may be assisted in *describing* from nature by means of a plane divided into squares, which is formed by drawing cross lines, parallel to each other, on a tiffany or lawn framed, or on transparent paper or glass. This may be done with common writing ink, or in any other way that will render the lines visible; and the divided plane must be placed before the sight-board, as already directed. The ground, on which the sketch is to be taken, must be also formed into an equal number of squares; and the objects, thus seen through the squares of the transparent plane, will be easily disposed in their proper situation, and formed of a just magnitude, by placing them in the correspondent square of the ground: or, a frame may be prepared of a proper size, and the area of it divided into squares, by threads of a moderate thickness. A portable machine may be easily contrived for supporting the frame of the transparent plane, and the sight-board: this machine may be constructed by joining three legs together, in the manner of the surveyor's instruments, in a block; and fixing the frame, by means of a sliding foot, into the same box, that it may be raised higher or lower. The sight-board must have a foot likewise, by which it might be raised higher or lower; though this must not be fixed into the block, but into a sliding piece, which must pass through the block horizontally, so that the foot of the sight-board being fixed into it at right angles, the board may be brought nearer to, or drawn farther from, the transparent plane at pleasure.

The following apparatus was used by Sir Christopher Wren for the purpose of *describing*. A is a small light with a short arm B (see *Tab. Perspective, fig. 2.*) which may be turned round about, and moved up and down on the small cylinder CD, which is screwed into ED at D: this piece ED moving round about the centre E, by which means the light may be removed either towards E or F. EF is a ruler fastened on the two rulers GG, which rulers serve both to keep the square frame SSS perpendicular, and, by sliding through the square holes TT, to slide the light, either nearer to or farther from the said frame: on which frame is stuck on with a little wax the paper OOOO, on which the picture is to be drawn by the pen I. This pen I is to be fixed, by a small brass handle V, to the ruler HH, that the point I may be kept very firm, so as always to touch the paper. HH is a ruler, that is always moved horizontally, or parallel to itself, by means of the small strings *aaa*, *bbb*; at the end of this ruler, is stuck a small pin, whose head P is the light, which is to be moved up and down on the outlines of any object. The two strings *aaa*, *bbb*, are exactly of an equal length. Two ends of them are fastened into a small leaden weight, which is moved in a socket on the back side of the frame, and serves exactly to counterpoise the ruler HH: the other two ends are fastened to two small pins HH, after they have ruled about the small pulleys MM, LL, KK by means of which pulleys, if the pen I be taken hold of and moved up and down the paper, the strings moving very easily, the ruler will always remain in an horizontal position. When the instrument is used, it is set upon a table, and the light A is fixed at any height above the table, and at any distance from the frame SSSS, at pleasure. Then the designer, looking through the light A, and holding the pen I in his hand, moves the head of the pin P up and down, over the outlines of the object, and the point I will describe on the paper OOOO, the shape of the object to trace.

DESIGN, in *Etymology*, the Macedonian name of the Athenian Month. **ANATHESIS**.

DE SON TORT *Simplex*, in our Law, words of form, used in an action of trespass by way of reply to the defendant's plea. Thus, if A. sues B. in such an action; B. answers for himself, that he did that which it calls a trespass by the command of C. his master. A. replies that B. did it *de son tort simplex*, *par ce que C. luy commande n'est de formes*; that is, B. did it of his own wrong, without C.'s commanding him in such manner and form.

DESPOIL, a title or quality given to the princes of Wallachia, Serbia, and some of the neighbouring countries. The word, in its full origin, signified the same with the Latin *heres*, and the English *heir*; but, in time, it underwent the same fate on *ordals*, as, among the Latins,

Cæsar did with regard to Augustus; **BACIAETC** answering to Augustus, and **ΔΕΙΟΤΗC**, *despoil*, to Cæsar.

Thus Nicephorus, having ordered his son Stauracius to be crowned, the son, out of respect, would only take the name **ΔΕΙΟΤΗC**, leaving to his father that of **BACIAETC**. For it is to be noted, that it was just about the time that the emperors began to cease to use Latin inscriptions.

This delicacy, however, did not last long; for the following emperors preferred the quality of **ΔΕΙΟΤΗC**, to that of **BACIAETC**, particularly Constantine, Michael Ducas, Nicephorus Botonites, Romanus Diogenes, the Comneni, and some others.

In imitation of the princes, the princesses likewise assumed the title of **ΔΕΙΟΙΝΑ**.

It was the emperor Alexius, furnished the Angel, that created the dignity of *despoil*, and made it the first after that of emperor, above that of Augustus, or Sebastocrator, and Cæsar. See **ANGEL**.

The *despoils* were usually the emperor's sons, or sons in law, and their colleagues, and copartners in the empire, as well as their presumptive heirs. The *despoils*, that were sons of the emperors, had more privileges and authority than those that were only sons in law. Codin. p. 38. describes the habits and ornaments of the *despoil*. See the notes of father Goar on that author.

Under the successors of Constantine the Great, the title *despoil of Sparta* was given to the emperor's son, or brother, who had the city of Sparta, or Lacedæmon, by way of appanage.

DESPOΤΙSM, or **DESPOTIC government**, a form of government wherein the prince is absolute and arbitrary, doing whatever he lists, without being checked by any other power. Such are most of the eastern governments, as those of the mogul, grand signior, sultan of Persia, &c.

DESPOUILLE, *Fr.* in *Herbals*, is the whole case, skin, or flough of a beast, with the head, feet, tail, and all appendances, so that being filled, or stuffed, it looks like the entire creature.

DESPUMATION, of *de*, priv. and *spuma*, froth, the clarification of any liquor, by throwing up its foulness in a froth, and taking that off.

DESQUAMATION, from *de* and *squama*, I scule, expresses the flaking or scaling of carious bones. See **EXFOLIATION**.

DESSERT, or **DESSERT**, *Fr.* the last service brought on the tables of people of quality, when the meats are all taken off. The *dessert* consists of fruits, pastry-works, confections, &c.

DESSICATIVE, or **DESECCATIVE**, from *desiccare*, I dry up, in *Medicine*, a remedy that has the virtue of drying up superfluous moisture, used to skin over old sores, &c. We say a *desiccative* unguent, &c.

Pimpinella is held deturpative, *desiccative*, and volucary. *Leucery*.

DESTILLATION, or **DISTILLATION**, in *Chemistry*. See **DISTILLATION**.

DESTINIES, in *Metaphys.* See **PARCA**.

DESTINY, from *desino*, I order, the order, disposition, or chain of second causes appointed by Providence; and importing or carrying with it, a necessity of event.

According to many of the heathen philosophers, *destiny* was a secret and invisible power, or virtue, which, with incomprehensible wisdom, conducted what it so appears irregular and fortuitous. This amounts to what we call God.

The Stoics, by *destiny*, understood a certain constentation of things, which, from all eternity, follow each other of absolute necessity, there being no power able to interrupt their connexion. This answers, in a great degree, to our idea of Providence.

But the Stoics made even the gods themselves subject to the necessity of the *destiny*. The truth is, the Stoics rather define what the word *destiny* should signify, than what it did signify in common language: for they had no sufficient idea of this power, to which they attributed those events. They had only a vague, confused idea of I know not what chimera, or unknown cause, to which they referred that inevitable disposition, and the eternal constentation of all things. There is no real being that the name *destiny* can express to. The heathen philosophers, who had framed a notion thereof, supposed it to exist, without knowing precisely what they meant by it. But men, not daring on the one side to impute to Providence the evils and misfortunes that befall them, as they imagined, undeterredly; and, on the other side, not being willing to allow that it was their own fault, formed this phantom of *destiny*, to bear the weight of all the evil.

DESTRUCTION, passively taken, is the corruption or anni-

annihilation of something before existing. See CORRUPTION.

A thing passes from *esse* to *non esse*, either by corruption, when nothing of the substance is left, but only the accidents, viz. the disposition of parts; or, by annihilation, when both substance and accidents are lost.

DESUDATION, from *desudo*, *I sweat much*, expresses a profuse and inordinate sweating, followed by the eruption of *sydamina*, or heat-pimples.

DESULTOR, from *desulo*, *I vault*, in *Antiquity*, a vaultier, or leaper, who jumped off one horse upon another.

Among the Scythians, Indians, and Numidians, the cavaliers, or horsemen, who served in the wars, were very expert *desultores*; that is, they always carried with them at least two horses, and when that they were mounted on grew weary, or wanted breath, they leaped, with great agility and address, upon the other which they led in their hand.

The Greeks and Romans borrowed the same practice from those barbarous nations; but they only used it in their games, races, and funeral solemnities; and never, that we read of, in war. The *desultores*, therefore, were, among the people of Asia and Africa, soldiers; but, among the Romans, Sec. they were no more than tumblers and posture-masters. Eustathius, on *Homer's Iliad*, lib. iv. assures us, that, instead of two, they had sometimes four or six horses, all a-breast, and would jump from the first to the fourth, or sixth, which was the master-piece of their art.

DETACHED Piece, in *Fortification*, are demi-lunes, ravelins, horns and crown-works, and even bastions, when separated, or at a distance from the body of the place.

In *Painting*, the figures are said to be well detached, or loosened, when they stand free, and disengaged from each other, are no where confounded together, but stand out with a strong relief from the ground, and from each other.

DETACHMENT, from the French *détacher*, *to part from*, a military term, signifying a certain number of soldiers, taken out of several regiments or companies equally, to be employed in some particular enterprise; as, to form a kind of flying camp, to relieve a party already engaged in battle, to join a separate army, to assist at the siege of a place, or to enter into some parishion. The number depends on the dignity of the officer in command; thus, two thousand or three thousand men form a detachment for a general officer, eight hundred for a colonel, five hundred for a lieutenant-colonel, two or three hundred for a major, eighty or a hundred for a captain, forty for a lieutenant or ensign, twelve for a serjeant, and fix for a corporal.

DETACHMENT of a fleet or squadron, a certain number of ships chosen by an admiral or commodore from the rest of the fleet, and charged to execute some particular service.

DETAINER, in *Law*. See *FORCIBLE entry*.

DETENTION, from *detineo*, *I detain*, the possession, or holding, of lands, or the like, from some other claimant.

The word is chiefly used in an ill sense, for an unjust withholding, &c.

The canon condemns a person who has intruded into a benefice, to make restitution of all the fruits thereof, during the time of his unjust detention.

DETENTS, in a clock, are those stops, which by being lifted up or let fall down, lock and unlock the clock in striking.

DETENT-wheel, or *Hoop-wheel*, in a clock, that wheel which has a hoop almost round it, wherein there is a vacancy, at which the clock works.

DETERGENT, from *detergo*, *I cleanse*, in *Medicine*, is applied to remedies that cleanse, and carry off viscid and glutinous humours.

The plant buckthorn deterges, and consolidates wounds. Rhaponticum is aperitive, and good against the gravel and stone; it also deterges, and expels poison.

Detergents are not only softening and adhesive, but also, by a peculiar activity, or disposition to motion, joined with a suitable configuration of parts, are apt to abrade, and carry along with them, such particles as they lay hold of in their passage. All medicines of this intention are supposed to cleanse and heal, that is, incarnate, or fill up with new flesh, all ulcerations and foulness occasioned thereby, whether internal or external. To do this, in all internal cases especially, the medicine must be supposed to maintain its primary properties, until it arrives at the place of action; and there it does what entitles it to the appellation of a *detergent*, and a *vulnery*; first, by its adhesive quality, which consists in the comparative largeness of surface, and flexibility of its component parts, by which it readily falls into contact with, and adheres to, the slough of ulcerous exudations,

which, by their loose situations, are easily carried along with the medicine; and when such matter is to be carried away, which is the cleansing and deterring part, what was instrumental in this office, will afterwards stick and adhere to the cutaneous filaments, until, by their addition, and the protrusion of proper nourishment, *ab interno*, to the same place, the waste is made up, that is, the ulcer is healed. Quinoy.

After the like manner is the operation of *detergents* to be accounted for in external application. By the warmth of their parts they rarefy, and by their adhesive quality they join with, and take off along with them, in every dressing, what is thrown upon the place to which they are applied, until a more convenient matter is brought thither by the circulating juices, which they assist in adhering to, and incarnating the eroded cavities. Only this may be taken notice of, that internally, whatsoever of this kind is mixed with the animal fluids, by the known laws of circulation, will be first separated, and left behind; for all those parts which are specifically heavier, will move nearest the axis of the canals, because their moments are the greatest, and will carry them, as near as can be, in straight lines; but the lighter parts will always be driven to the sides, where they soon meet with outlets to get quite off, or are struck into such cavities as we are here speaking of, in which they adhere, and make part of the substance.

This is understood of the milder sort of *detergents*; and it is easy to conceive from hence, how an increase of those qualities of activity and adhesion conjointly, may make a medicine arise to the greatest efficacy in this respect. And it is upon this foot that all these medicines operate which are given to cleanse obstructions, or foulnesses, in any of the *viscera*, or passages; and which may be increased in efficacy so far, as to fetch off even the membranes, and part of the capillary vessels.

Many *detergents* are of the genus of *balanics*; and some only differ in their degree of subtilty and efficacy, from what are called *vulneraries*.

The principal simples in this class are the leaves of wormwood, garlic, leeks, cyprip, scurvygrass, fumitory, liverwort, tansy, and vervain; bitter almonds, figs, julebs, raisins, dates, juniper-berries; gum ammoniac, balsam of Capivi, balm of Gilead, tucamahaca; turpentine; barberries, liquorice, turmeric, madder, spermaceti, mummy, sulphur, salt, mercury, and native cinabar. These the reader will find particularly described under their proper articles.

The pectoral *detergents* are the best of all medicines in the decline of an hæmorrhage by the mouth, in which blood has been voided clear from the lungs; in this case they never fail to resolve any grumes that may remain in the part; and at the same time, wonderfully restore the due tone of the *viscera*. The most proper on this occasion are decoctions of daily-leaves, ground-ivy, speedwell, and the small nettle, with powders of nitre, and dried goat's blood, and a mixture of an ounce of crab's eyes in a pint of white wine.

They are given in consumptions in many cases, and the most proper on this occasion are the saline ones, with the common absorbents, saturated with acids.

DETERIORATION, an act whereby a thing is impaired or rendered worse.

When the *deterioration* of a commodity, seized by an officer, arises from the fault of the keeper, he is answerable for the same.

J. Kedicke Mayer, professor at Leipzig, printed a treatise of *deterioration*, in the year 1695, under the title of *Tractatus de Deterioratione*.

DETERMINE, from *detinere*, *I detain*.

DETERMINE, in *Mathematics*, is that which has but one, or at least but a certain number of solutions, in contradiction to an indeterminate problem, which admits of infinite solutions.

Such, e. gr. is the problem, To describe an isosceles triangle on a given line, whose angles at the base shall be double that at the vertex; which has only one solution; as that which follows has two, viz. To find an isosceles triangle, whose area and perimeter are given.

A *determine* problem may either be simple or linear, plane, solid, or surfolid.

DETERMINATION, in *Physics*, the disposition or tendency of a body towards one way, rather than another.

Heavy bodies have a *determination* towards the centre of the earth.

DETERMINATION is also used for the action whereby a cause or agent is limited, or restrained, to act, or not act, in this or in that manner.

Determinations, say the schoolmen, proceed either from an efficient cause; in which case the *determination* is called effective; as, when an artist determines an instrument to a certain action; or from the form, at that determines

termines the indifference of the matter; and thus our senses are said to be *determinations* to have ideas upon the presence of external objects.

Or the *determination* is from the matter or subject that receives the action; and thus the heating of fire upon clay *determines* it to harden, upon wax to *soften*, &c. Or it is from the object; as when we say, colour *determines* the visual power; or, hilly, it is from the end, as the end *determines* the desire.

Determinations, again, are either moral or physical. A moral *determination* is that proceeding from a cause which operates morally, i. e. by commanding, persuading, or advising, some effect. This is the only kind of influence or *determination*, which is consistent with man's free moral agency; or indeed with any agency at all.

Physical *determination* is an act whereby God excites and applies a second cause to act, antecedently to all operation of the creature. Such a *determination* the Thomists and Dominicans maintain necessary to all the actions of every creature. The Jesuits, on the contrary, say that God *determines* even second causes, and hold, that God exerts no influence on second causes, but only with the second cause on the action. And thus they exclude a physical *determination*, both from natural causes, as supposing them already determined by nature to act; so that there needs no other external *determination* from God to the several actions; and from free causes, as supposing such a predetermination contrary to our natural liberty.

A *determination* to be pleased with certain forms, or ideas, an ingenious author calls an *internal fate*; and a *determination* to be pleased with virtuous actions, characters, manners, &c. a *moral sense*.

DETERMINATIVE PROPOSITION, in Logic. See COMPLEX PROPOSITION.

DETERTRATION, from *de*, and *terra*, is used to signify a removal of the earth, sand, &c. from the mountains and higher grounds, down into the valleys and lower parts. This is occasioned by rains, which wash the earthy matter down by degrees; but this cannot be very considerable, or much raise the surface of the earth, as some have imagined, because a good part of it is sunk into the clefts and caverns of the rocks and mountains, a great quantity is borne down into rivers, and thence into the sea, and the rather and finer part help to compose the bodies of plants and vegetable.

DETERGIVES, in Medicine, the same with DETERGENT. A cyther is a *deterrive* medicine, which cleanses the lower venter. *Deterrive* unguents are also called *manifacations*. The leaves and fannets of the flusberry are *deterrive* and abstrigent.

DETERSOR, from *de*, and *terro*, in Antiquity, a servant whose business it was to attend at dinner, and wipe the table. Plin.

DETERSORIUM, in Antiquity, a name given to the common wash, which was bean-meal, called *immonitio*, or the meal of a sort of pulse called *lupini*: this last they called *terro*.

The ancients, when they bathed, used various washes for cleansing the skin; but *natum*, and this thin fluid, called in Greek *epistemon*, were most common.

DETINUE, a writ which lies against a man who, having goods, or chattels, delivered to keep, refuses to redeliver them.

Detinue imports, in great measure, to the *actio legis* of the civilians. He takes his *actio* of *detinue*, to recover the thing *detained*; not the damages sustained by the *detinue*. For this reason this action is seldom brought; actions of trover and conversion being used instead of actions of *detinue*.

DETINUE of charters. A man may have *detinue* for deeds and charters concerning land; but if they concern the freedom, it must be in C. B. and no other court. Action of *detinue* lies for charters which make the title of lands; and the heir may have *detinue* of charters, although he hath not the land. If my father be defrauded, and die, I shall have *detinue* for the charters, notwithstanding I have not the land; but the executor shall not have *detinue* for them. New Nat. Br. 308.

DETINUE of goods in *quasi* marriage, is on a divorce between a man and his wife, after which the wife shall have this writ of *detinue* for the goods given with her in marriage. Mich. 35 Elix. 1. New Nat. Br. 308.

DETONATION, in Chemistry, the noise which some minerals, and other bodies, make, when they begin to burst in cracks by the volatile parts rushing out with impetuosity, and the humidity escaping.

The word is formed of *de*, and *tono*, I thunder.

Detonatio is more the same with *deturpation*; only its action is more forcible, and the noise is greater. Such as the explosion of gunpowder, fulminating gold, and fulminating powder; but as nitre is the cause of most explosions, the word *detonatio* has been appropriated to

the inflammation of the acid of this salt with bodies containing phlogiston; and it is frequently given to those inflammations of nitrous acid with sulphur, gold, and metals, which are not accompanied with explosion.

Detonatio takes away the impure volatile phlogiston from bodies.

DETONATION denotes the act, or operation, of expelling the impure, volatile, and sulphurous part, out of antimony, and leaving behind the fixed and internal parts. This is chiefly performed by means of sulphure, &c. See ANTIMONY.

DETONATION of nitre, consists in the instantaneous inflammation and decomposition of the acid of nitre, when it immediately touches combustible bodies, the phlogiston of which is ignited, or when the acid is ignited. This is effected by applying the nitre to a red-hot combustible body, or by making the acid itself red-hot, and applying a combustible body to it, in that state. During the *detonatio*, a considerable fume arises, containing no acid. See CAUSAS OF NITRE. What remains in the crucible, after the nitre and acid is thus burnt, is the fixed alkali, which was the basis of the nitre. Mr. Macquer conjectures that the *detonatio* of nitre cannot take place, unless a combination be previously formed between its acid and the phlogiston of the combustible substance used in the operation; that this combination is entirely similar to that of vitriolic acid with phlogiston, when sulphur is formed; and that, in the present instance, a nitrous sulphur is formed, infinitely more combustible than the vitriolic sulphur, and even to combustibility, that it cannot exist an instant without being entirely burnt; and on this account, it is inflamed with extreme rapidity and violence as soon as it is formed. He also gives a number of facts to establish this conjecture, from which he also infers, that nitrous acid, which is expelled from any body, is incapable of *detonation*; and that the strength or weakness of the *detonatio* depends on the greater or less addition of the nitrous acid with its basis. He observes that there is a very considerable difference in the phenomena of their combination, between the vitriolic and nitrous sulphur; the former burns very weakly; produces a flame which is very little luminous; requires for the continuance of its burning a constant supply of new air; and its acid undergoes no change by this combination. Nitrous sulphur, on the contrary, appears capable of existing an instant without burning; its vivid, dazzling flame, accompanied with noise, resembles the flame of a fire strongly actuated by a blast of air; it needs not the contact of external air; it burns with the same violence and rapidity in close vessels; no obstacle is capable of containing it; and if it be confined, it bursts with a terrible noise the sides of the containing vessels; and after its combustion no trace is to be found of its acid.

In order to account for this difference, he adopts the opinion of Stahl, who considers the nitrous acid as composed of a watery and an earthy principle, as well as all other acids; and besides these, of a third principle, which is phlogiston, in such a quantity as to assume all the properties, and particularly the immutability, essential to its nature. Thus he accounts for the *detonation* or total decomposition of the acid in nitrous sulphur when it is inflamed. The explosion accompanying the *detonation* of nitre proceeds from a great and sudden dilatation of some very extensible body: this body Stahl and Macquer suppose to be the water of the phlogiston rather of its acid; which acquires in the operation the properties of air. But others, with greater reason, maintain, that this elastic fluid is not the water of the nitre rarefied and converted into air; because the water of the nitre is only rarefied by the heat of the *detonation*, and is afterwards condensed by cold, forming the water called CRYSTALLINE OF NITRE. Besides, the elastic fluid thus produced is permanent, and not condensable into a liquid. Mr. Robins found, by accurate experiments, that the fluid produced by firing gunpowder, when confined within a space equal to that of the gunpowder which was fired and reduced to the heat of the atmosphere, was capable of sustaining a pressure equal to 244 times the pressure of the atmosphere; and that the elastic force of the fluid was increased probably about four times by the heat produced by the firing of the powder; and consequently, that it is thereby rendered capable, at the instant of explosion, of sustaining a pressure nearly equal to a thousand times the pressure of the atmosphere here. Dr. Priestley confirms the opinion advanced by Stahl, and adopted by Macquer and other chemists, that the nitrous acid is destroyed and strictly decomposed, in the process of *detonation*; he supplies, that, though the common properties of the acid, as combined with water, disappear, it is only in consequence of its combination with some earthy or inflammable matter, with which it forms some of the many species of air, into the composition of which this wonderful acid enters. Dict. of Chemistry. Robins's

New Principles of Gunnery, prop. 4. and 6, in his Tracts, vol. i. p. 63-72. Puclet's Exper. &c. on Air, vol. ii. p. 61.

DETRAHENS *quadratus*, in *Antiquis*, a name given by some authors, particularly Spigellus, to a muscle, called by the generality of anatomists the *platina mydei*; and, by Albius, *latissimus cili*. Douglas calls it also *quadratus* *generis*.

DETRANCHE, among the French *Heralds*, signifies a line bendwise, which does not come from the very dexter angle, but either from some part of the upper edge, and thence falling thence, or diagonally, or from part of the dexter side. They say, *tranche, déranche*, and *retranche*; to denote, that there are two diagonal lines, making two partitions in the escutcheon, and coming from the angles, and a third from some of the other parts above mentioned. See *Traverse*.

DESTAVIE, or *Deavavander hant* *spahuis*, is a writ that lies against executors or administrators, for paying debts upon simple contract and legacies, before debts on bonds and specialties, &c. for in this case they are as liable to actions, as if they had squandered away the goods of the deceased, or converted them to their own use; and are compellable to pay such debts by specialty out of their own goods, to the value of what they so paid illegally. Dyer, 232. But if an executor pays debts upon simple contract, before he hath any notice of bonds, it is no *deavavand*; and regularly this notice is by an action commenced against him; for the law doth not oblige him to take notice of it himself, nor of a judgment against his testator; because he is not privy to acts done either by or against him. 1 Mod. 175. 3 Lev. 115.

DEUCALION, in *Mythology*, was the son of Prometheus who married Pyrrha, the daughter of Epimetheus. Some have supposed that *Deucalion*, whom the Greeks have represented under a variety of characters, and concerning whom their poets have given many fabulous accounts, was the same with the patriarch Noah; and that *Deucalion's* flood in Thessaly, as well as that of Ogyges in Africa, and of Prometheus in Egypt, were the same with that of Noah, recorded in Scripture. Diodorus Siculus expressly says, that in the deluge which happened in the time of *Deucalion*, almost all flesh died. Apollodorus having mentioned *Deucalion* *re-natus*, confined in an ark, takes notice upon his quitting it, of his offering up an immediate sacrifice, *As peris, to the gods who delivered him*. As he was the father of all mankind, the ancients have given him great dignity and universal monarchy; though sometimes he is reduced to a petty king of the *Thessaly*. Apollonius Rhodius makes him a native of Greece, and the son of Prometheus. We may learn, however, from their confused history, that the person represented was the first of men, through whom religious rites were renewed, cities built, and civil polity established in the world: none of which circumstances are applicable to any king of Greece. Philo assures us, that the Grecians call the person *Deucalion*, but the Chaldeans style him *Noe*, in whose time there happened the great eruption of waters. But as Lucian has given us the most particular history of the deluge, and that which comes nearest to the account given by Moses; and as he was a native of Samosata, a city of Commagene upon the Euphrates, a part of the world where memories of the deluge were particularly preserved, and where an obvious reference to that history may be observed in the rites and worship of the country, we shall terminate this article with an extract of what he says on the subject.

Having delivered Noah under the name of *Deucalion*, he says, that the present race of mankind are descended from those who first existed, for those of the antediluvian world were all destroyed. The present world is peopled from the sons of *Deucalion*; having increased to great a number from one person. In respect to the former brood, they were men of violence, and lawless in their dealings. They regarded not oaths, nor observed the rites of hospitality, nor showed mercy to those who sued for it. On this account they were doomed to destruction; and for this purpose there was a mighty eruption of waters from the earth, attended with heavy showers from above; so that the rivers swelled, and the sea overflowed, till the whole earth was covered with a flood, and all flesh drowned. *Deucalion* alone was preserved to re-peopled the world. This mercy was shown to him on account of his justice and piety. His preservation was effected in this manner: he put all his family, both his sons and their wives, into a vault which he had provided, and he went into it himself. At the same time animals of every species, birds, horses, lions, ferrets, whatever lived upon the face of the earth, followed him by pairs; all which he received into the ark, and experienced no evil from them; for there pre-

valled a wonderful harmony throughout by the immediate influence of the Deity. Thus were they waited with him, as long as the flood endured.

After this he proceeds to mention that, upon the disappearing of the waters, *Deucalion* went forth from the ark, and raised an altar to God. Diocl. Sic. lib. i. p. 40. Apollod. lib. i. p. 20. Apollon. Rhod. lib. iii. v. 1685. Philo Jud. de Praemio & Poena, vol. ii. p. 412. Lucian de Dea Syria, vol. ii. p. 182.

Dr. Bryant produces a variety of monuments, that bear an obvious reference to the deluge, in the gentile history, besides this account of *Deucalion* and his flood. Analysis of Ancient Mythology, vol. II. p. 293-295.

DEVENERUNT, a writ anciently directed to the executor, on the death of the heir of a tenant of the king holding in capite, within age, and in the king's custody; commanding the executor to enquire, upon the oath of good and lawful men, what lands and tenements, by the death of the tenant, come to the king. This writ is now disused.

DEVEST, *Devestire*, in *Fœdal Writers*, is used for the opposite to investing. *Investire* signifies *possessionem suam tradere*. On the contrary, *devestire* is *possessionem auferre*. Fœd. lib. i. c. 7. Corol.

DEVIATION, in the *Old Astronomy*, a motion of the deferent, or eccentric, whereby it advances in, or recedes from, the ecliptic. See *DIFFERENCE*.

The greatest *deviation* of a planet is equal to the inclination of its orbit to the plane of the ecliptic. See *INCLINATION of a planet*.

DEVISE, in *Painting*. See *DEVIS*.

DEVIL, *Diabolus*, an evil angel; one of those celestial spirits cast down from heaven, for pretending to equal himself with God.

The word is formed from the French *diabol*, of the Latin *diabolus*, which comes from the Greek *diabolos*, *anagor*, or *convincator*; or from the ancient British *deifol*. The Ethiopians paint the devil white, to be even with the Europeans, who paint him black. Ludolph.

We find no mention of the word devil in the Old Testament; but only of Satan: nor do we meet with the word devil, in any heathen authors, in the signification attached to it among Christians; that is, as a creature revolted from God: their theology went no farther than to evil geni, or demons, who harassed and persecuted mankind. That the Chaldeans believed both a good principle, and an evil principle, which was an enemy of mankind. See *DAEMON*, and *DEMOMON*.

The religion we have of the religion of the antediluvians, as well as of some idolatrous nations, who worship the devil, but the term devil must not be here taken in the common sense; those people have an idea of two collateral independent beings; one whereof is good, and the other evil. And they place the earth under the guidance and direction of that evil being, which our authors, with some impropriety, call the devil.

DEVIL, See *Diabolus moribus*, in *Leibniz*, the name of an ugly and strangely ill shaped fish, or the ray kind. Its nose or snout is bifid, and runs out into two horns; and its sides are both terminated by thin fins: its skin toward the head is variegated with dusky spots. It grows to a very considerable size, being sometimes caught of six or seven feet length. Ray's Ichthyog. Append. p. 5. See *Tak. of Fish*, N. 6.

DEVIL in a bush, *Nigella*, in *Poetry*. See *FENNEL-flower*.

DEVIL's bit. See *SCABIOUS*.

DEVIL's bit, *Yellow*, *Leontodon*. See *DANDELION*.

DEVINCTION, *Devinctio*, in *Antiquity*, was used to signify a love-charm or incantation to gain the affection of a person beloved.

It was done by tying knots, and differed little from what was called *magia*, or *catagynous*. Virgil, in his eighth Eclogue, describes it thus:

*Nalla tribus vultu terens, Amyclis, artem
Nolle, Amphiloch, mola 12 Pœnias, dæ, vincula nalla.*

DEVISE, or *DEVIS*, in *Heraldry*, a name common to all figures, ciphers, characters, rebuses, mottoes, &c. which by their allusion to the names of persons, or families, denote their qualities, nobility, or the like. *Devise*, in this sense, is of a much older standing than heraldry itself, being that which gave the first rise to armigerous. Thus, the eagle was the *devise* of the Roman emperors; P. Q. R. was the *devise* of the Roman people, and still continues to be what they call the *significatio* of the city of Rome.

The first *devises* were mere letters distributed on the borders of the liveries, housings, and banners, and at length on the shields. Thus the K was the *devise* of the French kings of the name of Charles, from Charles V. to Charles IX.

There were also *devises* by rebuses, equivocal, or allusions, both to names and arms. The dukes of Guise took

took for their *device* an A in an O, to signify, *ebat in A* *jan* *teur*, everyone in his turn: and the house of Senefai, in *virtute* *et* *honore* *sempiterni*: sense, that had towers in their arms, *turris mea Deus*, &c.

There are also enigmatical *devices*: as that of the Golden Fleece, with *aurum aurari*; intimating, that Philip the Good, who instituted that order, renounced every other woman, but Isabella of Portugal, whom he then married. *Devices* sometimes contain entire proverbs: as that of Cesar Borgia, *aut Cesar, aut nihil*.

The word *device* is formed from the Latin *dividere*, and was applied to the things just mentioned, as well as those hereafter mentioned, because they serve to divide, separate, and distinguish persons, parties, &c. Father Menestier differs, that there are as many different kinds of *devices*, as there are different manners of distinguishing one another, or as there are simple figures, or words, capable of expressing qualities, offices, virtues, actions, &c. of persons; and of notifying, or distinguishing them from others.

Device is now taken, in a more restrained sense, for an emblem; or a representation of some natural body, with a motto, or sentence, applied in a figurative sense to the advantage of some person.

Father Bouhours gives an accurate explication of the word *device*, in an extract inserted in the *Memoires* de Trévoux. A *device*, says he, is a composition, or assemblage, of figures drawn from nature and art, called the *body*; and of a few words adapted to the figure called the *soul*: such a compound, adds he, we make use of to denote our thoughts, or intention, by comparison: for the essence of the *device* consists in a comparison taken from nature, or art, and founded on a metaphor.

This he illustrates in the following instance: a young nobleman, of great courage and ambition, bore, for his *device*, in the last crusade at the court of France, a rocket mounted in the air, with this Italian motto, *per deum, parvo incensu; may I last but a short time, provided I mount high*: which may be explained thus; as the rocket rises a great pitch, though it only endures a little while, so it does not concern me to live long, provided I attain to glory and eminence; which is a just comparison.

On this footing, a *device*, to define it rightly, is, a painted metaphor; or, rather, an enigma inverted: for, whereas enigmas represent nature, or art, by the events of history, and the adventures of fables; a *device* is, a representation of human qualities by natural, or artificial bodies.

Thus, to express the character of Louis XIV. a sun was painted; which yet, luminous as it is, has more power than lustre: and the better to determine the sense of the painting to this signification, the Castilian motto is added; *Mai virtus quæ lucet*. The personal merit of Mary, queen of Scots, was represented by a pomgranate, with these words; *Non proxi a'j' par de ma assem*: and the talent of an apothecary person, who became all things to all men, by a looking-glass, with these words of St. Paul, *Omnia omnia*.

Devices are used on coins, counters, seals, shields, triumphal arches, artificial fire-works, and other solemnities. They are a set of images, very pertinent and artfully representing the enterprises and intrigues of war, love, piety, study, fortune, &c.

The French have distinguished themselves in this way, especially since the time of cardinal Mazarin, who had a wonderful fancy for *devices*.

The Italians have reduced the making of *devices* into an art, and laid down laws and rules for this purpose. Some of the principal are, 1. That there be nothing monstrous, or extravagant, in the figures; and nothing contrary to the nature of things, or to the common opinion of mankind. 2. That figures be not joined which have no affinity, or relation, to each other: the metaphor being to be founded on something real, and not on hazard, or imagination, excepting some whimsical combinations established in mythology, which custom, and the authority of the poets have made pass for natural. 3. That the human body be never taken into *devices*; as this would be to compare a man with himself. 4. That there be a sort of unity in the figures which compose the body: we do not mean, that there must only be a simple figure; but that, if there be several, they must have a relation and subordination to each other, so that there be one principal figure whereon all the rest depend: though still the lesser figures there are in the body of the *device*, and the less they are confused, the more perfect and elegant is the *device*. 5. The motto, which is to animate the figure, must agree so accurately thereto, as that it could not serve for any other. 6. Nothing is to be named that appears to the eye, and which the bare inspection might notify. 7. The motto is to have a complete sense of itself, for, being to make a compound with the figure it must only be a part, and, consequently, must not fig-

nify the whole. If the words alone have a complete signification, you have a full and distinct notion independently of the figure; whereas the signification should result from both. 8. The shorter the motto, the more beautiful: and a suspension of the sense, which leaves somewhat to guess, is one of the principal graces of the *device*. Lastly, it is accounted a happiness, where the words of a poet are applied in a sense which he never dreamed of, and yet so pertinently, that it should seem they had been intended for the same.

Devise, or *Devise*, in *Common Law*, the act whereby a testator gives, or bequeaths, his lands, or goods, by his last will, in writing. Though, in strictness, a *devise* of goods is more properly termed a bequest.

He who makes the *devise*, is called the *devisee*; and he to whom it is made, the *devisee*.

The words of a will the law interprets in a larger, and more favourable sense, than those of a deed: for if land be *devise*d to a man to have to him for ever, or to have to him, and his assigns; in those cases, the *devisee* shall have a fee-simple: yet if given in the same manner by feoffment, he shall have but an estate for life. So, if one *devise* land to an infant in his mother's belly, it is a good and valid *devise*; though it is otherwise by feoffment, grant, or gift. For, in those cases, there ought to be one of ability to receive presently; otherwise it is void. See *DEED*, and *WILL*.

Devise, *Executive*. See *EXECUTORY devise*.

DEUNX, a division of the Roman libra, or pound, containing eleven ounces; or eleven twelfths of any thing. See *AN*.

DEVOIRS of *Calais*, in our *Old Statutes*, customs due to the king for merchandise brought to, or carried out of Calais, when our staple was there. 34 Edw. III. c. 18. and 2 Rich. II. stat. 1. c. 3.

Devour is French, signifying *devour*.

DEVOLVED, something acquired by right of devolution. Such a right is *devolved* to the crown: such an estate *devolved* on M— by the death of N—.

The word is also used for a right, acquired by a superior, of conferring a benefice, when the inferior, and ordinary collator, has neglected to confer, or has conferred it on an unqualified person.

If a patron neglects to present a benefice in six months, the presentation lapses, or *devolves*, upon the bishop, from thence to the primate, and from thence to the king.

DEVOLUTION, in the *French Law*, a right acquired by descent, or succession, from degree to degree.

Devolution, in general, is an impediment provided by the customs of several provinces, whereby the husband who survives his wife, or the wife surviving her husband, is prohibited to alienate the real and immovable effects of the deceased, and obliged to preserve them for the children issued from that marriage; so that they may succeed thereto in exclusion of those born of a second marriage.

DEVOTION, of *devote*, from *devotus*, I *inseparate*, a sincere, ardent worship of God.

Mont Jure defines *devotion*, a softening and yielding heart, with an inward consolation, which the souls of believers feel in the exercises of piety.

Under the name of *devotion* are usually understood certain religious practices, which a person makes it a rule to discharge regularly; and with reason, if this exactitude be founded on solid piety; otherwise it is vanity, or superstition.

Devotion, among the Romans, was a sort of sacrifice, or ceremony, whereby they consecrated themselves to the service of some person.

The ancients had a notion, that the life of one might be redeemed by the death of another: and hence were those *devotions* so frequent for the lives of the emperors. The *devotion* of Decius, who, after devoting himself to his country, threw himself into the hands of his enemies, and was killed, is said to have gained the Romans the victory.

But *devotion* to any particular person was not known till Augustus. The day after the title Augustus had been given Octavius, Pegasus, a tribune of the people, began to say, he would devote and consecrate himself to him, as was practised among the barbarous nations; to obey him even at the expence of life, if he were commanded. His example was immediately followed by all the rest; and it came at length to be established into a custom, never to go to salute the emperor, without declaring, they were devoted to him. Augustus, though seeming to oppose this vile and infamous flattery, yet rewarded the author.

Cornelius Nepos uses the word *devotion* for a kind of punishment, consisting of direful curses and marks of infamy. See *ACCURSED*, and *EXECRATION*.

DEVOURING, in *Heraldry*. When fishes are borne in

an escutcheon, in a feeding posture, the heralds denominated it *decurving*; because fishes swallow all their food whole.

DEUTEROCANONICAL, in the *School Theology*, an appellation given to certain books of Holy Scripture, which were added to the canon after the rest; either because they were not wrote till after the compilation of the canon, or because of some disputes as to their canonical authority.

The word is Greek; being compounded of *deuteros*, second, and *canon*, canon.

The Jews, it is certain, acknowledge several books in their canon, which were put there later than the rest. They say, that, under Ezra, a great assembly of their doctors, which they call, by way of eminence, the *great synagoga*, made the collection of the sacred books, which we now have in the Hebrew Old Testament: and they agree, that they put books therein which had not been before the Babylonish captivity. Such are those of Daniel, Ezekiel, Haggai, &c. and those of Ezra and Nehemiah.

And the Romish church has since added others to the canon, that were not, nor could be, in the canon of the Jews; because some of them were not composed till after the canon was formed. Such is the book of *Ecclesiasticus*; with several of the apocryphal books, as that of the *Macabees*, *Wisdom*, &c. Others were added still later, because their canonical authority had not been yet examined; and, till such examination, and judgment, they might be set aside, at pleasure.

But since that church has pronounced as to the canonical authority of these books, there is no more room now for her members to doubt of them than there was for the Jews to doubt of those of the canon of Ezra: and the *deutero-canonical* books are with them, as canonical as the *protocanonical*; the only difference between them consisting in this, that the canonical authority of the one was not generally known, examined, and settled, so soon as that of the others.

The *deutero-canonical* books, in the modern canon, are, the book of *Ethier*, either the whole, or at least the seven last chapters of it; the *Epistle to the Hebrews*; that of *James*; and that of *Jude*; the second of *St. Peter*; the second and third of *St. John*; and the *Revelation*. The *deutero-canonical* parts of books are, the hymn of the three children; the prayer of *Azariah*; the histories of *Susanna*, of *Bel and the dragon*; the last chapter of *St. Mark*; the bloody sweat, and the appearance of the angel, related in *St. Luke*, chap. xxii. and the history of the adulterous woman in *St. John*, chap. viii. See **CANON**.

DEUTERONOMY, one of the sacred books of the Old Testament; being the fifth book of the **LAW**, and the last of those written by *Moses*, closing, according to the computation of *Usher*, the history of 2552½ years, from the beginning of the world to the death of *Moses*. The word is Greek; compounded of *deuteros*, second, and *nomos*, law.

It does not appear that *Moses* made any division of what he wrote, into books; or that he gave different names and titles to the different parts of his work; nor do the Jews, even at this day, distinguish them in the copies they use in the synagogues, but write them all running as one single work, without any other distinction beside that of little and great paragraphs. It is true, in the other copies, used by private persons, they are divided into five parts, as among us; but they give them no other name, but the first word wherewith each division begins; much as we do in quoting a decree, or chapter, of the canon law.

Thus, the first part of *Moses*'s work they call *בראשית* *Bereschit*, because beginning with that word; the second they call *שמות* *Shemot* and *וילל* *Vellah* *Schemoth*; the third, *ויקרא* *Vajikra*; the fourth, *ויקרא* *Vajikra*; and the fifth, *וילל* *Vellah* *Schemoth*; which is one of the first words thereof. This custom is very ancient among the rabbins, as appears from the ancient commentaries on those books, called *בראשית* *Rabba*, *שמות* *Rabba*, *ויקרא* *Rabba*, *וילל* *Rabba*, &c. and from the *Prologus galatius* of *St. Jerom*. The Greeks, when they first translated the law, gave the five parts, into which it was divided, the names of *Genesis*, *Exodus*, *Leviticus*, *Numbers*, and *Deuteronomy*. Accordingly, the names are Greek, excepting that of *Leviticus*, which is Hebrew; and they express what is contained in those books, or at least the most remarkable things contained therein: which is the usual Greek manner of giving titles.

The book of *Deuteronomy* was so called, because this last part of the work of *Moses* comprehends a repetition, or recapitulation, which that legislator made to the Israelites, before his death, of the law he had before delivered

to them at large: and hence *Deuteronomy* is still called, by the rabbins, *משנה תורה* *Mishnah Tora*; repetition of the law, second law: they likewise call it *ספר חינוך* *Sepher Chinoch* the *Books of Reprimand*; on account of the twenty-eighth chapter, which is full of blessings, promised to such as keep the law; and of curses, threatened to such as transgress it.

The book of *Deuteronomy* was written in the fortieth year after the delivery from Egypt, in the country of the Moabites beyond Jordan; *Moses* being then in the 120th year of his age. It contains, in Hebrew, eleven paragraphs, though only ten in the editions of the rabbins at Venice; twenty chapters, and 955 verses. In the Greek, Latin, and other versions, it contains thirty-four chapters: the last was not written by *Moses*. Some say, it was added by *Joshua*, immediately after *Moses*'s death: others will have it added by *Ezra*, which is the most probable opinion; who likewise made some interpolations in the book itself, as chap. ii. ver. 12. chap. iii. 11, and 14.

DEUTEROPOTMI, *Δευτεροποτμια*, from *deuteros*, second, and *potmos*, fortress, or more; among the Athenians, a designation given to such who had been thought dead, and, after the celebration of the funeral rites, unexpectedly recovered. It was unlawful for the *deuteropotmi* to enter into the temple of the *Eumenides*, or to be admitted to the holy rites, till after they were purified by being let through the lap of a woman's gown, that they might seem to be new born. *Pott. Archæol. Græc. tom. i. lib. ii. cap. 4. p. 223.*

DEUTEROSIS, the Greek name by which the Jews called their *MISHNA*, or second law. *Deuterosis* in Greek has the same signification almost as *mishna* in Hebrew; both signify an iteration. *Eusebius* accuses the Jews with corrupting the true sense of Scripture with the trifling explanation of their *deuterosis*. *Calmet, Dict. Bibl. in voc.*

DEVIDER, in the *Mange*, is applied to a horse, that upon working upon *cols* make his shoulders go too fast for the crops to follow; so that instead of going upon two tracks, as he ought, he endeavours to go only upon one. This comes from the reluctance he makes in descending against the heels; or from the fault of the horseman, who is too hasty with his hand. See **HASTE**.

DEW, *ros*, a thin, light, insensible mist, or rain, ascending with a slow motion, and falling while the fan is below the horizon.

Casaubon derives the word from the Greek *δew*, *I moisten*.

Naturalists usually rank dew among the number of meteors of the watery kind. Some define it a vapour liquified, and let fall in drops; others, a vapour having a like relation to frost, as rain has to snow, &c. Among the dissertations of *Monf. Huet*, is a letter to show that dew does not fall but rises. *M. Gerfen* likewise adopted the same opinion. To us dew appears only to differ from rain as more, and less. Its origin, and matter, no doubt, is from the vapours, and exhalations of the earth and water, raised as shown under the article *EVAPORATION*, where the theory of its ascent and precipitation is particularly explained.

M. du Fay made several experiments, first with glasses, and then with pieces of cloth, fastened to two ladders, joined at top, and spreading wide at bottom, and reaching about thirty-two feet high, in order to evince the ascent of dew; and he found that the lower bodies, with their under surfaces, were wetted before those that were placed higher, or their upper surfaces. Both *M. du Fay*, and *M. Muschenbroek*, exposed several different substances to the same dew, and found that they received and charged themselves with it in a very different manner; some more, others less, and some even not at all. The drops assumed themselves, by a kind of election, to glass and crystals, but not to metals. Mercury was exposed in a china plate; and the dew run in streams on the edges of the plate, while the least drop did not appear on the mercury. *Muschenbroek* has observed, that bodies of different colours attract the dew differently, and that this difference of attractive force depends on the structure and size of the coloured bodies. *Mem. Acad. Sc. 1736*, and *Muschenbroek, &c. ubi infra*.

From the principles proposed and illustrated, under the article *EVAPORATION*, the several phenomena of dew are easily accounted for. Hence, e. g. it is, that dew is more copious in the spring, than in the other seasons; there being then a greater stock of vapour in readiness, through the small expanse thereof in the winter's cold and frost, than at other times. Hence, what *Pliny* relates of Egypt, that it abounds in dew throughout all the heats of summer; for the air there being too hot to dissipate the vapours in the day-time, they never gather into clouds, and hence they have no rain; but we know, that

that in climates where the days are excessive hot, the nights are remarkably cold; so that the vapours raised after sun-set are readily condensed into dew.

The quantity and quality of the ascending dew in particular places depend on a variety of circumstances, as the situation, the nature of the soil, the state of the air, and the season of the year. Chemists, in analysing it, have found that it is a kind of chaos of various substances: some dew has afforded a liquor, by distillation, which struck the colours of the rainbow on glass, so strong as not to be affected by friction, alkaline lixivi-ums, or aqua regia: it also burnt like spirits of wine. Other distilled dew, having been digested with a gentle heat for eight days, and then rectified six times over, till it was exceeding subtle, is said to have broke three glasses successively; though it still remained perfectly insipid. It is natural to conclude, from the different substances which are combined with dew, that it must be either salutary or injurious both to plants and animals.

It is not easy to ascertain the quantity of dew that arises every night, or in the whole year, because of the winds which disperse it, the rains which carry it down, and other inconveniences; but it rises in greater abundance after rain than after dry weather, and in warm countries than in cold. There are some places in which dew is observed only to ascend, and not to fall; and others in which it is carried upwards in greater plenty than downwards, being dispersed by the winds.

Dr. Hales made some experiments, in order to determine the quantity of dew that falls in the night, for this purpose, Aug. 15. P. M. he filled two glazed earthen pans, three inches deep and twelve inches diameter in surface, with moist earth: and he observes, that the moister the earth, the more dew falls on it in a night; and that more than a double quantity of dew falls on a surface of water, than on an equal surface of moist earth. These pans increased in weight by the night's dew, 180 grains; and decreased in weight by the evaporation of the day, 1 ounce, 282 grains: so that 540 grains more are evaporated from the earth every 24 hours in summer, than the dew that falls in the night; i. e. in 21 days near 26 ounces from a circular area of a foot diameter. If 180 grains of dew, falling in a night on such an area, which is equal to 113 square inches, be equally spread on the surface, its depth will be $\frac{1}{113}$ th part of an inch,

$\frac{180}{113} = 1.59$. He likewise found the depth of dew in a winter's night to be the $\frac{1}{113}$ th part of an inch. If therefore we allow 150 nights for the extent of the summer's dew, it will in that time arise to one inch depth; and reckoning the remaining 206 nights for the extent of the winter's dew, it will produce 2.28 inches depth; and the dew of the whole year will amount to 3.28 inches depth. But the quantity, which evaporated in a fair summer's day from the same surface, being 1 ounce and 282 grains, gives $\frac{1}{113}$ th part of an inch depth for evaporation, which is four times as much as fell at night. Dr. Hales observes that the evaporation of a winter's day is nearly the same as in a summer's day, the earth's greater moisture in winter answering to the sun's greater heat in summer. Hales's Vegetable Statics, vol. i. p. 52, See ed. 4th. See EVAPORATION.

Signior Beccaria made several experiments to demonstrate the existence of the electricity that is produced by dew. He observes in general, that such electricity took place in clear and dry weather, during which no strong wind prevailed; and that it depends on the quantity of the dew; as the electricity of the rain depends on the quantity of rain. He has sometimes found it to begin before sun-set; at other times not till eleven o'clock at night. Artificial Electricity, Eng. ed. Appendix, Letter iii. p. 466.

The dew of plants is probably only the moisture that continually exhales through the orifices of their vessels, and not a vapour collected by their leaves: for this dew is exsired by each plant, according to the peculiar structure of its vessels, and the situation of their orifices. Plants likewise that have been shut up in vessels, and covered by glasses, have collected a greater quantity of dew in the night, than those that stood in the open air; and farther the drops are gathered in those parts, where the orifices of the vessels are manifestly open, and not all over the leaves, and not in the upper or lower leaves only, which would be the case if they arose from ambient vapour, but in all the leaves, without distinction. The oil or better dew, which is sometimes exhaled in summer by trees and herbs, and which has been found to settle on the oak, &c. is of this kind. Muschenbroeck's Baromet. Phil. Nat. vol. ii. p. 987. 993. ed. 1772. See PERSPIRATION OF PLANTS.

Substances of a very different kind from the usual and natural manner of the dew, have sometimes fallen in

that form. Our Philosophical Transactions give an account, that in the year 1693, there fell in Ireland, in several parts of the provinces of Leinster and Munster, for a considerable part of the winter and spring, a fatty substance, resembling butter, instead of the common dew; it was of a creamy texture, and dark yellow colour; and was, from its great resemblance, generally called dew-butter by the country people. It always fell in the night, and chiefly in the moist low grounds, and was found hanging on the tops of the grass, and on the thatch of the houses of the poor people. It was seldom observed to fall twice in the same place, and usually wherever it fell it lay a fortnight upon the ground before it changed colour, but after that it gradually dried up, and became black. The cattle fed in the fields where it lay as well as in others, and received no hurt from it: it fell in places of the bigness of one's finger-end, but they were dispersed scattering about, and it had an offensive smell, like that of a church-yard. There were in the same places very thick fogs during the winter, and some people supposed this no other than a sediment or collection of the heavier matter of those fogs. It would not keep very long, but it never bred worms. The country people willing to have some good of it, tried to use their children's fore heads, and it always cured them. Phil. Trans. N° 220. p. 122.

Dew, crystalline, a term used by some modern writers, to express certain dew, or fumes, which, in their fall upon the earth, become, as they say, crystals. Whatever the crystals are, which authors seem to suppose to have been generated in this manner, it is very certain, that they have in reality another origin; and these are only the accounts of ignorant and inconsiderate people. Phil. Trans. N° 329.

Dew, Moss. The dew that falls in the beginning of summer, particularly in this month, has great virtues attributed to it by many authors, when newly gathered and clean filtered. It is not of a watery appearance, or colourless, but is yellowish, and much resembles the urine of a healthy person. It is used for whitening linen and wax. The common methods of putrefying water have no effect on dew. Several quantities of it have been placed in digestion with different degrees of heat, from that of dung to that of a sand-furnace, but no putrefaction was brought on it, though continued two months together; the heat, in whatever degree, serving to purify it, nor to hurt it. The fumes, too, for all the hot months together, has no more effect on it. It only sends out a green vegetable matter of the consensu kind, which floats on the surface, and adheres to the sides of the vessel, and the whole quantity of the liquor remains as pure as before.

Though these common methods of putrefaction do not take place in this fluid, a much more simple process will. If a quantity of it be put into an open wooden vessel, and set in a cool shady place, with a canvas stretched over it to keep out dust and insects, it will in three or four weeks putrefy and stink, and deposit a large quantity of a black and thick mud. The manner of the formation of this sediment is this: a small quantity of a foul matter first separates itself from the liquor, and floats at the top in form of a skin or film; this soon after precipitates itself to the bottom, and another succeeds in its place at the top, which is soon after precipitated in the same manner. Thus the mud is a congeries of these films one on another. If a quantity of dew be put into a long and narrow glass vessel, these films, instead of sinking as soon as formed, will combine one with another at the top, and form a thick scum, which may be taken off with a spoon, and is very different from the black mud, separated to the bottom in the former experiment, being a white and thick slime: if a quantity of this be put into a drinking-glass, or other such vessel, and the water drained from it, it will somewhat shrink in twelve hours standing, and will become so solid as to take the form of the glass, and may be shook out; it then resembles a lump of boiled white starch, but is somewhat more transparent.

We have, in the Philosophical Transactions, very odd accounts of productions of the animal kingdom, in the same dew; which might puzzle any one not versed in experiments of this kind with other fluids. In one of the vessels of this dew were found millepedes, differing from the common kind in some particulars; these were the common water millepedes: and in another, a quantity of green matter, probably a consensu, with numerous eulæ of insects inhabiting it; for in a few days there were produced from this a vast number of flies. Another quantity of the dew, set in an open glass, was found after some days filled with the eulæ of the common goat, and the flies were hatched from these. Phil. Trans. N° 3.

It is easy for a bad philosopher to infer from these ac-

counts the equivocal generation of these creatures in the water; but the insight we have had into the wonders of nature in the insect world are such, that at present we know their generation to be in many species, particularly in the goat and fly kinds, from the eggs of their parents deposited in water, or any watery fluids, and that common ditch-water will at any time do what the dew does in this experiment.

There is a spirit drawn from *May dew*, which has wonderful virtues attributed to it. The method of collecting and preparing it is prescribed by Hanneman, physician at Kiel. The dew is to be gathered in clean linen cloths, exposed to the sun in close phials; then distilled, and the spirit thrown upon the caput mortuum; this is to be repeated till the earth unite with the spirit, and become liquid; which happens about the seventh or eighth cohabitation, or distillation. By such means you gain a very red odoriferous spirit. Stönerfoht, a physician of Lubec, thinks *May dew* should be gathered in glass plates, especially in still weather, and before sun rise. And Emmuler is of the same opinion. It might likewise be collected with a glass funnel, exposed to the air, having a crooked neck to bring the dew into a phial in a chamber. See Phil. Trans. N.º 3. Hoffmann, and others. It is apparently from the preparation of this dew, that the brothers of the Rosicrucians took their denomination.

Dew, in *Chemistry*, a name formerly given to the phlegm that rose first in the distillation of several substances. Thus, the dew of vitriol, and the dew of honey, were watery liquors, which rose first when these substances were distilled.

Dew, orange. See ORANGE.

Dew, June. See SUMMER.

Dew, earth of. See EARTH.

Dew-horn, in the Management of Cattle, an excessive swelling of the body, proceeding from the greediness of a beast to feed, when put into rank pasture.

This swelling is often so great that the creature runs the utmost hazard of bursting; in which case it should be made to stir much, and purge well; but the proper cure is to bleed the creature in the tail, then putting a nutmeg into an egg, to thrust it down the creature's throat, shell and all; after which, by walking him up and down, he will soon recover.

Dew-lap, the flesh that hangs down from the throat of oxen.

DEWBERRY-*apple*. See RASPBERRY.

DEX, a name used by many Greek writers, for a worm or maggot, hatched of the egg of a beetle, and remarkable for its eroding wood. It is also called thrips and exylon. The old Greeks used the pieces of wood eroded by it in various directions as seals. See THRIPI.

DEXTANS, in *Anatomy*. See AS.

DEXTER, in *Heraldry*, is applied to the right side, as *sinister* is to the left.

DEXTER-dors, is the right side of the hafe.

DEXTER-chief, the angle on the right hand of the chief.

DEXTER-pant. See POINT.

The word is pure Latin, signifying right-handed; whence the word *dexterity* for address and ability in the performing of any thing.

DEXTRARIUS, is understood of one who takes the right-hand of another; and the word *dextrarii* has been used for light horses, or horses for the great saddle; from the French *dextris*, a horse for service.

DEXTROCHERE, or **DESTROCHERE**, in *Heraldry*, is applied to the right-arm, painted in a shield, sometimes naked, sometimes clothed, or adorned with a bracelet, and sometimes armed, or holding some moveable, or member used in the arms.

The word is formed from the Latin *dextrachium*, which signifies a bracelet worn on the right wrist, mentioned in the Acts of the Martyrdom of St. Agnes, and the Life of the Emperor Maximus.

The *dextrachere* is sometimes placed as the crest.

DEY, the title of the sovereign of Algiers, under the protection of the grand seignior. A prince under this title was appointed by the sultan, at the request of the Turkish soldiers, in the year 1710. The term *dey*, in the Turkish language, signifies an uncle by the mother's side; and the reason of the denomination is this; that the Turkish military consider the grand seignior as their father, the republic as their mother, by which they are nourished and maintained, and the *dey* as the brother of the republic, and consequently the uncle of all who are under his dominion. Besides the age, experience, and valour, which are necessary qualifications of a person to be elected, he must also be a native Turk, and have made the voyage to Mecca. He has no guards, nor considerable retinue; he presides at the divan, and is most distinguished by the respect and submission which are paid him.

DIA, *dia*, the beginning of divers terms in medicine, chi-

rurgery, pharmacy, &c. Where these three letters commence the name of a remedy, ointment, plaster, cataplasma, &c. they signify composition and mixture; as in *diapalma*, *diachylon*, &c.

DIA is likewise the beginning of many terms in the other arts; as, *diameter*, *dialogue*, &c. on all which occasions, *dia*, which is an inseparable particle, or preposition, is borrowed from the Greek *dia*, *ex*, or *in*; which begins the same words in the Greek.

Indeed we have words wherein *dia* is no preposition borrowed from a foreign language; though it is possible, the words themselves may; as in *diamond*, *dial*, &c.

DIA, in *Mythology*, a goddess among the Romans, probably the same with *CYBELE*.

DIABATHRA, in *Antiquity*, a kind of shoe worn by the Grecian women. *Plut. Lex. Ant. in voc.*

DIABE, in *lebbey-ware*, the name of a prickly-fet-fish of the orbis or globe-fish kind, and in all things resembling the hiltux or porcupine-fish, except that its spines or prickles are all fixed into its skin by three interstices.

DIABETES, *diabeta*, in *Medicine*, a hasty and profuse evacuation of the drink by the urinary passages, accompanied with an ardent thirst, and leanings of the whole body.

This word is derived from the Greek *diabaino*, to pass, or pass quick.

The drink, thus discharged, is usually a little altered from what it was when taken down, and turned chylous, and milky; but sometimes not at all.

The *diabetes* seems owing to a too great laxity of the fibres of the arteries of the kidneys; or too great a quantity of sharp salts in the blood, which dissolve the mass of blood, or disunite the parts thereof, so that the serosity is easily separated from the thicker parts.

According to Quincy, the evident, and most common cause of the *diabetes* is the too great use of spirituous liquors, wherewith the serum becomes so impregnated, that it will not attract, and join with the cruer, or globules of the blood, but runs off through the kidneys, sweet or insipid.

It happens most frequently to those who, without due exercise, indulge themselves with drinking vinous liquors, and then quench their thirst arising from thence by too great a quantity of such as are cooling.

In this disease the urine is thin and pellucid, and has no sediment, and is of a sweetish taste; though cases have occurred, in which it has not had this taste; the quantity voided is always very great; and if the patient endeavour to retain it, they are afflicted with feelings about the loins, and a sensation of weight and stiffness in the hypochondria. It is attended with thirst, a hectic heat, a weak but quick pulse, and a gradual wasting of the flesh.

Persons subject to the diabetes. It is a very rare disease, and seems to have been so in other ages as well as in later times. Galen expressly says, that he never met with more than two persons who had it; the people affected with it are usually such as have disorders of the viscera in general; and it is often but a symptomatic affection, arising from an improper treatment of persons in fevers.

Prognostic in it. It is always a very terrible disease, but the longer standing it is of, the more difficult it is to be cured; it is not, however, suddenly of fatal consequence, but the people usually live some time with it, though they in the end generally die tabid, after having been afflicted with it for a length of time.

Method of cure. The infarctions of the viscera, which are the occasion of this, are first to be regarded, and are to be attacked with such aperients as are not strongly diuretic; of this kind are decoctions of the roots of dandelion, fucus, polypody, and the like, and of the cassia herb. Fills also are to be taken, made of anemolium, and the other resolvent gums, with the bitter extractions, and interchangeably with these the digestive neutral sales, such as tartarum vitriolatum, and the like. During this course, the febrile heat, which always attends this disorder, is to be taken off by the vegetable acids, such as sorrel and pashan, and tinctura of roses made in the usual way. Some recommend the tellaceous powders, in general; and others are peculiarly lavish in the praises of craw-fish, reduced to powder whole, after baking them in an oven. The great discharge of urine is to be lessened, in the mean time, by gentle laxatives now and then given, such as infusions of fennel, rhubarb, and the like; and finally, if the disease goes off, or remains considerably of its violence, the chalybeates, and other restoratives, are to be given, to restore the parts to their due state. It is a common error to give astringents in a *diabetes*; for, if they take effect, they too violently constrict the viscera, and bring on pains and swellings in the loins, and not rarely an asthma and death itself in the end.

Persons subject to this disease should be extremely care-

ful of themselves in their regimen; they should avoid all hot things, and beware of themselves that they do not fall into violent passions; they should feed principally on emulsive and gelatinous diet, to make up for the waste of flesh that always attends this disease. Junker's Consf. Med. p. 540.

The bark, lime-water, Bristol-water, and antimonials combined with the *diacetra thebica*, have been recommended and used for the cure of this disorder. Moderate exercise, and friction of the body are useful.

Dr. Morgan thinks the tincture of cantharides may almost be absolutely depended on for stopping the immediate flow of urine in the *diabetes*. The way he prepares his tincture is, by infusing half an ounce of cantharides upon a pound of the elixir vinioli; of which undure, from fifteen to thirty or forty drops, may be given twice or thrice a day in Bristol hot-well water. Mechan. Pract. of Phys. p. 114.

Dr. Jurin found the chalybeate waters acidulated with the oil of sulphur, very successful in this distemper. Med. Eff. Edinb. abr. vol. ii. p. 469.

Alum-poultice drink is also said to be an effectual cure for a *diabetes*. Ibid.

According to Dr. Mead, the *diabetes* is a disease of the liver, and not of the secretory vessels of the kidneys; as has been generally thought. See Monit. & Pract. Medic. cap. ix. sect. 2. and Mechanic Account of Poisons, Essay i. ed. 4.

The doctor recommends the following medicine as efficacious in this distemper: take four pints of milk, boil it a little, and turn it with three drachms of alum; four ounces of this should be taken three times a day at least. Dr. Brocklesby attributes great efficacy, in a case where he was concerned, to alum whey, made by boiling from fifty to thirty grains of powdered roche alum, in a sufficient quantity of new milk from the cow, to afford a full pint of whey; half of which was drunk by the patient every night and morning, for six weeks. Med. Obs. vol. iii. p. 279.

Dr. Dobson, of Liverpool, made several experiments, in order to ascertain the nature of this disease; and he considers it as a species of imperfect digestion or assimilation, and to be more a disease of the system in general, than either of the liver or kidneys. On this system he accounts for the different taste of the urine in different subjects, the emaciating effects of this disease, the acid sweats, and the sensation of hunger that attend it. From hence he infers, that the obvious indications of cure, are to strengthen the digestive powers, to promote a due sanguification, and to establish a perfect assimilation through the whole economy. Med. Obs. vol. v. art. 27.

There is another kind of *diabetes*, wherein the person affected renders a great deal more by urine than he drinks, nay, sometimes more than he both eats and drinks. Some physicians attribute this excessive quantity of liquor to the air he respites, which, they suppose, becomes converted into water; or, at least, the water in the air respired is here absorbed, and collected. But others, with more probability, attribute it to a coagulation of the blood, fat, and even the solid parts of the body.

DIABETES, in *Hydraulics*, is applied to a siphon, the two legs or branches whereof are inclosed in one another; as in the glass described by Hero, which runs itself quite empty, without being inverted, as soon as the water is arrived at the height of the upper branch of the siphon.

DIABOLUS marinus. See *SER-DEVIL*.

DIABOTANUM, from *dia* and *botan*, herb, in *Pharmacy* and *Chirurgery*, denotes a plaster of herbs, wherewith wens, &c. are resolved and dissipated. The *diabotanum* is sovereign for the hydatides.

DIABROSIS, in *Medicine*, a solution of the continuity of a part, caused by sharp, corrosive humours, gnawing and devouring the flesh.

The word is Greek, compounded of *dia*, per, through, and *brusis*, to eat.

DIACARTHAMI, in *Pharmacy*, an electary composed, of turbit, manna, scammony, hermodactyls, and other purgatives; with the addition of the pulp of the seed of the *carthamus*, which gives it the denomination.

Diacarthami chiefly purges *pituita*. It was formerly prescribed in diseases of the brain, and frequently mixed in medicines along with other purgatives, but is now wholly out of use.

DIACARYON, or *DIANUCUM*, in *Pharmacy*. See *DIANUCUM*.

The word is formed from *dia*, and *nucum*, walnut. Galen is said to have prepared his *diacaryon* with the juice of walnuts, mixed with as much honey as sufficed to render it an agreeable composition.

DIACAUSTIC curve, or *caustic by REFRACTION*, is a species of caustic curves, whose genesis may be thus conceived.

Imagine an infinite number of rays, as B A, B M, B D, &c. (Tab. Geom. fig. 20.) issuing from the same luminous point, B, to be refracted from or to the perpendicular M C, in the curve A M D; and so as that C E, the lines of the angles of incidence C M E be always to C G, the lines of the refracted angles C M G, in a given ratio: then the curve line, which touches all the refracted rays, is called the *diacaulis*.

DIACELTATESSON, in *Chemistry*, a name given by Van Helmont, to a purging preparation, procured from the fixed flowers of antimony, in the following manner: take eighteen grains of the fixed diaphoretic flowers of antimony, sixteen grains of resin of scammony, and seven grains of cream of tartar, make altogether into a powder. Or take nine grains of the fixed antimony, nine grains of resin of scammony, and three grains of cream of tartar, make them into a fine powder. The former is the largest dose for a grown person, and the latter the least; they are to be taken without any acid; and if they operate too violently, the violence may be stopped by taking any thing acid: it is to be given in intermittents, so as to finish its operation immediately before the coming on of the fit: it is said by the author always to cure quartans before the fourth dose, and all intermittent and continued fevers.

Boerhaave observes, that he had often given it with good effects, but never with that great success which the author ascribes to it; who says, that it radically cures the gout and fevers, heals ulcers of the larynx, œsophagus, and bladder, and purges the body when in perfect health, but not otherwise. This candid writer observes, that Helmont seems always to have carried the virtues of his medicines by a subtilty of reasoning, beyond what will be found warrantable of them from experience. Boerh. Chem. part ii. p. 338.

DIACENTROS, from *dia*, through, and *centros*, centre, is used by Kepler to signify the shortest diameter of the elliptical orbit of any planet; probably because it passed through the centre, and not through the focus, which distinguishes it from the longer diameter.

DIACHALASIS, from *diachalao*, to be relaxed, in the *Medical Works of the Ancients*, a term used to express a solution of continuity in the bones of the cranium at the sutures; that is, when the bones recede from their mutual indentation, an accident that frequently happens from large wounds in the head.

DIACHALCITIS, in *Chirurgery* and *Pharmacy*, a plaster which formerly used to be applied after the amputation of a cancer, and on many other occasions.

The *emplastrum diachalcitidis* is composed of oil, axungia, and chalcitis, from the last of which drugs it derives its name.

DIACHRISTA, from *dia* and *chris*, I anoint, a name given by the ancient writers in medicine to certain compositions, whose use was to be applied to the fauces, uvula, palate, and tongue, for the absterion of phlegm.

DIACHYLON, in *Pharmacy*, a name given to divers plasters, on account of the mucilages mixed therein, which are viscous juices, called by the Greeks *χυλα*, drawn from certain plants. See *MUCILAGE*.

DIACHYLON, white, or *simple*, should be compounded of common oil, litharge of gold, and mucilages drawn from marsh-mallow roots, fenugreek, and aniseeds. It is proper to soften, digest, ripen, and resolve.

The *diachylon*, called *treatum*, has for its basis the common white *diachylon*, with a pound of which, an ounce of powder of iris is mixed. This plaster digests, incises, and ripens with more force than the simple *diachylon*.

There is also the great *diachylon*, *diachylon magnum*, composed of litharge of gold, oils of orris, camomile, and dill, turpentine, resin of the pine, yellow wax, and mucilages of line and fenugreek, with new figs, raisins of Damascus, ichthyocolla, juices of orris, squills, and hyssop.

This *diachylon* softens scirrhuses, and resolves and dissipates tumors. It is called the *great*, not only on account of its extraordinary virtues, but also because composed of a greater number of ingredients than the rest.

The *DIACHYLON gummatum*, or *diachylon cum gummi*, is the great *diachylon* with the addition of gum ammoniac galbanum, and sagapenum, dissolved with wine, and boiled to the confidence of honey. This plaster is the most powerful of all for digesting, ripening, and resolving.

DIACODIUM, in *Pharmacy*, a syrup prepared from poppy-heads; called also *syrupus de meconis*.

The word is formed from the Greek *dia*, per, and *codium*, poppy-head.

The ancients had two kinds: *simple*, and *compound*.

DIACODIUM, the simple, was a kind of opiate, made of the juice expressed from the heads of white poppies, and boiled up with sugar. See *OPIATE*.

It was prescribed to soften sharp, ferrous humours, to appease

peafe coughs, and to provoke sleep. This preparation was of great use among the ancients; but it is now laid aside, since it has been found, that the syrup made of an infusion of white poppy-heads, which is what we now call *dianthum*, produces the same effect.

DIACODIUM, *compound*, was made of the *simple*, with the addition of the troches of hamec, hypocyssis, myrrh, saffron, and lalauilines. It was used to stop and soften catarrhs, hæmorrhoids, and fluxes of the belly.

DIACODUS, in *Natural History*, a name given by some to the *diadocha*, a kind of beryl or sapphir, of which many fabulous things are affirmed.

DIACOLOCYNTHUS, in *Pharmacy*, *dia anacardium*, from *anacardium*, *colocyth*, a remedy, of which colocyth is a principal ingredient. See **COLOCYTH**.

DIACONICON, *Sacristy*, a place adjoining to the ancient churches, where the sacred vestments, with the vessels, relics, and other ornaments of the altar, were preserved, answering to our vestry.

The word is Greek, formed from *diakon*, *I serve*, *I minister*, because here was kept every thing belonging to divine service. It was also called *anacardium*, and in Latin *substantium*; because it was here that the bishops received and blessed strangers. Sometimes, too, it was called *potestatum*, or *potestatum*, *missa*, on account of the tables kept therein, for disposing the sacred ornaments on, or *substantium*, a sort of inn, or house, for the lodging of soldiers.

DIACONISSA, and **DIACONATE**. See **DIACON**, and **DIACONAT**.

DIACORF, *diakon*, from *dia* and *corf*, *I cut off*, in *Grammar*, the same with what is otherwise called **THESIS**.

DIACORF, in *Surgery*, denotes a deep cut or wound; in the act of cutting off any part.

DIACORALLIUM, in *Medicine*, a preparation of coral in the London dispensatory.

DIACOUSTICS, or **DIAPHONICS**, the consideration of the properties of sound reflected in passing through different mediums; that is, out of a denser into a more subtle, or out of a more subtle into a denser medium. See **SOUND**.

The word is formed from the Greek *dia*, *per*, *through*, which intimates a passage; and *akouo*, *I hear*, *g. d.* the consideration of the passage of the sounds we hear.

DIACRII, in *Antiquity*, was the name of a party or faction at Athens.

That city, we read, was divided into two parties: the one favourers of an oligarchy, who would only have a few persons employed in the government. The other consisted of such as were for a democracy, or popular government, wherein the whole people should have a share. The first were called *diacrii*, and the latter *politi*; the latter inhabiting the lower, and the former the upper, or upper quarter, or part of the city.

The laws of Solon imported, that Pistratus should be chief of the *diacrii*; though the scholiast on Aristophanes's comedy, *The Wasps*, affirms, that Pistratus distributed the quarter of the *diacrii* among his sons, and put Lycos at their head.

DIACTORE, in *Metaphors*, a surname of Mercury; derived from *diakto*, *I attend*, because Mercury was the messenger of the gods.

DIACYDONITES, in *Pharmacy*, is applied to things and remedies, wherein quinces are a principal ingredient.

The word comes from *dia*, and *akouo*, *quince*. *Confectio diacydonites*, or *diacydonis*, is marsh-male, a confection of quinces, or wherein quinces have a chief share.

DIADELPHIA, in *Botany*, the seventeenth class of plants with hermaphrodite flowers, whose stamina, by the conjunction of their filaments, are formed into two bodies, the one standing about the pistil, and the other surrounding it. The lower part of this last is membranaceous, of a cylindrical figure, and split lengthwise on its opposite side; but the upper half terminates in nine subulate or awl-shaped parts, of which the intermediate are alternately longer and shorter by pairs. The upper filament is awl-shaped, and like a bristle, and covers the slit of the cylindrical filament incumbent on it. The anthers are ten; the pistil is single; the germens oblong and roundish; the style subulate and filiform; the stigma downy; the length of the style, and placed immediately under the anthers; the calyx is a monophyllous, campanulate, and withering perianthium; the papilionaceous corolla unequal, and its petals have distinct names, as *vexillum*, the standard, covering the rest; *ala*, the wings, which are two equal petals, one at each side of the flower, under the *vexillum*; and *carina*, the keel, which is the lowest petal, often bipartite, placed under the *vexillum* and between the *ala*; the pericarpium is an oblong, compressed, bivalve legumen, with a longitudi-

nal future both above and below; the seeds are few, roundish, smooth, fleshy, and pendulous, in a small, short, proper receptacle, thinner towards the base, and obscure at the disk that fastens them.

The word is formed of the Greek *dia*, *twice*, and *adelphos*, *brother*. Among the plants of this class are the seminary, milk-wort, broom, &c. See *Tab. of Botany*, *Class* 17.

This is a perfect natural class of plants, and is the most remarkable of all others in the structure of the flower. The common situation of the flower is an obliquely pendulous direction, or in an acute angle from a perpendicular line. The former systematists in botany, as Linnaeus observes, took great notice of the pod in this class of plants, and thought it the principal subject of distinction; but he very judiciously makes it but of very little consequence, and will not allow it sufficient to distinguish the genera one from another; but the cup, which had always before his time been disregarded, he esteems a very essential part of the plant, and sufficiently certain to erect the different genera upon in many cases. Some of the old writers had been used to take the leaves into their marks, by which to distinguish genera of this class; but Linnaeus wholly excludes this part of a plant from this office. Magnol has observed, that the calyx of the *diadelphos*, or papilionaceous flowers, is *depression*, and is composed of two distinct oblong petals, the lower edges of which join so nicely and closely together, that they seem only one; and are not joined in their substance, but only in their situation. Linnaeus has strictly examined this, and finds that the author is so far right, that this is really the case in many of the papilionaceous flowers, but not in all; since not only appearing to have, but really and certainly having a carina composed of only one petal.

The consideration of the stigma is of more consequence in this than in most other flowers, and even more than that of any other part of the fructification in this. The seeds of all the plants of this class are *estable*, excepting in a very few particulars; their leaves also are a grateful food to cattle. Lin. Gen. Plant. p. 377.

Of this class there are four orders, viz. the *pentapetalæ*, comprehending one genus; the *heptapetalæ*, two; the *decapetalæ*, two; and the *decandria*, forty-nine.

DIADLEM, *diadema*, in *Antiquity*, a head-band, or fillet, worn by kings as a badge of their royalty; while the crown was left to the gods.

The word comes from the Latin *diadema*, of the Greek *diadema*, *a little band encompassing the head*, of the verb *diako*, *enro*, *I gird*.

The *diadema* was a sort of ribbon, or fillet, worn of silk, thread, or wool, more or less broad. It was used round the temples, and forehead; the two ends being knotted behind, and let fall on the neck.

It was usually white, and quite plain, though sometimes embroidered with gold, and set with pearls, and precious stones. In later times it likewise came to be twisted round crowns, laurels, &c. and even appears to have been worn on divers parts of the body: thus Phalaris observes, that Pompey was suspected of aspiring to the royalty, because of his wearing a white garb, which was no other than a ligature for an ulcer he had on his leg, but which the people mistook for a *diadema*.

Pliny, lib. vii. cap. 5. observes, that Bacchus was the first inventor of the *diadema*. Athenæus assures us, that the topeas, and good fellows, first made use of it, to preserve themselves from the fumes of wine, by tying it tight round their heads; and that it long afterwards came to be a royal ornament.

The *diadema* remained a long time the peculiar badge of kings; at length it was assumed by the Roman emperors, as the mark of imperial dignity.

Authors are not agreed about the time when the Roman emperors first assumed the *diadema*. Some refer it to Caligula, others to Aurelian, and others to Constantine the Great. The younger Victor says, positively, that Aurelian took the *diadema*, which no emperor had dared to do before him. For though it should seem from the same writer, that Caligula had done the like, yet Suetonius assures us, he had it only in view, and that he never executed it. Hellogabalus, indeed, took a *diadema*; but it was only in the palace he wore it, and never appeared with it in public. Jordanes even goes as low as Diocletian for the introduction of the *diadema*; but it is certain, there is a medal of Aurelian, with a crown like one of our ducal crowns, which is furnished by a border of pearls, that bears a very great affinity to a *diadema*. And the authors, who have explained that medal, are all agreed that it is one. Mr. Spanheim also allows Aurelian to have taken it: his successors imitated him therein; and yet the ornament did not become common till the time of Constantine. After him the emperresses were allowed

lowed to wear it; accordingly we find them represented therewith on medals; though till that time we have no instance either of crown, or *diadem*, on a woman's head, in all the Roman empire.

An author of the fifth century, quoted by Bollandus, pretends that Constantine first wore the *diadem*, and that he only took it to bind his hair, and keep it in order. But this is not very probable; and it is certain, that at least some emperors had worn it before him, as Aurelian and Carinus.

Eusebius gives it to Constantine Chlorus, when only Caesar; which is confirmed by one of his medals, wherein he is represented with a *diadem*, adorned with rays; though even after Constantine, when the *diadem* was become the usual ornament of the Augusti, it was not always given to the Caesars. Indeed, we see it on some of the medals of Julian, while only Caesar; though it is pretty certain, he did not wear it till he became Augustus. Du-Roye will not assert, that Constantine first took the *diadem*; but only, that he first made it into a kind of oak, or clove crown, as is seen in some of his medals, and thence of his successors.

DIADREM, in *Heraldry*, is applied to certain circles or rims, serving to bind or enclose the crowns of sovereign princes; and to bear the globe, and cross, or the fleurs-de-lys, for their crest.

The crowns of sovereigns differ in this, that some are bound with a greater, and some with a less, number of *diadems*.

Prelates likewise appear to have anciently worn a sort of *diadem*: thus Baronius writes, that St. James the apostle wore a gold plate on his forehead, as a mark of his episcopal dignity.

In blazoning, the bandage about the heads of Moors, on shields, is sometimes also called *diadem*.

DIADOCCHUS, in *Natural History*, the name given by the ancients to a gem, approaching to the nature of the beryl, or *aqua-marina*, probably a pale sapphire; for they had no peculiar generic name for that gem, but called the beautiful deep-coloured ones only sky-blue beryl, beryll acordes. The writers of the middle age have given strange accounts of the magical virtues of this stone, such as in calling up spirits, and many other the like things, on being thrown into water; they said, however, that if it happened by any accident to touch a dead body it lost all its virtue.

DIADROME, from *dia* and *drōmōs*, *cursum*, is sometimes used for the vibration, motion, or swing of a pendulum.

DIAPHRYSIS, in *Surgery*, the operation of dividing and separating parts, whose union and continuity were an obstacle to the cure; or which were joined and conglutinated contrary to the order of nature.

The word, in its original Greek, *διαφύσις*, signifies *division*.

There are five ways of performing the *diaphysis*, viz. by cutting, picking, tearing, drawing, and burning.

DIAPHRYSIS is also used, in *Medicine*, for the destroying or consuming of the vessels, or canals, of an animal body; when, from some cutting, or corroding humour, certain passages are made, which naturally ought not to have been; or certain natural passages are dilated beyond their ordinary dimensions; so that the juices, which should have been contained therein, extravasate, or run out.

DIAPHYSIS, in *Grammar*, is a figure whereby a diphthong is divided into two syllables: as *aula* into *auloi*, *pitta* into *pittai*, *equa* into *equoi*.

DIAPHYSIS is also used, in a general sense, for any division of one syllable into two: as in that verse of Tibullus, *Stamina non vili dissimula deo*, for *dissimulanda*.

This is usually noted by two points placed over a letter, to show that it is to be sounded by itself, and not joined with any other so as to make it a diphthong: thus *atra*, by the points over the *a*, is distinguished from *ara*.

It is also a kind of metaphor, or addition to a word, by dividing one syllable into two: as *aula*, by a *diaphysis*, is a word of three syllables, instead of *aula*. See **TAB. III.**

DIAPHTERAE, *ἀντιστράται*, from *διὰ*, *τῆς*, *ἀντι*, among the Aboventes, were of two sorts, the clerici and diallectarii. The former were a kind of public arbitrators, chosen by lot, to determine all causes exceeding ten drachmas within their own tribes. Their office was annual, at the expiration of which they were obliged to give up their accounts; and if it was proved, that they refused to give judgment, or to have been corrupted, they were punished with infamy. Their sentence, however, was not final, an appeal lying from it to the superior courts.

The *diallectarii*, on the contrary, were private arbitrators, from whose sentence there lay no appeal; and accordingly they always took an oath to administer justice, without partiality, which the *clerici* did not. Potter's *Archæol. Græc.* lib. I. cap. 22. tom. I. p. 422, seq.

DIAGLAUCIUM, a name given by the old writers on medicine to a sort of collyrium, in which the juice of the glaucium, or yellow poppy, was a principal ingredient. It was used for beginning lippitudes and ophthalmies.

DIAGLYPHICE, from *diaglyphein*, *engraver*, the art of engraving, cutting, or otherwise working, hollow or concave figures, in metals; such as seals, intaglios, matrices, or coins for medals, &c. See **SCULPTURE**.

DIAGNOSTIC, in *Medicine*, a term applied to those signs, or symptoms, which indicate, or discover, the present state of a disease, its nature and cause.

The word is compounded of the Greek *diagno*, *per*, through, or by; and *gnosis*, *I know*.

The physicians have *diagnostic*, as well as *prognostic* signs; the first, with regard to the present state of the disease, and the patient; and the second to the future.

DIAGONAL, in *Geometry*, a right line drawn across a parallelogram, or other quadrilateral figure, from the vertex of one angle to that of another.

Such is the line FN (*Tab. Geometry*, fig. 21.) drawn from the angle P, to N.

Some authors call it *diameter*, and others the *diametral* of the figure.

It is demonstrated, 1. That every diagonal divides a parallelogram into two equal parts. 2. Two diagonals, drawn in any parallelogram, bisect each other. 3. The diagonal of a square is incommensurable with one of its sides.

Add, 4. A very noble theorem in elementary geometry, first demonstrated by Mr. Lagny, in the *Mémoires de l'Académie Royale des Sciences*, an. 1706, is, that the sum of the squares of the two diagonals of every parallelogram is equal to the sum of the squares of the four sides.

It is evident, at first sight, that the famed 47th proposition of Euclid, so richly worth the hecatomb it cost the author, is only a particular case of this proposition: for if the parallelogram be rectangled, it follows of course, that the two diagonals are equal; and of consequence, that the square of a diagonal, or, which is the same thing, the square of the hypothenuse of a right angle, is equal to the squares of the two sides. If a parallelogram be oblique-angled, and, of consequence, the two diagonals unequal, as is the more usual case, the proposition becomes of more extensive use.

The demonstration, in oblique-angled parallelograms, is thus: suppose the oblique-angled parallelogram ABCD (*Tab. Geometry*, fig. 22.) whereof BD is the greater diagonal, and AC the lesser: from the point A, of the obtuse angle DAB, let fall a perpendicular AE, to the side CD; and from the point B another perpendicular BF to the side DC. Then are the triangles ADE, BCF equal, and similar, as AD is equal to BC, and the angle ADE, BCF, as well as AED, BFC, are also equal; consequently, DE is equal to CF. Now, by Euclid, prop. 13. lib. ii. in the obtuse-angled triangle BDC, the square of the side BD is equal to the sum of the squares of BC, and CD, together with double the rectangle of CF by CD; and by the 13th, lib. ii. in the triangle DAC, the square of the side AC is equal to the sum of the squares of AD, and CD, abating double the rectangle of the same, CD, by DE, equal to CF. Consequently, the former exceeds precisely compensating this defect, the sum of the squares of the two diagonals is equal to the sum of the squares of the four sides. Q. E. D.

Hence, in every rhombus, or lozenge, knowing one side, and a diagonal; the other diagonal will likewise be known: for, as the four sides are equal, subtracting the square of the given diagonal from quadruple the square of the given side, the remainder is the square of the diagonal required.

The proposition is likewise of great use in the theory of compound motions; for, in an oblique-angled parallelogram, the greater diagonal being the subtense of an obtuse angle, and the lesser of an acute angle, which is the complement of the former, the greater will be the greater, and the less the less, as the obtuse angle is the greater; so that if the obtuse angle be conceived to increase till it be infinitely great, with regard to the acute one; or, which amounts to the same thing, if the two contiguous sides of the parallelogram be extended directly, end to end, in a right line, the great diagonal becomes the sum of the two sides, and the lesser one, nothing. Now, two contiguous sides of a parallelogram being known, together with the angle they include, it is easy to find the subtense of that angle, i. e. one of the diagonals of the parallelogram, in numbers; which done, Mr. de Lagny's proposition gives the other. Which second diagonal, thus found, is the line that would be described by a body impelled at the same time by two forces, which should have the same ratio to each other as the contiguous sides have,

have, and act in those two directions; which *diagonal* the body would describe in the same time, as it would have described either of the contiguous sides in, if only impelled by the force corresponding thereto. This is one of the great uses of the proposition; for the ratio of two forces, and the angle they make, being given, it is frequently necessary to determine, in numbers, the *line* of body, impelled by two forces, would describe in a certain time. See COMPOSITION of Motion.

All the sides of a rectilinear figure, as AB, BC, CD, DE, EA (fig. 23), and the angles O, and Y, being given, to find the *diagonal*.

In the triangle ABE, the sides AB, and AE, being given, and the angle O, the angle A is easily found by trigonometry; and, from this, the *diagonal* BE. And, after the like manner, the triangle BCD is resolved, and the *diagonal* BD found.

Since ICHNOGRAPHIES, or plans, are best taken, by having all the sides and *diagonals*, the use of this problem, in planimetry, is of some importance; especially to such as are willing to have their work accurate, though at the expense of calculation.

DIAGONAL scale. See PLOTTING-scale, and SCALE.

DIAGRAM, from *diagramma*, I describe, in Geometry, &c. a scheme for the explanation, or demonstration, of any figure, or the properties thereto belonging.

	Nete Hyperbolæon	— a	
Hyperbolæon Tetrachord	Parante Hyperbolæon	— g	
	Trite Hyperbolæon	— f	
	Nete Diezeugmenon	— e	
Diezeugmenon Tetrachord	Parante Diezeugmenon	— d	Nete Symmenon
	Trite Diezeugmenon	— c	Parante Symmenon
	Paramese	— b _a	Symmenon Tetrachord
		b _b	Trite Symmenon
	Mese	— a	Mese
Meson Tetrachord	Lichanos Meson	— G	
	Parapate Meson	— F	
	Hypate Meson	— E	
Hypaton Tetrachord	Lichanos Hypaton	— D	
	Parapate Hypaton	— C	
	Hypate Hypaton	— B	
	Proslambanomenos	— A	

It is to be observed, that this *diagram* only represents the diatonic genus; and, therefore, after the names *lichanos hypaton*, and *lichanos meson*, (some add *diatensis*), to distinguish them from the lichani of the chromatic or harmonic genera. Wallis, Append. ad Ptolem. Harm. p. 157. See LICHANOS.

The tetrachords in this *diagram* are conjunct or disjunct. The conjunct have a common note, chord, or sound. Thus the hypate meson, which is the last of the hypaton tetrachord, is the first of the meson. The mese also is the last chord of the meson, and the first of the synemmenon tetrachord. So likewise the nete diezeugmenon is the last chord of the diezeugmenon, and the first of the hyperbolæon tetrachord. The disjunct tetrachords are those which are separated by a tone. Thus the meson and diezeugmenon tetrachords are separated by the tone between the mese and paramese; so likewise the synemmenon and hyperbolæon tetrachords are separated by the tone between the nete synemmenon, and the nete diezeugmenon.

Some of the names of the chords in this *diagram* being placed nearer to each other than the rest, signify that there is only a semi-tone between them. Thus, between the hypate hypaton and the parapate hypaton, or between the mese and the trite synemmenon, or between the paramese and trite diezeugmenon, the interval is no more than a semi-tone.

It has been observed by Dr. Pepusch, that the ancients considered a descending as well as an ascending scale; the former proceeding from acute to grave precisely by

the same intervals, as the latter did from grave to acute, and the same name served for both. But the proslambanomenos, and the rest of the names, correspond to different notes of our scale. An example of one octave will explain the learned author's meaning.

Ascending	Descending
A — Proslambanomenos	— g
B — Hypate hypaton	— f
C — Parapate hypaton	— e
D — Lichanos hypaton	— d
E — Hypate meson	— c
F — Parapate meson	— b
G — Lichanos meson	— a
a — Mese	— G

The intervals here, both ascending and descending, are the same, and in the same order, viz. tone, semi-tone, tone, tone, semi-tone, tone, tone. So that the one scale is precisely the reverse of the other. This distinction of an ascending and a descending scale, is said to be conducive to the variety and perfection of melody, though little understood by modern composers. Phil. Trans. N^o 481. p. 359.

The eighteen names of the scale of the ancients do not seem

seem to signify so many distinct sounds, especially in the dactylic genus, where the paratele symmenon and the trite diezeugmenon, as also the nete symmenon, and the paratele diezeugmenon, are reported to coincide. Nor do the eighteen choroi seem perfectly distinct in any of the other genera, except in the ephoronic. Wallis's Appendix ad Prohem. Harp. p. 158. See ENHARMONIC and SCALE.

DIAGRYDIUM, in Pharmacy, is scammony prepared, or corrected, for medicinal use.

The preparation is ordinarily performed by baking the scammony in a quince. Others make it to receive the fumes of lighted sulphur, whence it is called, *sulphureatus*, or *diagramma sulphureum*. Some incorporate it with a quantity of spirit of vitrol rotatum, sufficient to make a sort of liquid pills, which is afterwards set to dry in the sun, or by a gentle fire: and this preparation they call *diagramma vitreum*. The end of all these preparations is to correct the scammony; but the generality of authors now are of opinion, it has nothing that needs correction, and that it may be used in its natural state.

DIAM, or **DIARY**, a name given by the Arabs to the punishment of retaliation. By the Mahometan law, a brother, or the next relation of a murdered person, ought to take part against the murderer, and demand his blood in reparation for that which he has shed. Before the time of Mahomet, the Arabs had a custom of putting a freeman of their prisoners to death, in lieu of every slave they took in battle, and a man for every woman that was killed. But Mahomet regulated the laws of reprisal; directing in the Alcoran, by the *diam*, that a freeman should be required for a freeman, and a slave for a slave. The Turks, probably in consequence of this law, formerly massacred almost all their prisoners of war, but they now content themselves with enslaving and selling them. Encyclop.

DIAPHANINA, from *dia* and *phanos*, *visibile*, among *Farriers*, a drink made for horses, denominated from the six ingredients it consists of; viz. birthwort, gentian-root, juniper-berries, bay-berries, myrrh, and ivory-shavings. It is esteemed a good stomachic, and cures bites of venomous beasts, colds, consumptions, &c.

DIAION, in the ancient *Writers of Medicine*, the name of a composition made into the form of toches, of which violet flowers were one of the principal ingredients. The composition is described at large by Nymphis.

DIAL, or **SES-DIAL**, an instrument serving to measure time, by means of the shadow of the sun.

The word is formed from *di*, because indicating the hour of the day. See *HOR.*

The ancients also call it *guthierium*, from its doing it by the shadow.

DIAL is more accurately defined, a draught, or description, of certain lines on a plane, or surface, of a body given, to contrived, so that the shadow of a style, or ray, of the sun, passed through a hole therein, shall touch certain points at certain hours.

The antiquity of *dials* is beyond doubt. Some attribute their invention to Anaximenes Milesius; and others to Thales. Vitruvius mentions one made by the ancient Chaldee-billousus Berofus, on a reclining plane, alioest parallel to the equinoctial. Aristarchus Samius invented the hemispherical *dial*. And there were at the same time some spherical ones, with a needle for a gnomon. The office of Aristarchus was an horizontal *dial*, with its limb raised up all around, to prevent the shadow stretching too far.

But it was late before the Romans became acquainted with *dials*. The first *fun-dial* at Rome was set up by Papius Carus, about the year of the city 460, before which time, says Pliny, there is no mention of any account of time but by the sun's rising and setting: the first *dial* was set up at or near the temple of Quirinus, but it went ill: about thirty years after, M. Valerius Messala being consul, brought out of Sicily another *dial*, which he set up on a pillar near the rostrum; but for want of its being made for that latitude, it could not go true. They made use of it ninety-nine years; till Marcius Philippus set up another more exact.

But there seem to have been *dials* among the Jews much earlier than any of these. Witness the *dial* of Ahaz, who began to reign four hundred years before Alexander, and within twelve years of the building of Rome; mentioned by Isaiah, chap. xlviii. ver. 8.

The diversity of *fun-dials* arises from the different situation of the planes, and the different figure of the surfaces whereon they are described; whence they become denominated *equinoctial*, *horizontal*, *vertical*, *polar*, *declivity*, *inclivity*, *reclivity*, *retroclivity*, *cylindrical*, &c. For the general principles of their construction, see **DIALING**.

Dials are sometimes distinguished into *primary*, and *secondary*.

DIALS, *primary*, are those either drawn on the plane of the horizon, called *horizontal dials*; or, perpendicular thereto, on the planes either of the meridian, or prime vertical, called *vertical dials*: to which number are also usually added, those drawn on the polar and equinoctial planes, though neither *horizontal*, nor *vertical*.

DIAL, *equinoctial*, is that denoted on an equinoctial plane, or a plane representing that of the equinoctial.

A plane oblique to the horizon, either hangs over towards it, and makes an acute angle with the plane of the horizon, or it falls off backwards from it, and makes an obtuse angle therewith. The latter is called a *reclivity plane*, which, if it recline back at an angle equal to the complement of the latitude of the place, then it lies in the plane of the equinoctial; and a *dial* drawn thereon, is denominated an *equinoctial dial*.

Equinoctial dials are usually distinguished into *upper*, which looks towards the zenith; and *lower*, which respects the nadir.

Now, as the sun only illumines the upper surface of an equinoctial plane, while he is in our hemisphere, or on the northern side of the equator, an *upper equinoctial dial* will only shew the hour, during the spring and summer season.

And again, as the sun only illumines the lower surface of an equinoctial plane, while he is in the southern hemisphere, or on the other side of the equator, a *lower equinoctial dial* will only shew the hour in autumn and winter. To have an *equinoctial dial*, therefore, that shall serve all the year round, the *upper* and *lower* must be joined together; that is, it must be drawn on each side of the plane.

And, since the sun shines on one side or on the other of an equinoctial plane the whole day, such a *dial* will shew all the hours of an artificial day.

To describe an equinoctial Dial geometrically.—The *equinoctial* is the first, easiest, and most natural, of all *dials*; but the necessity of drawing it double, prevents it being much in use. However, as its structure shews the reason of the other kinds, and as it even furnishes a good mechanical method of drawing all the other kinds of *dials*, it shall be here laid down.

First, then, to describe an *upper equinoctial dial*: from a centre C (*Tab. Dialing*, fig. 4.) describe a circle ABDE, and by two diameters AD, and BE, intersecting each other at right angles, divide it into quadrants AB, BD, DE, and EA. Subdivide each quadrant into six equal parts, by the right lines C I, C H, C M, &c. which lines will be hour-lines. Through the centre C draw a style, or pin, perpendicular to the plane ABDE.

The *dial* thus described being raised so as to be in the plane of the equator, the line C XII, in the plane of the meridian, and the point A looking towards the south, the shadow of the style will shew the hours both of the forenoon and afternoon.

For horary circles include arches of the equator of fifteen degrees each; consequently, the plane ABDE being supposed in the plane of the equator, the horary circles will likewise include arches of 15 degrees of the circle ABDE. Wherefore, since the angles XII C XI, XI C X, X C IX, &c. are each here supposed 15 degrees, the lines C XII, C XI, C X, C IX, &c. are intersections of horary circles with the plane of the equinoctial. Again, since the style passing through the centre C represents the axis of the world; its distance from the centre of the earth being inconsiderable, and it being the common diameter of the horary circles, its shadow will cover the hour-line C XII, when the sun is in the meridian, or circle of 12 o'clock; C XI, when in the circle of 11 o'clock; C X, when in the circle of 10 o'clock, &c.

Secondly, to describe a *lower equinoctial dial*: the method is the same as that for the *upper dial*, already described; except that no hour-lines are to be drawn beyond that of 6 o'clock.

Thirdly, to describe an *universal equinoctial dial*: join two metal, or ivory planes, ABCD, and CDEF (*fig. 5*), so as to be movable at the joint. On the upper surface of the plane ABCD, describe an *upper equinoctial dial*, and upon the lower a *lower*, as already directed; and through the centre C draw a style. In the plane CDEF set a box, and put a magnetical needle G therein, so on the same plane a brass quadrant nicely graduated, and passing through a hole cut in the plane ABCD. Now, since this may be so placed, by means of the magnet, that the line G 12 shall be in the plane of the meridian; and, by means of the quadrant, may be so raised, that the angle BCF shall be equal to the elevation of the equator; it will serve as a *dial* in any part of the world. When the sun is in the equator, these *dials* can be of no use.

The best universal *dial* is that of Mr. Parille, of which the following description is given by Mr. Ferguson: This

dial consists of three principal parts: the first is called the horizontal plane A (fig. 6) because in practice it must be parallel to the horizon; in this plane is fixed an upright rim, which enters into the edge of the second part BD, called the meridional plane, which is made of two pieces, the lower whereof, D, is called the quadrant, because it contains a quarter of a circle divided into 90 degrees, in which part, near B, the sun enters. The other piece is a femicircle D, adjusted to the quadrant, and turning in it by a process for ruling or describing the diameter EF of the femicircle, which diameter is called the axis of the instrument. The third piece is a circle G, divided on both sides into twenty-four equal parts, which are the hours. This circle is put on the meridional plane, so that the axis EF may be perpendicular to the circle, and the point C be the common centre of the circle, femicircle, and quadrant. The straight edge of the femicircle is chamfered on both sides to a sharp edge, which passes through the centre of the circle. On one side of the chamfered part, the next six months of the year are laid down, according to the sun's declination for their respective days, and on the other side the last six months. And against the days on which the sun enters the signs, there are straight lines drawn upon the femicircle, with the characters of the signs marked upon them. There is a black line drawn along the middle of the upright edge of the quadrant, over which hangs a thread H, with its plummet I, for rectifying the instrument. From the 21st of September to the 21st of March, the upper surface of the circle must touch both the centre C of the femicircle, and the line of 90° and 0° , and from the 21st of March to the 23rd of September, the lower surface of the circle must touch the centre and line. In order to find the time of the day by this *dial*, it must be taken a level place in a sun-shine, and adjusted by the leveling screws α and β , till the plummet hangs over the black line upon the edge of the quadrant, and parallel to the said edge; then move the femicircle in the quadrant, till the line of 90° and 0° (where the axis touches) comes to the latitude of the place in the quadrant, and turn the whole meridional plane BD, with its circle G, upon the horizontal plane A, till the edge of the diameter of the circle falls exactly on the day of the month in the femicircle; and then the meridional plane will be due north and south, the axis EF will be parallel to the axis of the world, and will cast a shadow upon the true time of the day, among the hours on the circle, which is now in the plane of the meridional. The upper surface of the circle will serve from the 21st of March to the 23rd of September; and the lower for the rest of the year.

The months and signs are laid down on the femicircle in the following method. Draw the right line ACB (fig. 7) equal to the diameter of the femicircle ADB, and erect it in the middle at right angles with the line ECD, equal in length to ADB; then EC will be the radius of the circle FCC, which is the same as that of the femicircle. Upon E, as a centre, describe the circle FCC, on which let all the arcs C α and C β , each equal to $33\frac{1}{2}$ degrees, and graduate them accordingly, for the sun's declination. Then, laying the edge of a ruler over the centre E, and also over the sun's declination for every fifth day of each month, as found in tables of declination, mark the points on the diameter AB of the femicircle from α to β , which are cut by the ruler; and here place the days of the month, answering to the sun's declination. Set one foot of the compasses in C, and extending the other to α or β , describe the femicircle $\alpha\beta$ of 90° divide this into six equal parts, and through the points of division draw right lines parallel to CD, for the beginning of the sun (of which one half are on one side of the femicircle, and the other half on the other) and let the characters of the signs to their proper lines. Ferguson's Lectures, &c. Lect. 10.

DIAL, horizontal, is that described on an horizontal plane, or a plane parallel to the horizon.

Since the sun only illumines an horizontal plane at all times of the year, while he is above the horizon, an *horizontal dial* may then tell all the hours of the artificial day throughout the year; so that a more perfect *dial* than this kind cannot be required.

To describe an horizontal DIAL rectifiably. Draw a meridional line AB (fig. 8) on the given immovable plane; and place it, at pleasure, on a movable one. See Meridian line.

From a point centre at pleasure, in C, erect a perpendicular CD, and make the angle CAD equal to the elevation of the pole. In D make another angle CDE, equal likewise to the elevation of the pole, and draw the right line DE meeting AB in E. Then make EB equal to ED, and from the centre B, with the radius EB, describe a quadrant EBF, which divide into six equal parts. Through E draw the right line GH, cut-

ting AB at right angles. From the centre B, through the several subdivisions of the quadrant EF, draw right lines Ba, B β , B γ , B δ , BH, meeting the line GH, in the points α , β , γ , δ , H. From E upon the right line EG set off the intervals Ea, E β , &c. viz. Ea from E to α , E β from E to β , &c. From E to γ , &c. From the centre A, describe a little circle, and applying a little ruler to A, and the finite points of division α , β , γ , δ , H, and α , β , γ , δ , G, draw the lines AX, A β , A γ , A δ , A VII, A VII, and A α , A II, A III, A IV, A V. Through A draw a right line VI, perpendicular to AB. Continue the right line A VII, beyond the little circle, in VII, A VIII to VIII, A V to V, and A IV to IV. Round the whole figure draw a square, circle, or oval figure. And let it be in A its number, making an angle DAC with the meridian AB, equal to the elevation of the pole, or α of C erect a perpendicular line equal to CD, or α of A, in a triangular plane AD, perpendicular to the plane of the *dial*. In this case, the lines A XI, A N, A IX, &c. measure the hour lines of the femicircle, and A I, A II, A III, &c. those of the quadrant; and the shadow of any of the gnomons, or styles, above mentioned, at the several hours, will fall on the respective hour-lines.

To describe an horizontal DIAL rectifiably, in large dial, where the non-circularity is required, concentric lines are left for style, and in lieu thereof, the lines of the l are to be determined by trigonometrical calculation. Mr. Clavius, in the *Methodus de Elementis*, Regius des Nombres, anno 1707, has done the world good service herein; having rendered the calculation of the hour-lines, which before had been tedious enough, exceedingly easy and expeditious: his canon, or *table*, may well lay down under the respective kinds of *dials*. And, first, for an *horizontal dial*, the elevation of the pole of the place being given, to find the angles, which the hour-lines make with the meridian in the centre of the *dial*.

The analogy, or canon, is thus: as the whole line is to the sine of the elevation of the pole of the place, so is the tangent of the sun's distance from the meridian, for the hour required, to the tangent of the angle required: that is, as the side AC (fig. 9) is to DC, so is the tangent of FDC to the tangent FC, of the angle FDC. See TABLE 7, &c.

To describe an horizontal DIAL by the terrestrial globe. Let a common globe of twelve inches diameter, upon which six straight lines (twenty-four meridians femicircles) be elevated to the latitude of any given place, and placed about each any one of their meridians, raise the horizon in the north point, where the hour of XII is supposed to be marked; the arcs of the meridians will cut the horizon at the respective distances of all the other hours from XII. Let their points of distance be marked on the horizon, the globe be removed, and a flat board or plate, even with the surface of the horizon, put into its place: then straight lines drawn from the centre of the board to these points will be the hour lines of an *horizontal dial* for that latitude; and the gnomon will be in the situation of the axis of the globe, or make an angle with the plane of the *dial* equal to the latitude of the place. If the globe be elevated to the complement of the latitude of the given place, and you proceed as above, you will have a *dial* from which observing, that the gnomon makes an angle with the *dial* plane equal to the co-latitude of the place, and that the hours on the *dial* will be for the contrary way to that on the horizontal. If the globe has more than twenty-four meridians femicircles, the process is somewhat different. Elevate the pole to the latitude $51^\circ 42'$ N. e. g. of London, and bring the first meridian, in that of London on the English globe, to the north; let the hour index to the uppermost XII on the board circle; then turn the globe westward, till the index points successively to I, II, III, IV, V, and VI, in the atmosphere of the globe, and the hour lines will be the meridian of twelve o'clock line on the *dial*. At right angles to this meridian, draw g and o , and a and α , as centres, with the same radius of any length, describe the quadrants g and o , and a and α , and graduate them. The centre of the plane C, and the centres of these quadrants a and α , are at a little distance from each other, in order to enlarge the hour distances about noon. Lay a ruler on the centre α , and on the several divisions already found, viz. 11 $\frac{1}{2}$, 24 $\frac{1}{2}$, &c. in the quadrant g , and draw the respective afternoon hour lines to I, II, &c.

860. As the sun rises about four in the morning, on the longest days in London, continue the hour lines of III and V in the afternoon through the centre d to the opposite side of the dial. Then lay the ruler on the centre d through the same distances, respectively in the quadrant xy , draw the forenoon hour-lines of XI, X, &c., and as the sun does not set before eight in the evening on the longest days, continue the hour lines of VII and VIII through the centre d to the other side. Through 51° degrees of either quadrant from the centre draw the right line ac , which will be the hypotenuse of the gnomon cd , and from d fall a perpendicular to the meridian xy , and you will have the hypotenuse cd set up between d and c will have an hypotenuse cd parallel to the axis of the world, when the dial is truly set, and will cast a shadow on the face of the dial. A line of chords will furnish the degrees of projecting the gnomon. An *erec dial* (Fig. II, p. 15) is constructed in the same manner, observing the rule already given with respect to the elevation of the pole, and of the gnomon, and the position of the hours. Ferguson's dial is Fig. 10.

To draw an horizontal Dial, method 1st, in the style 1st style. Draw a double meridian line cd , (Fig. 11) on the horizontal plane, and erect it as a right angle by the line cd clock line xy , and the latitude of the place with the compass, in the scale of latitudes, and for that extent from d to c , and from d to e , on the six o'clock line; then, taking the whole six hours between the points of the compass in the scale of hours, with that extent (or one foot in the point c , and for the other foot fall where it will upon the meridian line cd , and at d . Do the same from d to e , and draw the right lines cd and de , each of which will be equal in length to the whole scale of hours. When this is done, let one foot of the compass be the beginning of the scale at XII, and extending the other to each hour on the scale, lay off these extents from d to c for the afternoon hours, and from d to e for those of the forenoon, and then the lines cd and de will be divided in the same manner as the hour scale is divided, at 1, 2, 3, 4, 5, and 6; on which the quarters may also be laid down, if required. Then, laying a ruler on the point d , draw the first five hours in the afternoon from that point through the dots at the several figures 1, 2, 3, 4, 5, on the line cd , and continue the lines of III and V through the centre d on the other side of the dial, for the first hours of the morning; then lay the ruler on the point d , and draw the last five hours in the forenoon through the dots 1, 2, 3, 4, 5, on the line de , and continue the lines of VII and VIII through the centre d to the other side, for the last hours of the evening; and the gnomon is in the respective lines, and make the gnomon in the manner already directed for the *horizontal dial*.

An *erec dial* may be made, by taking the co-latitude of the place from the scale of latitudes, and proceeding in all respects for the hour-lines, as in the *horizontal dial*, only reversing the hours, as in Fig. 15, and making the angle of the style's height equal to the co-latitude.

An *horizontal dial* may be easily designed with only a line of chords, of a graduated quadrant of a circle. With any opening of the compass, as ZL , (Fig. 12) describe the two semicircles LEF and LQF , on the centres Z and A , where the six o'clock hour line crosses the double meridian line, and divide each semicircle into twelve equal parts, beginning at L ; then connect the divisions, which are equidistant from L , by the parallel lines RM , IN , HO , GP , and FQ . Draw VZ equal to the latitude of the place, and continue the line VZ to R . Draw the line RV parallel to the six o'clock line, and for oil the distance K from Z to Y , the distance YI from Z to X , YI from Z to W , YG from Z to T , and YX from Z to S . Then draw the lines S, T, W, X, P , and Y, S , each parallel to R, V . Set off the distance Y from d to 1 , and from d to W from d to 9 , and from d to 10 from d to 6 , and from d to 7 , and from d to 5 . Then laying a ruler to the centre d , draw the forenoon hour-lines through the points $1, 2, 3, 4, 5$, and the afternoon lines through the points $1, 2, 3, 4, 5$, continuing the forenoon lines of VII and VIII through d to the opposite side of the dial, for the like afternoon hours; and the afternoon lines III and V through d for the like morning hours. Set the hours to the lines, and erect the style, and the dial is complete. A *port dial* may be constructed in the same manner, by drawing the line VZ to make an angle with the meridian ZL equal to the colatitude of the place, &c. reversing the hours, as in Fig. 15. Ferguson's dial supra.

DIAL, *method*, is that drawn on the plane of a vertical circle. See VERTICAL.

Of these there are several varieties, according to the vertical pitched upon. The verticals chiefly used are the prime vertical, and the meridian, from which respectively arise, *South, North, East, and West* dial.

Dial, which respect the cardinal points of the horizon, are particularly called *direct dials*. See DIRECT.

If any other vertical be chosen, the dial is said to decline. Further, if the circle, whose plane is used, be perpendicular to the horizon, as is supposed by the case in all these now mentioned, the dial is particularly denominated *style*. E. g. *style South, style North*, &c.

Otherwise, the plane being oblique to the horizon, they are said either to *decline, or to recline*.

DIAL, *method*, more particularly, an *erec dial* (Fig. 13) is that described on the surface of the prime vertical circle looking towards the south.

Since the sun then illumines the plane of the prime vertical looking to the south, when, in its progress, he passes from the prime vertical to the meridian, or returns back from this to that; in which he is employed six hours before, and six after noon, a *style* cd will show the hours from six in the morning to six at night.

DIAL, *is drawn a vertical plane*. On the plane of the prime vertical looking towards south, draw a meridian line AB (Fig. 13), and taking the distance AC , or picture, for the magnitude of the latitude of the place, describe a circular arc, of an indefinite length CD , with the centre C , and the radius CA equal to the elevation of the sun at noon, draw the right line AD , meeting the perpendicular CD at D .

Then in the prime D make the angle EDF equal to the elevation of the sun at noon, and draw the right line DE cutting the meridian in E . Through E draw the right line GH , cutting the meridian AB at right angles. Take E as equal to HD , and with this radius describe a quadrant EKF . The rest is performed as in an *horizontal dial*, except that the hours of the afternoon 3 to 6 be written on the right hand, and those of the forenoon on the left; as may be collected from the figure. Lastly, in the point A fix an indefinite style, in an angle equal to the elevation of the equator, or in C erect a perpendicular style, equal to CD , or, lastly, a triangular plate ADL , upon AD , so as to be perpendicular to the plane of the dial.

Then will the shadow of any of these indexes teach the several hour-lines at their respective hours.

DIAL, *style, unequal direct style* (Fig. 14) is that described on the surface of the prime vertical looking northward.

Since the sun only illumines this latitude while he passes from the south to the prime vertical, and proceeds from the same vertical to the south, and then he is in the tropic north at six o'clock in the morning, and at six in the evening; a *style* cd will show the hours before six in the morning, and those after six in the evening. And hence, as in autumn and winter-time, the sun does not rise before six, and set before six in the evening, a *method* of no use at that time, but that time paired with a *style* cd supplies the defect directed.

DIAL, *is drawn a vertical north*. Draw a circular line EB , (Fig. 14) and from A describe a little circle as picture. At A make the angle DAC equal to the elevation of the equator, and from the point C , taken as picture, draw a perpendicular CD , meeting AD in D . Make another angle CDE , EDC , equal to the elevation of the equator, and draw a line DE , meeting AD in E ; then take EB equal to ED , and through E draw GH , cutting AB at right angles; and from the centre B , with the radius BE , describe a quadrant, which divide into six equal parts through the two extreme divisions draw lines from the centre B , viz. BA , and BG , meeting GH in I and G , and make LI equal to LE , and LI equal to IG ; then applying a ruler to A and 6 , and A , and again to A and 2 , and A , draw the right lines A, V , and A, W , and A, VI . Lastly, at A fix an oblique index A, D , making an angle DAL with a meridian line in the plane of the meridian, equal to the elevation of the equator; or a perpendicular index in C , equal to CD ; or, instead of an index, a triangular plate A, D, L , on the meridian line EA , perpendicular to the plane of the dial.

Then will A, V , A, W , and A, VI , the indexes of the forenoon, and A, VI , A, VII , and $A, VIII$, those of the afternoon, and, accordingly, will be pointed out when the sun is in the several indexes. Or draw a *style* cd , as in the *horizontal dial*, beyond the line VI and VI , and the triangle ADL about its pole A , till AK fall directly on the line VI ; it is evident, a *style* cd is better than an index, for what has been said about writing.

To draw a *vertical style* or *port dial* (Fig. 15) is that which differs from the *horizontal dial*, in that the angle CAL is equal to the complement of the elevation of the pole of the place; so that the time analogy serves as for the horizontal one; only making the second time the complement

• complement of the elevation of the pole of the place. For the method of describing this *dial* by a globe, and by *Diagrams*, *see* *Horizontal Dial*.

DIAL, *rect*, or *rect* *rect* *rect* *DIAL*, is that drawn on the plane of the meridian, looking to the east. Since the sun always illuminates the plane of the meridian looking eastward, before noon, *an upper dial* can only show the hours till twelve o'clock.

DIAL, *to describe on rect*. On the eastern face of the plane of the meridian draw a right line A B, (see II. fig. 1st.) parallel to the horizon, and to this join A K, making with it an angle K A B, equal to the elevation of the equator, drawn with the radius D E, describe a circle, and with this centre D draw E C perpendicular to A B, by which means the circle will be divided into four quadrants. Each of these quadrants subdivide into four equal parts. And from the centre D through the several divisions draw the right lines D N, D V, D V I, D V I I, D V I I I, D I X, D X I. Lastly, in D erect a stile equal to the radius D E, perpendicular to the plane, or, on two little pieces perpendicularly fixed in B, and equal to the same radius D E, fix an iron rule parallel to E C. Thus will each index at the several hours project a shadow to the respective hour lines I V, V V, V I, V I, &c.

DIAL, *rect*, or *rect* *rect* *rect* *DIAL*, is that described on the western face of the meridian.

As the sun only illuminates that side of the plane of the meridian looking to the west, after noon, a *rect* *rect* *rect* *dial* can only show the hours from noon to night. This, therefore, joined with an *upper dial*, shows all hours of the day.

DIAL, *to draw a rect*. The construction is perfectly the same as that of an *upper dial*, only that its situation is inverted, and the hours are written accordingly.

DIAL, *pole*, is that described on a plane passing through the poles of the world, and the east and west points of the horizon. It is of two kinds; the first looking up towards the zenith, and called *upper*; the latter down to the nadir, called *lower*.

The *upper dial*, therefore, is inclined to the horizon to an angle equal to the elevation of the pole.

Since the *pole*, *pole*, P O Q S, (fig. 2d.) passes through the east and west points Q and S, a quadrant of the equator intersected between them and the meridian, consequently the upper face is illuminated by the sun from fix to the morning to fix at night; and the lower, from the nadir to fix in the morning, and from fix in the evening to fix at night. A *pole* *pole* *pole* *dial*, therefore, shows the hour of the morning from fix to fix at night, and that of the evening from fix to fix at night; and an *upper* *pole* *pole* *dial* from fix in the morning to fix in the evening.

DIAL, *to draw an upper pole*. Draw a right line A B, (fig. 3d.) parallel to the horizon; and if the plane be immovable, find the meridian line C E. Divide C E into two equal parts, and through C draw a right line E G parallel to A B. Then, from the centre D, with the interval D L, describe a quadrant, which divide into six equal parts; and from the same centre D, through the several points of division, draw right lines D I, D I I, D I I I, D I V, D V, &c. and the interval E I, E I I, E I I I, E I V, &c. on the contrary way, viz. E X I, X I, X I I, &c. and VII. From the points V, I V, I I I, I, &c. draw perpendiculars meeting the line E G in the corresponding points. Lastly, in D erect a perpendicular stile equal to D E, or, on two equal pieces, E and C, fix a cross iron rule. Then will X I, X I I, I, I I, I I I, &c. be hour-lines, to be pointed out at the proper notes by the shadow of the indices.

DIAL, *an upper pole*, only differs in situation, and the manner of writing the hours, from *upper* and *rect* *dials*, joined together in the line of fix at night.

DIAL, *a lower pole*, is that by passing out the hours of the forenoon, I X, X, and X I, and those of the afternoon, I, I I, and I I I, with the moonshine X I I I, and only leaving the hours VII and VIII of the morning, and IV and V in the evening.

To make three DIALS on three different planes, so that they may all show the time of the day in the summer. On the flat board A B C, (fig. 4d.) describe an horizontal *dial*, with its gnomon F G H, the edge of the shadow of which shows the time of the day. For this horizontal board join the upright board E D C, touching the edge G H of the gnomon; then making the top of the gnomon at G the centre of the vertical face, describe it on the board E D C. Besides, on a circular plate I K describe an equinoctial dial, and by a stile *see* in the XII. fig. 5d. line, from the edge to the centre, put it on the gnomon F G as far as the stile will admit. The same gnomon will show the same hour on each of those *dials*.

To draw all the primary DIALS on the same block of plate.

1. Let the plane A B C, (fig. 2d.) in the proper position of the block, be supposed horizontal; and thereon describe an horizontal *dial*. See *Horizontal Dial*.

2. Draw the right lines E M and F L parallel to D E; which, accordingly, in the proper position of the block, will be parallel to the horizon; then let the plane B N M C make an angle with E M, equal to the elevation of the pole C N E, and thereon describe an *upper pole dial*.

3. Let the opposite plane, A D E, make with E M an angle, D E M, equal to the elevation of the equator; and on this draw an *upper equinoctial dial*.

4. Let the plane, K L H I, make with F L an angle H L F, equal to the elevation of the equator; and on this describe a *lower equinoctial dial*.

5. Let the opposite plane, F G, make with F L an angle G F L, equal to the elevation of the pole; and here draw a *lower pole dial*.

6. Let the plane M N K L, and the opposite one, E F, be perpendicular to F L; and on this draw a *rect dial*, and on this a *rect dial*.

7. On the plane E M L F describe a *vertical dial*; and on the opposite plane A D E, a *rect dial*.

If, then, the block be so placed, as that the plane, M N K L, looks to the south, and the plane of the meridian, placed it in the line of 12 o'clock in the horizontal *dial* A B C D, and a *rect* *rect* *rect* *dial* M N E, in all the hours of the day will be indicated by several planes at once.

DIALS, *declining*, are all those drawn on the planes of other circles, besides the horizon, prime vertical, equinoctial, and polar circles; or those which either decline, incline, recline, or decline.

DIALS, *declining*, are erect or vertical *dials*, which decline from any of the cardinal points; or they are such as cut either the plane of the prime vertical, or of the horizon, at oblique angles.

The use of *declining dials* is very frequent, as the walls of houses, whereon *dials* are usually drawn, commonly deviate from the cardinal points.

Of *declining dials* there are several kinds, which are distinguished from the cardinal points, which they seem most to respect, but from which they have a real declination; *decliners* from the south, and from the north, and even from the zenith.

To draw a vertical declining Dial trigonometrically.

1. The declination of the plane, and the elevation of the pole of the place, being given, to find the angle formed in the centre of the *dial*, by the meridian and substile.

Canon. As the whole sine is to the tangent of the complement of the height of the pole of the place G F, (fig. 2d.) so is the sine of the angle of the declination of the plane G F D, to the tangent G D, at the angle required G A D.

2. The declination of the plane being given, and the elevation of the pole of the place, to find the angle formed in the centre of a vertical *declining dial*, by the substile and axis.

Canon. As the whole sine is to the sine of the complement of the elevation of the pole G F, so is the sine of the complement of the declination of the plane D G F, to the sine D F, the sine of the angle D A B required.

3. The declination of the plane, and the elevation of the pole, given, to find the difference of longitude, that is, the arch of the equator, comprehended between the meridian of the place and the meridian of the plane.

Canon. As the whole sine is to the sine of the height of the pole of the place, so is the tangent of the complement of the declination of the plane, to the tangent of the complement of the difference of longitude.

4. The angle of the difference of longitude, and that of the axis, with the substile, being given, to find the angles formed in the centre of a vertical *declining dial*, between the substile and hour-lines.

This problem admits of three cases, for the hour-lines, whose angles are sought, may be either, 1. Between the meridian and substile; or, 2. Beyond the substile; or, 3. On that side the meridian where the substile is not.

In the two first cases, the distance is to be taken between the sun's distance from the meridian, that hour, and the angle of the difference of longitude found by the 3d. problem; and in the third case, the sum of those two angles is to be taken, and the following canon used.

Canon. As the whole sine is to the sine of the angle between the axis and substile, so is the tangent of the difference of the sun's distance from the meridian, and the difference of longitude, or of the sum of those two angles, to the tangent of the angle required.

5. The angle formed by the substile, with the hour-lines, and that of the substile, with the meridian, given, to find the angles formed between the meridian and hour-lines in the centre of vertical *declining dials*.

1. The angles of the hour-lines between the meridian and substile are found by subtracting the angle formed by the substile with the hour-line, from the angle formed by the substile with the meridian.

2. The angles beyond the substile, and on the side opposite

Posite to that of the meridian; are found by adding those two angles.

3. Those on the other side the meridian are found by taking their difference.

To describe a vertical *DIAL*, declining from the south to the east or west, *geometrically*. Find the declination of the plane, as already taught, under the article *DIRECTIONATOR*. Then draw upon a paper an *horizontall dial*, supposing the line of contingency of the horizontal with the equinoctial plane to be GH (fig. 22), through the point E, wherein the meridian line AE cuts the same, draw a right line IK, making with GH an angle HEK, equal to the declination of the given plane. Thus, as GH represents the intersection of the prime vertical with the horizon, IK will be the intersection of the declining plane, and the horizon; whence we also conceive, that the part IE must be raised above GE, in case the given plane decline to the west; or it must be depressed below the line GE, in case it decline to the east. Draw a right line parallel to the horizon on the given plane, or wall, to answer to IK; and assuming a point therein answering to E, let a line from the right line IK on the paper the several hourly distances E 1, E 2, E 3, &c. Then from the point E erect a perpendicular EC, equal to the distance of the centre of the *horizontall dial*, from its line of contingency. Draw lines thence to the several points of the hour-lines E 1, E 2, E 3, &c. Let fall a perpendicular AD, from the centre of the *horizontall dial* A, to the line of contingency IK, and transfer the distance ED, from the point E, upon the wall; then will CD be the substylar line.

Wherefore joining AD and DC at right angles, the hypotenuse AC will be an oblique index, to be fastened on the wall in the point C, according to the angle DCA. To construct a vertical *DIAL*, declining from the south towards the east or west, by the globe. Elevate the pole to the latitude of the place, and direct the quadrant of altitude to the zenith. If the dial declines towards the south, count the degree of declination in the horizon from the east point towards the north, and bring the lower end of the quadrant to that degree of declination, at which the reckoning ends. Then bring the meridian, (i. e. the first meridian) directly under the graduated edge of the upper part of the brass meridian, and let the hour index to XII at noon. Turn the globe outward on its axis, the quadrant of altitude being kept to the degree of declination in the horizon, and observe the degrees cut by the first meridian in the quadrant of altitude, counted from the zenith, as the hour index comes to XI, X, IX, &c. in the forenoon; and the degree, then cut in the quadrant by the first meridian, in the respective distances of the forenoon hours from XII on the plane of the dial. For the afternoon hours, turn the quadrant of altitude round the zenith till it comes to the degree in the horizon opposite to that where it was placed before, or as far from the wall point towards the south, as it was at first from the east towards the north; and turn the globe outward on its axis, till the first meridian comes to the brass meridian, and the hour index to XII, then turning the globe westward to the afternoon hours I, II, III, &c. the first meridian will cut the quadrant of altitude in the respective number of degrees from the zenith, thus each of these hours is from XII on the dial, and the limit of this dial will be determined by the hour index, when the first meridian goes off the quadrant at the horizon, both in the forenoon and afternoon. Lay down these hour distances on the dial plane, either by dividing a semicircle into two quadrants, beginning at the hour line of XII, or by the line of chords, as directed under *Arithmetic* in art. 1. As the sun's ray makes an angle with the meridian line in this kind of dial, falling among the forenoon hour-lines in an east declining, and among those in the afternoon in a west declining towards the wall, its distance may be found in the former, by counting the degrees of the declination of the dial in the horizon from the east point towards the north, and bringing the lower end of the quadrant of altitude to that degree of declination, where the reckoning ends; then turn the globe till the first meridian cuts the horizon in the like number of degrees, counted from the fourth point toward the east; and the quadrant and first meridian will cross one another at right angles, and the number of degrees of the quadrant intercepted between the first meridian and the zenith, is equal to the distance of the substylar line from the 12 o'clock line; and the number of degrees of the first meridian, which are intercepted between the quadrant and the north pole, is equal to the elevation of the style above the plane of the dial. If the dial declines westward from the south, count that declination from the east point of the horizon towards the north, and bring the quadrant of altitude to the degree in the horizon at which the reckoning ends; both for finding the forenoon hours, and distance

of the substylar from the meridian; and for the afternoon hours bring the quadrant to the opposite degree in the horizon, as far from the wall towards the north; and then proceed as above. A north dial declining east or west by the same number of degrees may be easily had from the former, by only extending the hour-lines, style, and substylar, quite through the centre; for thus the fourth-east decliner will produce the north-west decliner, and the fourth-west decliner the north-east decliner. Perfection, lib. vi.

To draw a vertical *DIAL*, declining from the south towards the east and west. Take the declination of the plane, as already taught; then, as north dials are only south dials inverted, draw a vertical dial declining from the south, and invert it in such a manner, as that the centre C looks to the horizon, and the point E to the zenith; and the hours on the right hand set off towards the left, and contrariwise, emitting all hour-lines, which in such a plane cannot be shown.

For the practice, the best way is, after drawing a fourth decliner upon paper, to prick the several points thereof through with a pin; then applying the face of the paper to the wall, the back line thereof will show you all the points necessary for the north declining dial.

DIALS, *oblique*, are those drawn on planes inclined, but inclining, or leaning forward towards the south, or southward line of the horizon, in a right angle, or more, or less than the equinoctial plane.

Such an inclined plane may be conceived to have some part of the plane of the equinoctial towards the zenith, and the other depressed towards the nadir; and that to resolve upon a line drawn from the east to the west point of the horizon.

DIALS, *oblique*, are divided into 3. The inclination of the plane, as DC (fig. 23) being found by a declinator, as taught under *Arithmetic* in art. 1. If it fall between the equinoctial plane GE, and the vertical one GB, in such manner as that the angle of inclination DCE is greater than the elevation of the equator ECA, on the upper side draw a north dial, and on the lower a south dial, to an elevation of the equator, which is equal to the aggregate of the elevation of the equator of the given place, and the complement of the inclination to a quadrant.

2. If the inclined plane CF fall between the horizontal one CA, and the equinoctial CE, so as that the angle of inclination FCA, is less than the elevation of the equator ECA, describe an *horizontall dial* to an elevation of the pole, equal to the aggregate of the elevation of the pole of the given place, and the inclination of the plane. *DIALS*, thus inclined, are drawn after the same manner as *primary dials*, except that the index in the former case must be fitted under the angle ADC, and in the latter, under the angle DFC; and that the distance of the centre of the dial from the line of contingency, in the former case, is DC, and in the latter FC.

DIALS, *oblique*, are those sloping planes not erect, but reclined, or leaning backward from the zenith towards the north, in an angle greater or less from the polar plane. A reclined plane may be conceived by supposing one part of the polar plane (sited towards the zenith) and the other depressed towards the nadir, and thus resolving about a line drawn from east to west. To find the declination of a plane, *oblique*, or RECLINATION.

DIALS, *reclining*, are divided into 2. If the reclined plane HC fall between the vertical plane DC, and the polar plane IC, so as that the angle of reclination HCH is less than the distance of the pole from the zenith ECA, defer to two vertical *first and north dials* to an elevation of the equator, equal to the difference between the elevation of the equator of the given place, and the angle of reclination. 2. If the reclined plane, as KC, fall between the polar plane IC, and the horizontal one CA, so as that the angle of reclination HCH is greater than the distance of the pole from the zenith ECA, describe an *horizontall dial* thereon to an elevation of the pole, equal to the difference between the angle of reclination, and the elevation of the equator of the given place.

To draw inclining and reclining *DIALS* *geometrically*. The inclination and declination of the plane, and the elevation of the pole, being known, to find the angles made in the centre of an inclining or reclining dial, by the meridian and hour-lines.

Such dials is properly an *horizontall dial*, for the style is equal to the particular elevation of the pole on the plane of the dial. Its angles, therefore, are found by the same method as down for *horizontall dials*.

As to the elevation of the pole on the dial plane IC, thus found: the plane being inclining, either towards the zenith is greater than the elevation of the pole of the place, or less, or it is equal thereto. In the two first cases, for upper *first*, or lower *north dials*, the particular elevation of the pole on the plane is had by taking the difference between the elevation of the pole of the place, and the

inclination of the plane; and in the latter case, the dial is a *polar dial*, wherein the hour-lines will be parallel, by reason that the plane being placed on the axis of the world, neither of the poles can be represented thereon.

For upper north, and lower south dial. 1. If the inclination be greater than the complement of the elevation, the complement of the inclination must be added to the complement of the elevation. 2. If it be less, the inclination must be added to the elevation. 3. If it be equal, the dial will be an *equinoctial dial*, wherein the angles at the centre will be equal to the sun's distance from the meridian.

Dials, distinguished, are those which both *decline* and *incline*, or *recline*. See **DECLINATIONS**.

The use of *inclined, reclined*, and especially *declined dial*, is very rare, the geometrical and trigonometrical construction of these last, therefore, as being somewhat intricate, we here choose to omit, and refer such as may have a fancy for such a dial, to an universal mechanical method of drawing all kinds of dials here subjoined.

A rule related to describe a Dial on any kind of plane, by means of an equinoctial Dial, or circle. Suppose, e. g. a dial required on an horizontal plane: if the plane be immovable as ABCD (Tab. II. fig. 24.) find a meridian line GF; or, if moveable, assume the meridian a pleasure. Then, by means of the triangle KEF, whose base is applied on the meridian line, raise the equinoctial dial H, till the base GI becomes parallel to the axis of the world (which is had, if the angle KEF be equal to the elevation of the pole), and the 12 o'clock line on the dial hang over the meridian line of the plane, or the base of the triangle. If then, in the night-time, a lighted candle be successively applied to the axis GI, so as the shadow of the index, or style GI, fall upon one hour-line after another, the same shadow will mark out the several hour-lines on the plane ABCD.

Noting the points, therefore, on the shadow, draw lines through them to G; then an index being fixed in G, according to the angle IGF, its shadow will point out the several hours by the light of the sun.

If a dial were required on a vertical plane, having raised the equinoctial circle, as above directed, push forward the index GI, till the tip thereof, I, touch the plane.

If the plane be *inclined to the horizon*, the elevation of the pole should be found on the same; and the angle of the triangle KEF should be made equal thereto.

See a new method of constructing *sun-dials* for any given latitude, without the assistance of dialling scales, or logarithmic calculations, by Mr. Ferguson, in the Phil. Trans. vol. lvi. for 1767. art. 36. and in his Select Exercises, p. 95.

Note, Beside the several species of dials above mentioned, which are said to be *with centres*, there are others called *dials without centres*. See **CENTRE of a Dial**.

Dials without centres, are those whose hour-lines do really converge, but so slowly, that the centre towards which they converge cannot be expressed on the given plane.

Dials, horizontal, without centres, are to be made for places, the elevation of whose pole is either very small, or very great.

Dials, vertical, without centres, are for places, the elevation of whose pole is very great.

Dials, for the furniture of. See **FURNITURE**.

Dial, quadrantal. See **Horodistical Quadrant**.

Dial, reflecting. See **Reflecting Dial**.

Dial, quadrant, is represented in Tab. III. fig. 27. This dial may be delineated on paper, and then pasted round a cylinder of wood, and it will shew the time of the day, the sun's place in the ecliptic, and his altitude at any time of observation. Draw the right line AB (fig. 28.) parallel to the top of the paper, and with any opening of the compass on the centre A describe the quadrant AE, and graduate it. Draw the right line AC at right angles to AB, and touching the quadrant AE at the point A. From the centre A draw right lines through as many degrees of the quadrant as are equal to the sun's altitude at noon, on the longest day of the year, at the place for which the dial is to serve; which altitude at London is nearly 62 degrees; continue these right lines till they meet the tangent line AC; and from the points of concurrence, draw straight lines across the paper, parallel to the first right line AB, and these will be the parallels of the sun's altitude in whole degrees, from sun-rise to sun-set, on all the days of the year. These parallels of altitude must be drawn out to the right line BD, which must be parallel to AC, and as far from it as is equal to the intended circumference of the cylinder on which the paper is to be pasted. Divide the fence between the right lines AC and BD, at top and bottom, into twelve equal parts, for the twelve signs of the ecliptic; and from one mark to the opposite one, draw right lines parallel to AC and BD; and place the characters of the

twelve signs in the twelve spaces, at the bottom, beginning with γ Cancer, and ending with χ Pisces. These spaces should likewise be divided by parallel lines into halves and quarters. At the top of the dial make a scale of the months and days of the year, so that the days may stand over the sun's place, found in an Ephemeris, for each of them in the signs of the ecliptic. Compute the sun's altitude for every hour, in the latitude of your place, or take it from a table, such as that subjoined, when he is in the beginning, middle, and end of each sign of the ecliptic; and in the upright parallel lines, at the beginning and middle of each sign, make marks for these altitudes among the horizontal parallels, reckoning downward in the order of the numeral figures at the right hand, answering to the like divisions of the quadrant at the left. Through these marks draw the curve hour-lines, and let the hours to them, as in the figure, reckoning the forenoon hours downward, and the afternoon hours upward. The sun's altitude may also be taken and laid down for the half hours and quarters. Then cut off the paper at the left hand, on which the quadrant was drawn, close by the right line AC, and all the paper at the right hand close by the right line BD, and cut it also close by the top and bottom horizontal lines, and it will be fit for pasting round the cylinder. This cylinder, (fig. 27.) is hollow for holding the style DE, when it is not used. The style must stand out, perpendicular to the side of the cylinder, just over the right line AB (fig. 28.) where the parallels of altitude begin, and its length, or distance of the point E from the cylinder must be equal to the radius A of the quadrant AE (fig. 28.) When this dial is used, the horizontal foot BC is placed on a level table, or hung by the ring F, where the sun shines, and the horizontal top AD, which is made moveable, is turned till the style stands just over the day of the month. Then the cylinder is turned round, till the shadow of the style falls upon it, parallel to the upright lines which divide the signs; or till the shadow is parallel to a supposed axis in the middle of the cylinder and then the point E, or lowest end of the shadow, will fall upon the time of the day, as it is before or after noon, among the curve hour-lines, and will shew the sun's altitude at that time among the cross parallels of altitude, encompassing round the cylinder; and it will also shew in what sign of the ecliptic the sun is at that time, and the degree may be easily estimated by the eye. Ferguson.

A TABLE shewing what altitude the sun shall have at every hour, half, and quarter of the day, at his entrance into every one of the twelve Signs.

Calculated for the latitude of London, 51 deg. 33 min.

When the sun is in the equinoctial, and has no declination, his altitude may be easily found by the following proportion. As radius is to the cosine of the latitude, so is the cosine of the hour from noon to the sine of the altitude: but if he has north or south declination, say, as radius is to the sine of the declination, so is the sine of the latitude to the sine of the sun's altitude at six o'clock. For the sun's altitude at other hours the two following proportions must be used, viz. 1. As the cosine of the hour from the meridian to radius, so is the tangent of the latitude to the tangent of a fourth arc, from which the declination is to be subtracted, when north, and to which it is to be added, when south, for a fifth arc. The supplement of the sun's declination, added to the fourth arc, must be used for this fifth arc, when they exceed a quadrant, in finding the altitudes before and after six.

2. As the sine of the fourth arc is to the cosine of the fifth arc, so is the sine of the latitude of the place to the sine of the altitude for the given hour and declination.

The altitude in the middle of a sign may either be had by taking the arithmetic mean between the next greatest, and least, or by computation, in the manner above directed. Leybourn's Dialling, Tract vi. p. 23. &c.

To find the altitude by the globe, see GLOBE.

DIAL, portable, in a card, is represented in fig. 29. and may be easily constructed. Draw the occult line AB (fig. 30.) parallel to the top of the card, and cross it at right angles with the six o'clock line ECD; then upon C, as a centre, with the radius CA, describe the semicircle AEL, and divide it into twelve equal parts, beginning at A, as Ar, A₁, A₂, &c. and from these points of division draw the hour-lines r, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, all parallel to the six o'clock line EC. If each part of the semicircle be subdivided into four equal parts, they will give the half-hour lines and quarters, as in fig. 30. Draw the right line ASD, making the angle SAB equal to the latitude of the place. Upon the centre A, describe the arc RST, and let off upon it the arcs SR and ST, each equal to 23½ degrees, for the sun's greatest declination, and divide them into 23½ equal parts, as in fig. 29. Through the intersection D of the lines ECD and AD, draw the right line FDG at right angles to AD. Lay a ruler to the points A and R, and draw the line ARF through 23½ degrees of south declination in the arc SR, and then laying the ruler to the points A and T, draw the line ATG through 23½ degrees of north declination in the arc ST, so shall the lines ARF and ATG cut the line FDG in the proper length for the scale of months. Upon the centre D, with the radius DF, describe the semicircle FEG, which divide into six equal parts Fm, mn, ns, &c. and from these points of division draw the right lines mh, nh, ph, & q, each parallel to AD. Then setting one foot of the compass in the point F, extend the other to A, and describe the arc ASH for the tropic of æq; with the same extent, setting one foot in G, describe the arc AEO for the tropic of æq. Next setting one foot in the point S, and extending the other to A, describe the arc ACI for the beginnings of the signs æ and ♈; and with the same extent, setting one foot in the point E, describe the arc AN for the beginnings of the signs ♈ and ♈. Set one foot in the point I, and having extended the other to A, describe the arc AK for the beginnings of the signs ♈ and ♈. And with the same extent set one foot in A, and describe the arc AM for the beginnings of the signs ♈ and ♈. Then setting one foot in the point D, and extending the other to A, describe the curve AL for the beginnings of ♈ and ♈, and the signs will be finished. This done, lay a ruler from the point A over the sun's DECLINATION in the arc RST, found by a table, for every fifth day of the year; and where the ruler cuts the line FDG, make marks, and place the days of the months right against these marks, as in fig. 29. Lastly, draw the shadow line PQ parallel to the occult line AB: make the gnomon, and set the hours to their respective lines, as in fig. 29, and the dial will be finished.

The lines ad, ah, and be, of the gnomon, must be cut quite through the card; and as the end ad of the gnomon is raised occasionally above the plane of the dial, it turns upon the uncut line cd as on a hinge. The dotted line AB must be slit quite through the card, and the thread C must be put through the slit, and have a knot tied behind, to keep it from being easily drawn out. On the other end of this thread is a small plummet D, and on the middle of it a small bead for shewing the hour of the day.

To rectify this dial, set the thread in the slit right against the day of the month, and stretch the thread from

the day of the month over the angular point, where the curve lines meet at XII; then shift the bead to that point on the thread, and the dial will be rectified.

To find the hour of the day, raise the gnomon, and hold the edge of the dial next the gnomon towards the sun, so that the uppermost edge of the shadow of the gnomon may just cover the shadow line; and the bead then playing freely on the face of the dial, by the weight of the plummet, will shew the time of the day among the hour-lines, in the forenoon or afternoon.

To find the time of sun-rising and setting, move the thread among the hour-lines, until it either covers some one of them, or lies parallel betwixt any two; and then it will cut the time of sun-rising among the forenoon hours, and of sun setting among the afternoon hours for that day of the year to which the thread is set in the scale of months.

To find the sun's declination, stretch the thread from the day of the month over the angular point at XII, and it will cut the sun's declination, as it is north or south, for that day, in the proper scale.

To find on what day the sun enters the signs: when the bead, as above rectified, moves along any of the curve lines which have the signs of the zodiac marked upon them, the sun enters those signs on the days pointed out by the thread in the scale of months.

DIAL, universal, on a plain crescent, is represented by fig. 31. and is moveable on a joint C, for elevating it to any given latitude on the quadrant KGO, and for turning upon the horizontal board A. The arms of the crescent are at right angles to the middle part; and the top of it, from a to a, is of equal length with any of the arms ne or ns.

This dial is rectified, by setting the middle line to the latitude of the place on the quadrant, the board A level, and the point N northward by the needle; thus, the plane of the crescent will be parallel to the plane of the equator. Then from III o'clock in the morning till VI, the upper edge *hi* of the arm *ns* will cast a shadow on the time of the day on the side of the arm *em*; from VI till IX, the lower edge *el* of the arm *ns* will cast a shadow on the hours, on the side *es*. From IX in the morning to XII at noon, the edge *ed* of the top part *an* will cast a shadow on the hours on the arm *ne*; from XII to III in the afternoon, the edge *ed* of the top part will cast a shadow on the hours of the arm *hns*; from III to VI in the evening, the edge *eh* will cast a shadow on the hours on the part *ps*; and from VI till IX, the shadow of the edge *ef* will shew the time on the top part *an*. The breadth of each part *ah*, *ef*, &c. must be so great, as never to let the shadow fall quite without the part or arm on which the hours are marked, when the sun is at his greatest declination from the equator.

To determine the breadth of the sides of the arms which contain the hours, so as to be in just proportion to their length, make an angle ABC (fig. 32.) of 23½ degrees, which is equal to the sun's greatest declination; and suppose the length of each arm, from the side of the long middle part, and also the length of the top part above the arms, to be equal to B*d*. Then, as the edges of the shadow, from each of the arms, will be parallel to B*d*, making an angle of 23½ degrees with the side *hd* of the arm, when the sun's declination is 23½°, it is plain, that if the length of the arm be B*d*, the least breadth that it can have, to keep the edge B*e* of the shadow B*egd* from going off the side of the arm *ed*, before it comes to the end of it *ed*, must be equal to *ed* or *hd*. But, in order to keep the shadow within the quarter divisions of the hours, when it comes near the end of the arm, the breadth of it should be still greater, so as to be almost doubled, on account of the distance between the tips of the arms.

The hours may be placed on the arms, by laying down the crescent ABC (fig. 32.) on a sheet of paper; and with a black-lead pencil, held close to it, drawing its shape and size on the paper. Then take the length *ae* in the compass, and with one foot in the corner *a*, describe with the other the quadrant *ef*. Divide this arc into six equal parts, and through the points of division draw right lines *af*, *ah*, &c. continuing three of them to the arm *ce*, which are all that can fall upon it; and they will meet the arm in those points through which the lines that divide the hours from each other, as in fig. 32. are to be drawn right across it. Divide each arm into three hours contained in it, in the same manner, and set the hours to their proper places, on the side of the arms as they are marked in fig. 33. Each of the small spaces should be divided into four equal parts, for the half hours and quarters, in the quadrant *ef*; and right lines should be drawn through these division-marks in the quadrant, to the arms of the crescent, in order to determine

mine the places thereon, where the subdivisions of the hours must be marked.

This is a very simple kind of universal dial; it is easily made, and has a pretty uncommon appearance in a garden. Ferguson.

DIALS, refracting, are such as shew the hour by means of some refracting transparent fluid.

If a pin or stick be set up, or any point be assigned in a concave bowl or dish for the centre of the dial, let an horizontal dial be applied over the same, assigning the meridians line on the edges of the bowl, and marking out the rest of the hour-lines also on the edges of the bowl; take away the horizontal dial, and cleave a string or thread from the end of the said pin over the meridian line, as much as is the latitude or elevation of the pole of the place; then by bringing the thread to cast a shadow on any hour-point formerly marked out on the edges of the bowl, by a candle or the like, that shade in the bowl is the true hour-line; and if the bowl be full of water, &c. when this is done, it will never shew the true hour by the shadow of the top of the pin but when it is filled again with the same liquor.

DIAL, ring, is a kind of dial, usually small and portable, consisting of a brass ring or rim, seldom exceeding two inches in diameter, and one third of an inch in breadth. In a point of this rim there is a hole, through which the sun-beams being rectified, make a lucid speck on the convex side of the opposite femicircle, which gives the hour of the day in the divisions marked therein.

These divisions are made by describing a circle (Tab. IV. fig. 34.) to represent the ring, and drawing an horizontal chord E F, with this as radius describe the quadrant F D, and graduate it; and through the several degrees which mark the sun's altitude for every hour at the time of the equinox, draw lines from E to the opposite part of the circle, and there fix the corresponding figures. Thus the XII o'clock line will pass through $38^{\circ} 48'$, the co-latitude of the place; and the XI and I line through $36^{\circ} 56'$; the X and II through $35^{\circ} 36'$; the IX and III through $26^{\circ} 4'$; the VIII and IV through $18^{\circ} 8'$; and the VII and V through $9^{\circ} 17'$. This may be easily calculated by the globe; or see the preceding table.

But it only holds good about the times of the equinox. To have the dial perform throughout the whole year, the hole is made moveable, and the signs of the zodiac, or the days of the month, are marked on the convex side of the ring, by taking, e. g. E T and E I (fig. 34.) on each side of E equal to double the sun's declination when he enters any particular sign, as Taurus or Pices; and there marking the character of the said sign, or corresponding month, and so for all the others; and by means of these the dial is rectified for the time. It is evident, from a view of the figure, that E XII is = E F XII = the altitude of the sun in the equinox; but T XII is equal to the sun's declination in Taurus, because it is an angle in the circumference standing upon an arc, which is double the declination; and therefore T XII is equal to the meridian altitude when the sun enters Taurus; and a ray passing through the hole at T will mark the XII o'clock hour of that day; but this dial will not point out the other hours exactly; because T III is exceeds E III, the equinoctial hour by the angle of declination; and so of the rest. Some have contrived to remedy this inconvenience, by making the concave surface of the ring wider, and describing upon it seven circles, the middle one to represent the equinoctial, and the extremes the tropics; and in these circles they have marked the forenoon and afternoon hours from a table of altitudes.

To use it, put the moveable hole to the day of the month, or the degree of the zodiac the sun is in; then suspending it by the little ring, turn it towards the sun, till his rays, as before, point out the hour among the divisions on the inside.

Universal or astronomical Ring-DIAL, is a ring-dial which serves to find the hour of the day in any part of the earth, whereas the former is confined to a certain latitude. Its figure see represented in Tab. IV. of Dialling, fig. 35.

It consists of two rings or flat circles, from two to six inches in diameter, and their breadth, &c. proportionable. The outward ring A represents the meridian of any place you are at, and contains two divisions of 90° each, diametrically opposite to one another, serving the one from the equator to the north, the other to the south pole. The inner ring represents the equator, and turns exactly within the outer, by means of two pivots in each ring at the hour XII.

Across the two circles goes a thin replet or bridge, with a corrus C, that slides along the middle of the bridge. In the center is a little hole for the sun to shine through. The middle of this bridge is conceived as the axis of the world, and the extremities as the poles; and on the one

side are drawn the signs of the zodiac, and on the other the days of the month. On the edge of the meridian slides a piece, to which is fitted a ring to suspend the instrument by.

In this dial, the divisions on the axis are the tangents of the angles of the sun's declination, adapted to the semi-diameter of the equator as radius, and placed on either side of the centre: but instead of laying them down from a line of tangents, a scale of equal parts may be made, whereof 1000 should answer exactly to the length of the semi-axis, from the centre to the inside of the equinoctial ring; and then 434 of these parts may be laid down toward each end from the centre, which would limit all divisions on the axis, because 434 is the natural tangent of $23^{\circ} 29'$. And thus, by a motion fixed to the sliding-piece, and taking the sun's declination from an ephemeris, and the tangent of that declination from the table of natural tangents, the slider might be always set true within two minutes of a degree. And this scale of 434 equal parts might be placed right against the $23^{\circ} 29'$ of the sun's declination, on the axis, instead of the sun's place, which is there of little use. For then the slider might be set in the usual way, to the day of the month, for common use; but to the natural tangent of the declination, when great accuracy is required.

Use of the universal Ring-DIAL. Place the line A (on the middle of the sliding-piece) over the degree of latitude of the place (e. g. $51^{\circ} 14'$ for London) put the line which crosses the hole of the cursor to the degree of the hour, or day of the month. Open the instrument so as that the two rings be at right angles to each other, and suspend it by the ring H, that the axis of the dial, represented by the middle of the bridge, may be parallel to the axis of the world. Then turn the flat side of the bridge towards the sun, so that his rays striking through the little hole in the middle of the cursor, may fall exactly on a line drawn round the middle of the concave surface of the inner ring; in which case the bright spot shews the hour of the day in the said concave surface of the ring. Note, the hour of XII is not shewn by this dial, because the outer circle being then in the plane of the meridian, hinders the sun's rays from falling on the inner; nor will this dial shew the hour when the sun is in the equinoctial, because his rays then fall parallel to the plane of the inner circle.

Natural, or Night-DIAL, is that which shews the hours of the night.

Of this there are two kinds: *lunar* and *sidereal*.

Lunar-DIAL, or **Lunar-DIAL,** is that which shews the hour of the night by means of the light, or shadow, of the moon, projected thereon from an index.

To describe a Lunar-DIAL. Suppose, e. g. an horizontal meridian required: draw, first, an horizontal line, then erect two perpendiculars, A B and C D (Tab. II. fig. 25.) to the line of XII o'clock; and, dividing the interval G F into twelve equal parts, through the several points of division draw lines parallel thereto: now, approximating the first line C D to the day of the new moon, and the second to the day when the moon comes an hour later to the meridian than the sun; their intersections with the hour-lines will give points, through which to draw a curve line XII XII for the meridian-line of the moon. After the like manner determine the other hour-lines I I, II II, III III, &c. which the shadow of the moon, projected from the style of the dial, intersects at the respective hours; then blot out the hour-lines of the sun-dial, together with the perpendiculars whereby the lunar hours were drawn, and divide the interval G F, by other parallel lines, into fifteen equal parts, answering to the fifteen days between new and full moon; lastly, to these lines write the several days of the moon's age.

Now, the moon's age being learnt from a calendar, the intersection of the line of the moon's age with the lunar hour-lines, will give the hour of the night.

After the same manner may any other sun-dial be converted into a moon-dial.

To draw a portable Moon-DIAL. On a plane, that may be raised according to the elevation of the equator, describe a circle A B (fig. 26.) and divide its circumference into 202 equal parts; from the same centre C describe another moveable circle D E, which divide into twenty-four equal parts, or hours; in the centre C erect an index, as for an equinoctial dial.

This dial being duly placed, after the manner of an equinoctial dial, and the XII o'clock line brought to the day of the moon's age; the shadow of the index will give the hour.

To use a Solar or Lunar-DIAL, i. e. to find the hour of the night by a sun-dial. Observe the hour which the shadow of the index points at by moon-light; find the moon's age in the calendar, and multiply the number of days by 1, the product is the number of hours to be added to the hour shewn by the shadow, to give the hour required.

quired: the reason of which is, that the moon comes to the same horary circle later than the sun by about three quarters of an hour every day: and at the time of new moon the solar and lunar hori coincide.

DIALS, plane of. Having prepared the plane on which the dial is to rest, the hour may be found with tolerable accuracy by a large commodious ring-dial, to which a watch is to be set; and then the dial may be fixed by the watch at leisure. But in order to have the time more exactly, the sun's altitude should be taken by a good quadrant, and the precise time of observation noted by a clock or watch: then the time should be computed for the observed rhizoid, and the watch set to agree with that time. Otherwise, take two equal altitudes of the sun in the same day in summer, one between ten and ten in the morning, the other between two and five in the afternoon; mark the moments of the two observations by a clock or watch; and if the watch shows the observations to be at equal distances from noon, it agrees exactly with the sun; if not, the watch must be corrected by half the difference of the forenoon and afternoon intervals; and then the dial may be set true by the watch. To find a meridian line, see **MERIDIAN**.

It is necessary to observe, that if a dial be made according to the strict rules of calculation, and truly set at the instant, when the sun is in the meridian, it will be a minute too tall in the forenoon, and as much too low in the afternoon, by the shadow of the style; because the edge of the shadow that shows the time is even with the foremost edge of the sun in the forenoon, and with his hindmost edge in the afternoon, on the dial, whereas the sun's centre determines the time in the (supposed) hour circles of the heaven; and as the sun is half a degree in breadth, he takes two minutes to move through a space equal to his breadth; and there will be two minutes at noon in which the shadow will have no motion at all on the dial. It likewise appears, that if the dial be set true by the sun in the forenoon, it will be two minutes too low in the afternoon; and *vice versa*. The way of remedying this error, is to let every hour and minute division on the dial one minute nearer XII than the calculation requires. Ferguson's Tables and Tracts, p. 73, &c.

DIAL-PANES, plain superficies, upon which the hour-lines of dials are drawn. See **DIAL**.

DIAL, judicial. See **NOCTURNAL**.

DIAL, tide. See **TIDE-DIAL**.

DIALECT, dialectus, from *dialegomai*, to converse, the peculiar language of some province, or part of a nation, formed by corruption of the general, or national language.

Homer could speak five different languages in one verse, i. e. five dialects; viz. the Attic, Ionic, Æolic, Doric, and the common dialect of the Greeks.

The Attic dialect is more particularly used by Xenophon and Theophrastus; the Ionic by Herodotus and Hippocrates; the Doric by Pindar and Theocritus; the Æolic by Sappho and Alceus, and often by the two former writers.

The Bolognese, Bergamasque, Tuscan, &c. are the dialects of the Italian; the Galcon, and Picard, are dialects of the French.

In Great Britain, almost every county has a dialect of its own; all differing considerably in pronunciation, accent, and tone, though the language be the same.

The method which the Gileadites took to prove the Ephraimites, by the pronunciation of *shibboleth*, with *sh* or *f* instead, is well known. Judges xii. 6.

DIALECTICA, dialecticus, dialecticus, the art of reasoning and disputing fully.

The word comes from the Greek *διαλεκτικός*, *dialecticus*; formed of *dia*, and *lego*, *dia*, I say.

Zeno Eleates was the first who discovered the natural series of principles and conclusions observed in reasoning, and formed an art thereof, in form of a dialogue; which, for this reason, was called *Dialectica*.

The *Dialectica* of the ancients is usually divided into several kinds: the first was the *Eleatica*, that of Zeno Eleates, which was threefold; viz. *cataphorica*, *elenctica*, and *methememica*. The first consisting of rules for deducing, or drawing conclusions; the second, the art of dialogue; which became of such universal use in philosophy, that all reasoning was called *interrogation*: then, syllogism being laid aside, the philosophers did all by dialogue; i. e. lying on the respondent to conclude and argue from the several concessions made. The last part of Zeno's *Dialectica*, Epicurus, was contentious; or the art of disputing, and contradicting: though some, particularly Laertius, ascribe this part to Protagoras, a disciple of Zeno.

The second is the *Dialectica Megarica*, whose author is Euclid, not the mathematician, but another, of Megara. He gave much into the method of Zeno, and Protagoras,

though there are two things appropriated to him; the first, that he impugned the demonstrations of others, not by assumptions, but conclusions; continually making illations, and proceeding from consequence to consequence; the second, that he set aside all argument drawn from comparison, of similitude, as invalid. He was succeeded by Eubulides, from whom the epistemic way of reasoning is said to be derived. In his time the art is described as manifold; menippeus, eulianus, dialictus, obvelatus, arcuatus, cornutus, and calvus. See **SOPHISM**.

The third is the *Dialectica* of Plato, which he proposes as a kind of analysis, to direct the human mind by dividing, defining, and bringing things to the first truth; where being arrived, and stopping there a little, it applies itself to explain sensible things; but with a view to return to the first truth, where alone it can rest. Such is the idea of Plato's analysis.

The fourth is Aristotle's *Dialectica*, containing the doctrine of simple words, delivered in his book of *Prædicaments*; the doctrine of propositions, in his book *De Interpretatione*; and that of the several kinds of syllogisms, in his books of *Analytics*, *Topics*, and *Elenctics*.

The fifth is the *Dialectica* of the Stoics, which they call a part of philosophy, and divide into rhetoric, and *dialectica*; to which some add the definitive, whereby things are fully defined, comprehending, like wife, the canons, or criterions, of truth.

The Stoics, before they come to treat of *dialectica*, have two principal places; the one, about the signification of words; the other, about the thing signified. On occasion of the first, they consider abundance of things belonging to the grammarian's province: what, and how many letters; what is a word, diction, speech, &c. On occasion of the latter, they consider things themselves, not as without the mind, but as in it, received in it by means of the senses. Accordingly, they first teach, that *id est intellectus, quod non potest fieri in sensu*; whatever is in the mind, came thither by the senses; and that, *ut ex se fieri solent*, as Plato, who meets the light, and *similitudo*, as Cicero, by his ellipsis; *ut proportionem*, either by enlarging, as a giant; or by diminishing, as a pigmy; *ut transference*, as a Cyclops; *ut comparationem*, as a Centaur; *ut contrarietatem*, as death; *ut privationem*, as a blind man.

The sixth is Epicurus's *Dialectica*. For though he seems to have despised *dialectica*, he cultivated it with rigour; he was only averse to that of the Stoics, who, he thought, attributed too much to it; as pronouncing him alone wise, who was well versed in *dialectica*. For this reason, Epicurus, seeming to set aside the common *dialectica*, had recourse to another way; viz. to certain canons, which he substituted in their stead, the collection whereof he called *Canonica*; and as all questions in philosophy are either *de re*, or *de voce*, he gave separate rules for each. See **EPICURÆAN**.

DIALECTICAL arguments, in *Logic*, are such as are only probable, and do not convince, or determine, the mind absolutely to either side of the question.

DIALIA, in *Antiquity*, sacrifices performed by the *flamen dialis*, or priest of Jupiter.

It was not, however, of such absolute necessity, that the *Dialia* should be performed by the *flamen dialis*; but that others might officiate. We find in Tacitus, *Annal.* lib. ii. cap. 58. that if he were sick, or detained by any other public employ, the pontifices took his place.

DIALIS, in *Antiquity*, a Latin term, signifying somewhat that belongs to Jupiter.

The word is formed from *dius*, the genitive of *divus*, Jupiter.

DIALIA, Flaminia. See **FLAMINIA**.

DIALITHA, from *dia* and *lithos*, gem, in the *Writings* of the *Antients*, a word used to express the elegant ornaments of the Greeks and Romans, composed of gold and gems. They also called these *dialitha*, cemented stones or gems, the gold being in this case, as a cement, to hold the stones together. They wore bracelets, and other ornamental things about their habits, thus made; and their cups and table furniture for magnificent treats were of this kind. The green stones were found to succeed best of all in these things; and the emerald and greenish topaz, or, as we call it, chrysolite, are most in esteem for this purpose. This use of the stone explains what Piny very often says of them in his descriptions: *Nihil facundius aureum dicit: nihil gemis gemis dicitur*. Thus he says of the green topaz or chrysolite; and this, and many other like passages, have greatly perplexed the critics who did not hit upon this explanation. The Latin called these *dialitha*, *lithellus*, and *aureum gemmatum*; and thus Martial, where he says *mirator Scythicas vitæ uni flammis Jupiter*, alludes to cups of gold, ornamented with Scythian gems, that is, emeralds.

DIALIUM, in *Botany*, a genus of the *dianthus* microphylla.

clerk; the corolla has five petals, and there is no calyx. There is only one species.

DIALIACTERII, among the Athenians. See **DIALECTIC**.

DIALLELOS, *Συμμετρος*, in *Rhetoric*, a figure, wherein the words and meaning of a sentence are inverted, as *διὰ τὴν ἀρετὴν ἀφαιρῶν δόξαν*. Voss. *Rhet. lib. v. p. 205*.

DIALING, the art of drawing sun, moon, and star-dials, on any given plane, or on the surface of any given body. See **DIAL**.

The Greeks and Latins call this art *gnomonica*, and *scia-tistica*, because it distinguishes the hours by the shadow of a gnomon. Some call it *photocautaria*, because the hours are sometimes thrown by the light of the sun. Lastly, others call it *horiographia*.

Dialling is wholly founded on the first motion of the heavenly bodies, and chiefly the sun; or rather on the diurnal rotation of the earth; so that the elements of sphericity, and the spherical astronomy, should be mastered, before a person advances to the doctrine of dialling; the doctrine, or theory, we say for, as to the practice, or the operations themselves distinct from the demonstrations, nothing is more easy and obvious.

The principles of dialling may be easily deduced from the method, already illustrated, of constructing dials by the globe. Or, they may be further explained, by supposing the whole earth a *Pea* (*Tab. W. Dialling, fig. 36.*) to be transversed and bisected, like a sphere of glass, and its equator to be divided into twenty-four equal parts by 1200 meridian semicircles, of h, s, d, q, f, g , &c. one of which is the geographical meridian of any given place, as London, which is supposed to be at the point *a*, and if the hour of XII were marked at the equator, both upon that meridian and the opposite one, and all the rest of the hours in order on the other meridians, those meridians would be the hour circles of London; because, as the sun appears to move round the earth, which is in the centre of the visible heavens, in twenty-four hours, he will pass from one meridian to another in an hour. Then, if the sphere had an equatorial axis, as *PE*, terminating in the poles *P* and *E*, the shadow of the axis, which is in the same plane with the sun and with each meridian, would fall upon every particular meridian and hour, when the sun came to the plane of the opposite meridian, and would consequently show the time at London, and at all other places on the same meridian. If this sphere was cut through the middle by a solid plane *ABCD* in the rational horizon of London, one half of the axis *EP* would be above the plane, and the other half below it, and if straight lines were drawn from the centre of the plane to those points where its circumference is cut by the hour circles of the sphere, those lines would be the hour lines of an horizontal dial for London; for the shadow of the axis would fall upon each particular hour line of the dial, when it fell upon the like hour circle of the sphere. If the plane which cuts the sphere be upright, as *AFG* (*fig. 37.*) touching the given place, e. g. London, at *F*, and directly facing the meridian of London, it will then become the plane of an exact direct south dial; and if right lines be drawn from its centre *E*, to those points of its circumference where the hour circles of the sphere cut it, there will be the hour lines of a vertical or direct south dial for London, to which the hours are to be set in this figure, contrary to those on an horizontal dial; and the lower half *EP* of the axis will cast a shadow on the base of the dial in this dial, at the same time that it would fall upon the like hour circle of the sphere, if the dial plane was not in the way. If the plane, *ABD* facing the meridian, be made to incline, or recline, any given number of degrees, the hour circles of the sphere will still cut the edge of the plane in those points to which the hour lines must be drawn straight from the centre; and the axis of the sphere will cast a shadow on those lines at the respective hours. The like will still hold, if the plane be made to decline by any given number of degrees from the meridian towards the east or west; provided the declination be less than 90 degrees, or the inclination be less than the co-latitude of the place; and the axis of the sphere will be the gnomon otherwise, the axis will have an elevation above the plane of the dial, and cannot be a gnomon.

Thus it appears, that the plane of every dial represents the plane of some great circle on the earth, and the gnomon the earth's axis; the vertex of a right gnomon the centre of the earth or visible heaven; and the plane of the dial is just as far from this centre as from the vertex of the gnomon. The earth itself, compared with its distance from the sun, is considered as a point; and therefore, if a small sphere of glass be placed upon any part of the earth's surface, so that its axis be parallel to the axis of the earth, and the sphere hath fixed lines upon it, and such planes within it, as above described, it will show

VOL. II. N° 95.

the hours of the day as truly as if it were placed at the earth's centre, and the first of the earth were as transparent as glass. Pergulon, *ubi supra*.

The first professed writer on dialling, is Clavius; who demonstrates all, both the theory, and the operations, after the rigid manner of the ancient mathematicians; but so intricately, that probably no body ever read them at all: Dechales, Ozanam, and Sebotius, give much easier in their *Coefices*, and Wolfius in his *Elementis*. M. Picard has given a new method of making large dials, by calculating the hour lines; and M. de la Hire, in his *Dialling*, printed in 1683, a geometrical method of deriving hour lines from certain points, determined by observation. Eberhardus Walpers, in 1723, published his *Dialling*, wherein he lays down a method of drawing the primary dial on a very easy foundation. The same foundation is disabused at length by Sebastian Munster, in his *Recondita Mathematica*, published in 1721. Sturmius, in 1722, published a new edition of Walpers's *Dialling*, with the addition of a whole second part, about inclining, and declining dials, &c. In 1729, the same work, with Sturmius's additions, was republished with the addition of a fourth part, containing Picard's, and De la Hire's methods of drawing large dials, which makes much the best, and fullest book on the subject. Petersen, Michael, and Muller, have each written on *dialling*, in the German tongue; Coetius, in his *Horologographia Plana*, printed in 1669; Gassepian, in his *Gnomonica Mechanica*; Eschboorn, in his *Dialling*, &c. and Blon, in his *Use of Mathematical Instruments*. We have a treatise by Mr. Desargues, in 1708. Mr. Pergulon has also written on this subject in his *Lectures on Mechanism*.

DIALING CYLINDER UNIVERSAL, is represented by *fig. 38.* *ABCD* is a glass cylindrical tube, closed at both ends with brass plates, in the centre of which a wire or axis *EPG* is fixed. The tube is either fixed to an horizontal board *H*, so that its axis may make an angle with the board equal to that which the earth's axis makes with the horizon of any given place, and be parallel to the axis of the world; or it may be made to move on a joint, and elevated for any particular latitude. The twenty-four hour lines are drawn with a diamond on the middle of the glass, equidistant from each other and parallel to the axis. The XII next *B* stands for midnight, and the XII next the board *H* for noon. When the axis of this instrument is elevated according to the latitude, and the board set level, with the line *HN* in the plane of the meridian, and the end *N* towards the north; the axis *EPG* will serve as a gnomon or stile, and cast a shadow on the hour of the day among the parallel hour lines, when the sun shines on the instrument. As the plate *AD* at the top is parallel to the equator, and the axis *EPG* perpendicular to it, right lines drawn from the centre to the extremities of the parallels will be the hour lines of an equinoctial dial, and the axis will be the stile. An horizontal plate *ef* put down into the tube, with lines drawn from the centre to the several parallels cutting its edge, will be an horizontal dial for the given latitude; and a vertical plate *eg*, fronting the meridian and touching the tube with its edge, with lines drawn from its centre to the parallels, will be a vertical south dial; the axis of the instrument serving in both cases for the stile of the dial; and if a plate be placed within the tube, so as to decline, incline, or recline, by any given number of degrees, and lines be drawn, as above, a declining, inclining, or reclining dial will be formed for the given latitude. If the axis with the several plates fixed to it be drawn out of the tube, and set up in function in the same position as they were in the tube, *AD* will be an equinoctial dial; *ef* an horizontal dial, and *eg* a vertical south dial; and the time of the day will be shown by the axis *EPG*. If the cylinder were wood, instead of glass, and the parallel lines drawn upon it in the same manner, it would serve to facilitate the operation of making these several dials. The upper plate with lines drawn to the several intersections of the parallels, which appear obliquely in *fig. 38.* would be an equinoctial dial as in *fig. 39.* and the axis perpendicular to it be its stile. An horizontal dial for the latitude of the elevation of the axis might be made, by drawing out the axis and cutting the cylinder, as at *EPG*, parallel to the horizontal board *H*; the section would be elliptic, as in *fig. 40.* A circle might be described on the centre, and lines drawn to the divisions of the ellipse would be the hour lines; and the wire put in its place again, as *E*, would be the stile. If this cylinder were cut by a plane perpendicular to the horizontal board *H*, or to the line *SHN*, beginning at *P*, the plane of the section would be elliptic, as in *fig. 41.* and lines drawn to the points of intersection of the parallels on its edge would be the hour lines of a vertical direct south dial, which

might

might be made of any shape, either circular or figure; and F the axis of the cylinder would be its stile. Thus also inclining, declining, or reclining dials might be easily constructed, for any given latitude. Ferguson, ubi supra.

DIALING GLOBE, is an instrument made of brass, or wood, with a plane fitted to the horizon, and an index, particularly contrived to draw all sorts of dials, and to give a clear exhibition of the principles of that art.

DIALING LINE, or **Stiles**, are graduated lines, placed on rules, or the edges of quadrants, and other instruments, to expedite the construction of dials.

The principal of these lines are, 1. A scale of six hours, which is only a double tangent, or two lines of tangents each of 45 degrees, joined together in the middle, and equal to the whole line of lines, with the declination set against the meridian altitudes in the latitude of London, suppose, or any place for which it is made: the radius of which line of lines is equal to the *secant* part of six hours. 2. A line of latitudes, which is fitted to the hour scale, and is made by this canon: as the radius is the chord of 90 degrees; so are the tangents of each respective degree of the line of latitudes, to the tangents of other arches; and then the natural sines of those arches are the numbers, which, taken from a diagonal scale of equal parts, will graduate the divisions of the line of latitude to any radius. The line of hours and latitudes is generally for pricking down all dials with centres. For the method of constructing these scales, see **SCALES**.

DIALING SPHERE, is an instrument made of brass, with several femicircles sliding over one another, on a moving horizon, to demonstrate the nature of the doctrine of spherical triangles, and to give a true idea of the drawing of dials on all manner of planes.

DIALING, in a *Ship*, called also *Plumbing*, is the using of a compass (which they call *dial*), and a long line, to know which way the lead, or vein of ore lies, or where to shaft an adit, or being an adit to a desired place. See **MINE**, and **PLUMBING**.

DIALOGISM, *Διαλογισμός*, in *Rhetoric*, is used for the Soliloquy of persons deliberating with themselves. We have an instance of it in Virgil, where Dido says,

*En quid agam? rursus prius erris prius
Supplicis Eto.*

In which sense, it is distinguished from *dialogue*. Voss. Rhet. lib. v. p. 555. See **DIALOGUE**.

DIALOGISM is also taken in a more extensive sense for discourse in general, whether held by a person alone, or in company.

DIALOGUE, is a conversation of two, or more persons, real or feigned, either by word of mouth, or in writing. The word is formed from the Latin *dialogus*, of the Greek *διαλογος*, which signifies the same.

Dialogue is greatly recommended by many authors, and is the most ancient form of writing; and that wherein the first authors wrote most of their pieces. The archbishop of Cambrai gives a fine account of the advantages of *dialogue*, at the head of his pastoral instruction. The sacred writers, and the fathers Athanasius, Basil, Chrysostom, &c. have used this mode of instruction.

Antiquity made use of *dialogue*, not only on humorous and comical subjects, as Lucian did, but also on the most serious and illustrious: such are the *Dialogues* of Plato, and those of Cicero, which turn altogether on subjects of philosophy, or politics. Among the moderns, the principal dialogues are M. de Fenelon, archbishop of Cambrai; M. Pascal, in his Provincial Letters; P. Bouhours, in his Entretiens d'Ariste, &c. d'Eugene; M. Ponsseville, in his Dialogues of the Dead, and Plurality of Worlds; Addison, Hurd, and Lord Lyttelton.

A *dialogue* consists of two parts, an introduction and the body of the discourse. The introduction acquaints us with the place, time, persons, and occasion of the conversation. However, the introduction ought not to be too long and tedious. Mr. Addison complains of this fault; for though, as he says, some of the finest treasures of the most polite Latin and Greek writers are in *dialogue*, as many very valuable pieces of French, Italian, and English appear in the same dress; yet in time of them there is so much time spent up in ceremony, that before they enter on their subject, the *dialogue* is half over. Dial. II. of Menap. init. As to the body of the discourse, care should be taken, to keep up a justness of character in the persons that are introduced through the whole of the *dialogue*; and the characters should be so discriminated, that it may be known from the words themselves, who is the speaker. The principal speaker should appear to be a person of great sense and wisdom, and intimate acquaintance with the subject; and he should be capable of fairly answering every question that may be asked, and every objection that may be started.

In the whole discourse, all wrangling, peevishness, and obstinacy should be avoided; and nothing appear but good humour and good breeding, with a readiness to submit to conviction, as evidence presents itself. Cicero has given us two characters of this kind in Cato and Antony; from whom Mr. Addison seems to have taken his Philander and Cynio, in his *Dialogues on the Usefulness of Ancient Medals*. If younger persons are introduced, they should rather inquire than dispute, and neither be too long nor too frequent in the questions they propose. Sulpicius and Cato are made to sustain this character by Cicero, and Seneca by Mr. Addison. A person of humour may also be introduced to enliven the discourse, as Cato by Cicero, and Cynio by Mr. Addison. With regard to the subject of a *dialogue*, all the arguments should at least appear probable, and nothing be advanced, which may seem weak or trivial. Short and pleasant discourses are allowed, but they should not interrupt the thread of the discourse, and break the union of the parts and constant reference to the main end, which are essential to a *dialogue*. The time allowed for a *dialogue* has been various; Cicero allows two days for his three *dialogues* concerning an orator; but Mr. Addison permits his to three days, allowing a day for each. The method of composing *dialogues* has likewise been various; sometimes a *dialogue* is composed, by way of narrative, which is the manner of Lucian; or perit; such are the *dialogues* of Seneca, and Mr. Addison last mentioned; at other times the *dialogues* are introduced in person; Cicero's *Dialogues* of Old Age, of Friendship, and of the Parts of Oratory, are written in this manner. Plato and Lucian generally choose this method. As far the stile of a *dialogue*, the low style is the proper character, in which they should generally be written. Ward's Orat. vol. ii. p. 221, &c.

DIALOGUE, in *Music*, is a composition for at least two voices, or two instruments, which answer each other; and which frequently ending in the close, make a *trio* with the thorough-bass.

Such are many of the scenes in the Italian and French operas.

DIALTHAEA, in *Pharmacy*, an ungular, thus called from its basis, which is root of the *aphes*, or *marsh hallow*. It consists of mucilages drawn from that root, and from linseed and hempseed seed. The other ingredients are common oil, wax, resin, and turpentine.

It is esteemed proper to soften, and dissolve; assuage pains of the spleen, intestines, and throughout the nerves. It is applied by rubbing it on the part affected.

DIALYSIS, in *Chemistry*, a character, consisting of two points or placed over two words of a word, which would otherwise make a disphenon; but are thereby parted into two syllables; as in *Moloss*. See **DIACRISIS**.

DIAMARGARITON, in *Pharmacy*, a medicine denominated from pearls, called, in Latin, *margarita*, which are a principal ingredient therein.

There are two kinds, the *hot*, and the *cold*; but both are dissolved at this time.

DIAMARGARITON, *Hot*, is a powder composed of pearls, peltory, ginger, nutmeg, cinnamon, and divers other hot ingredients. It is reputed hystric; it strengthens the stomach, promotes the appetite, and kills digestion.

DIAMARGARITON, *Cold*, is a solid electry, composed of pearls ground fine, and white sugar dissolved in rose water, or that of bugloss, and boiled to a consistence. It strengthens the stomach, moderates the too abundant acids, stops the spitting of blood, and loosens the belly.

DIAMARGARITON, *Compound Cold*, is a powder made of pearls, red roses, flowers of musphar, and silver, lixivum sweet, red and citren distil, turmeric root, seeds of melon, radish, &c. It is curative and strengthening, freestates repletion, and corrects malignant humours.

DIAMARTYRIA, *Διαμαρτυρία*, in *Medicine*, a prescription that the deceased person had left in writ, made to bind the relations from entering upon the estate. Potter, Archæol. Græc. tom. II. lib. I. cap. 24. p. 118.

DIAMASTIGOSIS, in *Anatomy*, is a wound among the Lacedæmonians, for the children of the most distinguished families to lash and tear each other's bodies with rods before the altars of the gods, the fathers and mothers, who were present at the spectacle, animating and exhorting them all the while, not to give the least sign of pain or concern. This practice they called *diastigsis*, a Greek term, derived from *diastasis*, to *tear*, *to pierce*. The design thereof, apparently, was to offer them to harden their youth, and infuse into them to blows, wounds, &c. that they might despise pain when they came to war.

DIAMBRAE species, in the *Materia Medica*, the name of two medicines in the London Dispensary, the one called *spiritus diambrae sine tharaxi*, the other, *spiritus diambrae*.

ambra cum odoribus, from the ambergris in their composition. The *spiced diambra* without perfume, is originally a prescription of Meisius, and exactly transcribed from him into their Dispensatory. This is esteemed a great cephalic and cordial, and is frequently prescribed in nervous decays, from apoplexies, epilepsies, palsies, and old age. It strengthens the stomach in particular, raises the spirit, and warms the blood to a very great degree; it is thereby a provoker to venery, but more as a stimulus than by supplying any fresh recruits, or augmenting the ability. Its dose is from ten grains to half a dram. James.

DIAMETER, from *dia*, and *metron*, to measure, in Geometry, a right line passing through the centre of a circle, and terminated on each side by the circumference thereof.

Or, *diameter* may be defined a chord passing through the centre of a circle. Such is the line AE (*Tab. Geomet.*, fig. 24.) passing through the centre C. Hence the *diameter* is the greatest of all chords.

Half a *diameter*, as CD, drawn from the center C to the circumference, is called the *semi-diameter*, or *radius*. The *diameter* divides the circumference into equal parts. And hence we have a method of describing a semicircle upon any line, assuming a point therein for the centre.

To find the ratio of the **DIAMETER** to the circumference. This has been greatly sought for by the mathematicians, and no wonder, inasmuch as if this were fully given, the quadrature of the circle were achieved.

Archimedes first proposed a method of finding it, by regular polygons inscribed in a circle, till arriving at a side subtending an exceeding small arch, and then looking a side of a similar polygon circumscribed; each of these being multiplied by the number of sides of the polygon, give the perimeters of the polygons both inscribed and circumscribed. In which case the ratio of the *diameter* to the circumference of the circle, is greater than that of the same *diameter* to the perimeter of the circumscribed polygon, but less than that of the *diameter* to the perimeter of the polygon inscribed. The difference between both gives the ratio of the *diameter* to the circumference in numbers nearly true.

That celebrated author, as already observed, by polygons of 96 sides, found the ratio of the *diameter* to the circumference to be as 7 to 22 $\frac{1}{7}$; viz. supposing the *diameter* 1, the perimeter of the inscribed polygon is found $\frac{1}{2}$, and that of the circumscribed $\frac{1}{2}$.

After his example, later authors have found out ratios yet nearer truth; Wellesius finds it as 10000000000000 to 31415926535897932; but none spent so much time on it as Van Ceulen, who, after immense pains, found that supposing the *diameter* 1, the circumference is less than 3.141592653589793238462643383279505, and yet greater than the same number with only the last figure 0 changed into 1. Mr. A. Sharp doubled Van Ceulen's numbers; and this is so near the truth, that the *diameter* of the earth being given, we might from thence compute the number of lands equal to the Earth, contents of the earth, so near as not to differ one grain of sand from the truth. Mr. Machin carries them at one hundred places; thus the circumference of a circle whose *diameter* is 1, will be 3.141592653589793238462643383279505284197169399375105821797494459230136095028998628034853441752979.

But as such precise numbers are too unwieldy for practice, many of our present practical geometers assume the *diameter* to be to the circumference as 100 to 314; or in greening circles as 10000 to 314159, in which proportion Ptolemy, Vietas, and Haygonius, agree with Van Ceulen. Ad. Metius gives us the ratio 113 to 355, which is the most accurate of all those expressed in small numbers; as not erring 1 in 10000000. Those in common use are Archimedes', Metius', or the proportion of 1 to 3.14159.

The **DIAMETER** of a circle being given, to find the circumference, and area, and the circumference being given, to find the *diameter*. The ratio of the *diameter* to the circumference being had, as in the last article, that of the circumference to the *diameter* is had likewise. Then the circumference, being multiplied into the fourth part of the *diameter*, gives the area of the circle. Thus, if the *diameter* be 100, the circumference will be 314, and the area of the circle 7850. But the square of the *diameter* is 10000; therefore, this is to the area of the circle as 10000 to 7850, that is, as 1000 to 785 nearly.

The area of the circle being given, to find the **DIAMETER**. To 785, 1000, and the given area of the circle 246179, find a fourth proportional, viz. 311360, which is the square of the *diameter*. Out of this extract the square root, and it is the *diameter* itself.

DIAMETER of a cone *solidus*, is a right line, as AD (*Tab.*

Cone, fig. 54) bisecting all the ordinates MM, &c. in P. See *Sec. Conic*.

This, when it cuts the said lines at right angles, is more particularly called the *axis of the cone*, or *solidus*.

DIAMETER, *Transversus*, is a right line, as AB (*Tab. Conic*, fig. 6. N^o 2.), which being continued each way between two curves, bisects parallel right lines between the same, as MM.

DIAMETER, *Conjugatus*, is a right line, bisecting lines drawn parallel to the *transverse diameter*. See *Conjugate*.

DIAMETER of a sphere, is the diameter of the semicircle by whose rotation the sphere is generated; called also the *axis of the sphere*.

DIAMETER of gravity, is a right line passing through the centre of gravity.

DIAMETER, in Astronomy. The *diameter* of the heavenly bodies are either *apparent*, i. e. such as they appear to the eye; or *real*, i. e. such as they are in themselves.

The *apparent diameters* measured with a micrometer, are found different, in different circumstances, and parts of their orbits. These are the angles under which the *diameters* of the planets are seen from the earth; and they are equal to the *real diameters* divided by the distance from the earth; or, as their angles are very small, the *diameter* may be taken for arcs of a circle described on the eye as a centre, with a radius equal to the distance of the planets; and they are said to consist of so many minutes and seconds as these angles consist of; therefore the *apparent diameter* of a planet is in the inverse ratio of their real distance. The sun's vertical *diameter* is found by taking the height of the upper and lower edge of his disk, when he is in or near the meridian; the height of each edge must be corrected by proper allowances for parallel air refraction, and the difference between these heights of the upper and lower edges is the *true diameter*. The sun's *apparent diameter* may be determined by observing with a good clock the time which the sun's disk takes in passing through the plane of the meridian, or some other hour circle.

If the sun is in or near the equator, the following proportion may be used a *viz.* as the time between the sun's leaving the meridian or any other hour circle and returning to it again, is to 360 degrees, so is the time of the sun's transit to the number of minutes and seconds of a degree contained in his *apparent diameter*. If the sun is in a parallel at some distance from the equator, his *diameter* measures a greater number of minutes and seconds than that parallel than it would do in a great circle, and takes up proportionally more time in passing over the meridian, in which case too, as the whole time is in the cosine of the sun's declination, so is the time of the sun's passing the meridian reduced to minutes and seconds of a degree, to the arc of a great circle which measures the sun's *apparent horizontal diameter*. See *TRANSIT*.

The sun's *apparent diameter* may also be taken by the projection of his image in a dark room.

There are several ways of finding the *apparent diameters* of the planets; but the most certain method is that with the micrometer.

The great difference between Tycho, and the other two astronomers, Hecilius and Huygens, is owing to this, that Tycho, in estimation of the *apparent* diameter, measured the diameter, as they appeared to the naked eye; whereas they used telescopes, whereby a deal of spurious lustre, which otherwise makes them appear bigger than they are, is taken off; nevertheless, the *diameters* of the planets measured by Huygens's method are somewhat bigger than they ought to be, because the rays of light are inflected as they pass by the edges of solid bodies, so which his method of observing was liable. On the other hand, Flamsteed's micrometer inflected the rays the contrary way, and gave their *apparent diameters* too small; and therefore Whiston chose the mean between the diameters of Huygens and Flamsteed.

The mean *diameters* of the planets as seen from the sun are as follow: viz. that of Mercury, 20%; of Venus, 30%; of the Earth, 11%; of the Moon, 6%; of Mars, 11%; of Jupiter, 37%; and of Saturn, 10%. See PARALLAX.

The following table shows the *apparent diameters* of the sun at different times of the year.

January	1 12 48.4	July	1 11 38.8

For the true *diameters* of the sun, and planets, and their proportion to each other, see PLANETS, and SEMI-DIAMETER.

Diameter of a column, is its thickness just above the base. From this the module is taken, which measures all the other parts of the column.

Diameter of the Dismounting is that taken from the top of the shaft. See DISMOUNTING.

Diameter of the fueling, is that taken at the height of one third from the base.

DIAMNES, a word used by Johannes Anglicus, and some other authors, for an involuntary discharge of urine.

DIAMOND, in Natural History, by the ancients called *adamas*, a precious stone, the first in rank, value, hardness, and lustre, of all gems.

The *properties of diamonds* consists in their water, or calcareous, lustre, and weight. The most perfect colour is the white. Their defects are veins, flaws, specks of red or black dust, and a bluish or yellowish taint.

Some chemical writers have maintained that *diamonds* are refractory in the fire, and even approve themselves, experiments have been made, which prove that they are capable of being dissipated, not only by the collected heat of the sun, but also by the heat of a furnace.

A *diamond*, by exposure to a concave speculum, the diameter of which was forty inches, was reduced to an eighth part of its weight, Phil. Trans. N° 386; and in some experiments made on precious stones, by order of the grand duke of Tuscany, with a burning lens, the diameter of which was two thirds of a Florence ell, near the focus of which was placed another smaller lens, happened that a *diamond* weighing thirty grains, exposed during thirty seconds, lost its colour, lustre, and transparency, and became of an opaque white. In five minutes, bubbles appeared on its surface; soon afterwards it burst into pieces, which were dissipated; and the small fragment which remained was capable of being crushed into fine powder by the pressure of the blade of a knife. No addition of glass, flint, sulphur, metals, or salt of tartar prevented this dissipation, or occasioned any degree of fusion. Experiments were also made by order of the emperor Francis I. on precious stones, from which we find, that *diamonds* were entirely dissipated by having been exposed in crucibles to a violent fire of a furnace during twenty-four hours; and when they were exposed during two hours only at a time, they were observed first to lose their polish, then to split into thin plates, and lastly, to be totally dissipated. M. D'Arcy has found, that *diamonds* may not only be perfectly dissipated by being exposed, in porcelain crucibles close, or covered with perforated lute, to the long and intense heat of a porcelain furnace; but that they may be totally volatilized with a much inferior degree of heat, by exposing them in a copper under the muffle of an assay furnace. He observed in this experiment, that the dissipation was gradual, and that it was effected by a kind of exhalation; M. Macquir, who repeated the experiments, farther observed,

served, that, before the dissipation began, the diamonds were by the fire rendered brilliant and shining, with a kind of phosphoric light. In order to determine whether diamonds were dissipated by evaporation or combustion, Messrs. Lavoisier, Laplace, and Cadet, exposed them to an intense heat in an earthen retort, during several hours, without any other effect than the loss of their polish, and about one seventh diminution of their weight.

M. Mitgard put diamonds in a tobacco-pipe filled with pounded charcoal, and accurately closed with lute; and in order farther to secure them from the access of air or flame, he placed the tobacco-pipe in a crucible to which another crucible was inverted and carefully luted: the result was, that the diamonds, thus exposed to the most intense heat, were not altered or diminished; which he ascribes not merely to the exclusion of air, but to some peculiar property of the charcoal; and he was confirmed in this opinion by finding, that they were not so well preserved by powder of chalk, or of calcined barithorn. M. Cadet exposed diamonds in covered and luted crucibles to the violent heat of a forge during two hours; by which operation they lost only one sixteenth part of their weight; and he concludes, that the destruction of them by fire in open vessels is not a true volatilization, as M. D'Arcet imagines, but merely an exfoliation, caused by the fire expanding the air contained between the thin plates of which the stones consist, and that by this exfoliation, the plates are reduced to so fine a powder as to escape observation. M. Lavoisier has lately made some curious experiments on diamonds with Tschirnhausen's great burning lens; from which he infers, that the diamond is a substance properly combustible, even in a moderate degree of heat; that, like other combustible bodies, it exhibits a black sooty matter at its surface; that when its combustion is prevented, through the want of air, it becomes almost as fixed in the fire as charcoal; but that in exposing it to the extremest degree of heat, it is capable of being reduced in part into an incoercible vapour, or a kind of gas, possessing the properties of that which is produced from effervescent and fermenting mixtures, and in metallic reductions. He also found, that when a diamond was exposed to the focus of the lens *in vacuo*, its transparency was not diminished; but that it was at length reduced into elastic or aerial vapours. *Dict. Chem. Eng. ed. 1777; and Hist. Acad. Sc. an. 1772. Mem. 1. and 2.*

In Europe, the lapidaries examine the goodness of their rough diamonds, their water, points, &c. by day-light: in the Indies, they do it by night; in order to which, a hole is made in the wall a foot square, and therein a lamp is placed, with a thick wick, by the light whereof they judge of the stone, holding it in their fingers.

The water called *calafiss* is the worst of all, and yet is somewhat difficult to discover in a rough diamond. The only infallible way is to examine it in the shade of some tufted tree.

The diamond becomes luminous in the dark by exposure during a certain time to the rays of the sun, by heating it in a crucible, by plunging it in boiling water, or by rubbing it with a piece of glass. It also acquires an electrical property by friction, and attracts light bodies. Dr. Wall has applied these properties as *criteria* for distinguishing diamonds from other precious stones; but they are not peculiar to diamonds, and therefore an insufficient test. *Phil. Trans. vol. iv. part ii. p. 277. See GAS, PHOSPHORUS, TOURMALIN, &c.*

The diamond is by some reckoned poisonous; others will not admit it into the list of poisons. The accounts in favour of diamonds are more numerous, as well as more credible, than those which would make us believe them to be of a poisonous nature.

Diamonds are found in the East Indies, principally in the kingdoms of Golconda, Visnapor, Bengal, and the island of Borneo. There are four mines, or rather two mines and two rivers, whence diamonds are drawn. The mines are, 1. That of Raolconda, in the province of Carnatica, five leagues from Golconda, and eight or nine from Visnapor. It has been discovered about 250 years. 2. That of Gani, or Coulour, seven days journey from Golconda, eastwardly. It was discovered about 170 years ago by a peasant; who, digging in the ground, found a natural fragment of twenty-five carats. 3. That of Soumelpour, a large town in the kingdom of Bengal, near the diamond-mine: this is the most ancient of them all. It should rather be called that of Goual, which is the name of the river, in the sand whereof these stones are found. Lastly, the fourth mine, or rather the second river, is that of Succudan, in the island of Borneo.

DIAMOND-MINE of Raolconda. In the neighbourhood of this mine the earth is sandy, and full of rocks, and coppers: in these rocks are found several little veins, of half, and sometimes a whole inch broad, out of which the miners,

with a kind of hooked iron, draw the sand, or earth, wherein the diamonds are; breaking the rocks when the vein terminates, that the track may be found again, and continued. When a sufficient quantity of earth, or sand, is drawn forth, they wash it two or three times, to separate the stones therefrom: the miners work quite naked, except for a thin linen cloth before them; and, besides this precaution, they have likewise inspectors, to prevent their concealing of stones: which, however, in spite of all their care, they frequently find means to do, by watching opportunities, when they are not observed, and swallowing them down.

DIAMOND-MINE of Gani, or Coulour. In this mine are found a great number of stones from ten to forty carats, and even more; and it was there that the famous diamond of Aureng Zeb, the great mogul, which, before it was cut, weighed 793 carats, was found. The stones of this mine are not very clear; their water is usually tinged with the quality of the soil; being black, where that is marly; red, where it partakes of reds; and sometimes green, and yellow, if the ground happen to be of those colours. Another defect, of some consequence, is, a kind of grassiness appearing on these diamonds, when cut, which takes off part of their lustre. They are usually no less than sixty thousand persons, men, women, and children, at work in this mine.

When the miners have found a place where they intend to dig, they level another, somewhat bigger, in the neighbourhood thereof, and enclose it with walls about two feet high, only leaving apertures, from space to space, to give passage to the water; after a few superfluous ceremonies, and a kind of feast, which the master of the mine makes for the workmen, to encourage them, every one goes to his business, the men digging the earth in the place first discovered, and the women and children carrying it off into the other, walled round. They dig twelve or fourteen feet deep, and till such time as they find water; then they cease digging; and the water, thus found, serves to wash the earth two or three times; after which, it is let out at an aperture reserved for that purpose. This earth being well washed, and well dried, they sift it in a kind of open sieve, or riddle, much as we do corn in Europe; then they thrash it, and sift it afresh; and, lastly, they search it well with the hands, to find the diamonds. They work naked here, as in the mine of Raolconda, and are watched, after the like manner, by inspectors.

DIAMOND-MINE of Soumelpour, or river Goual. Soumelpour is a large town built all of earth, and covered with branches of cacao-trees: the river Goual runs by the foot thereof, in its passing from the high mountains, towards the south, to the Ganges, where it loses its name. It is from this river that are brought all our fine diamond-points, or sparks, called *natural sparks*. They never begin to seek for diamonds in this river till after the great rains are over, that is, after the month of December; and they usually even wait till the water is grown clear, which is not before January: the season at hand, eight or ten thousand persons, of all ages, and both sexes, come out of Soumelpour, and the neighbouring villages. The most experienced among them search and examine the sand of the river; going up it from Soumelpour to the very mountain whence it springs. A great sign that there are diamonds near, is, the finding of those stones which we Europeans call thunder-stones. When all the sand of the river, which at that time is very low, has been well examined, they proceed to take up that wherein they judge diamonds likely to be found; which is done after the following manner: they dam the place round with stones, earth, and fascines; and, lading out the water, dig about two feet deep: the sand, thus got, is carried into a place walled round on the bank of the river. The rest is performed after the same manner as at Coulour, and the workmen are watched with equal strictness.

DIAMOND-MINE in the island of Borneo, or river of Succudan. We are but little acquainted with this mine; the prince who reigns in that part of the island not allowing strangers to have any commerce in these rivers: though there are very fine ones to be bought at Batavia, brought thither by stealth. They were anciently imagined to be better than those of the other mines; but experience shews, they are in no respect inferior to them.

Beside these four diamond-mines, there have been two others discovered: one of them between Coulour and Raolconda, and the other in the province of Carnatica: but they were both closed up almost as soon as discovered; that of Carnatica, because the water of the diamonds was always either black, or yellow; and the other, on account of their cracking, and flying in pieces when cut and ground.

Diamond-mines were discovered about the year 1728 in

the Bravils belonging to the king of Portugal, who in the year 1740 let them to a company at Rio Janeiro, for a certain stipulated annual rent, which is said to be 130,000 cruzaes, on condition that the said company employ no more than six hundred slaves in working them; since which time the value of diamonds is diminished.

The diamonds, we have already observed, is the hardest of all precious stones. It can only be cut, and ground, by itself and its own substance. To bring it to that perfection which augments its price so considerably, they begin by rubbing several against each other, while rough; after having first glued them to the ends of two wooden blocks, thick enough to be held in the hand: it is the powder thus rubbed off the stones, and received in a little box for the purpose, that serves to grind and polish the others.

Diamonds are cut and polished by means of a mill, which turns a wheel of soft iron sprinkled over with diamond dust mixed with oil of olives: the same dust, well ground, and diluted with water and vinegar, is used in the sawing of diamonds; which is performed with an iron or brass wire, as fine as a hair: sometimes, in lieu of sawing the diamonds, they cleave them, especially if there be any visible plates in them; but the Europeans are not usually daring or expert enough, to run the risk of cleaving, for fear of breaking.

DIAMOND, Rough, is that not yet cut, but just as it comes out of the mine.

A rough diamond must be chosen uniform, of a good shape, transparent, of a quite white, and free of flaws and shivers. Rough diamonds are more commonly found of a six-pointed figure than of any other; and these are called *six-pointed rough diamonds*, the figure of which is composed of two square pyramids, joined at their bases. Hence the whole figure is composed of eight triangular faces, or planes, four of which meet in a point above the base, and four below it in another point. The distance of these two points is the axis of the figure.

There are others flat, cubical, or rounded: the former are the best and hardest; the latter sort are softer, and more liable to have their forms altered by attrition. Diamonds are said to consist of laminae or plates, and probably have some uniform texture; because lapidaries find that they may be polished much more easily in one than in any other direction.

Black, rugged, dirty, flawed, veiny stones, and all such as are not fit for cutting, they use to pound in a steel mortar made for that purpose; and, when pulverized, they serve to saw, cut, and polish the rest. Shivers are occasional, in diamonds, by this; that the miners, to get them more easily out of the vein, which winds between two rocks, are often forced to break the rocks with huge iron wedges, which shakes and fills the stone with cracks and shivers. The ancients had two mistaken notions with regard to the diamond: the first, that it became lost, by soaking it in hot goat's blood; and the second, that it was malleable, or bore the hammer. Experience shews us the contrary: there being nothing capable of mollifying the hardness of this stone; though its hardness be not such, that it will endure being struck at pleasure with the hammer.

DIAMOND, Brilliant, is that cut in faces both at the top, and bottom; and whole table, or principal face at the top, is flat.

To make a complete square brilliant, if the rough diamond be not found to be of the figure here described, it must be made so. And if the work be perfectly executed, the length of the axis will be equal to the side of the square base of the pyramid. Jewellers then form the table and collet, by dividing the block or length of the axis into eighteen parts. They take $\frac{1}{2}$ from the upper part, and $\frac{1}{2}$ from the lower. This gives a plane at $\frac{1}{2}$ distance, from the girdle for the table; and a smaller plane at $\frac{1}{2}$ distance, for the collet; the breadth of which will be $\frac{1}{2}$ of the breadth of the table. In this state the stone is said to be a complete square table diamond.

The brilliant is an improvement on the table diamond, and was introduced within the last century, according to Mr. Jeffries.

To render a brilliant perfect, each corner of the above described table diamond must be shortened by $\frac{1}{4}$ of its diagonal. The corner ribs of the upper sides must be flattened, or run towards the centre of the table; less than the sides. The lower part which terminates in the girdle, must be $\frac{1}{4}$ of one side of the girdle; and each corner-rib of the under sides must be flattened at the top, to answer the above flattening at the girdle, and at bottom must be $\frac{1}{4}$ of each side of the collet.

The parts of the small work which complete the brilliant,

or the star and skill facets, are of a triangular figure. Both of these partake equally of the depth of the upper sides, from the table to the girdle, and meet in the middle of each side of the table and girdle, as also at the corners. Thus they produce regular lozenges on the four upper sides and corners of the stone. The triangular facets, on the under sides, joining to the girdle, must be half as deep again as the above facets to answer to the collet part.

The stone here described is said to be a full-job brilliant.

If the stone be thicker than in the proportion here mentioned, it is said to be an over-weighted brilliant.

If the thickness be less than in this due proportion, it is called a spread brilliant.

The beauty of brilliants is diminished by their being either over-weighted or spread. The true proportion of the axis or depth of the stone to its side, is as 2 to 3.

Brilliant is distinguished into square, round, oval, and drops, from the figure of their respective girdles.

DIAMOND, Rose, is that quite flat underneath, but its upper part cut in diverse little faces, usually triangles, the uppermost whereof terminate in a point. In rose diamonds, the depth of the stone from the base to the point must be half the breadth of the diameter of the base of the stone. The diameter of the crown must be three fifths of the diameter of the base. The perpendicular from the base to the crown must be three fifths of the depth of the stone. The lozenges, which appear in all circular rose diamonds, will be equally divided, by the ribs that form the crown; and the upper angles, or facets, will terminate in the extreme point of the stone, and the lower in the base or girdle.

The taste which now prevails of converting rose-diamonds into brilliants, is condemned by Mr. Jeffries, unless the rose diamonds be over-weighted. He thinks, that the display of beauty in rose-diamonds, is often preferable to that of brilliants. See his Treatise on Diamonds, p. 32, 35.

DIAMOND, Table, is that which has a large square face at the top, encompassed with four lesser.

DIAMONDS, Compensum is. The finest diamonds are those of a complexion like that of a drop of the clearest rock-water; and if such stones be of a regular form, and truly made, as also free from stains, spots, specks, flaws, and cross veins, they will have the highest lustre of any, and be esteemed the most perfect.

If diamonds be tinged yellow, blue, green, or red, in a high degree, they are next in esteem. But if they partake of these colours only in a low degree, it greatly sinks their value.

There are other complexions of diamonds, such as the brown, and those of a dark hue; the first sometimes resemble the brownest sugar-candy, and the latter dusky iron. A black tinge in diamonds is considered as an imperfection, though, when the diamond is cut, a black fall placed under it improves its beauty; for the rose diamonds, the collet or socket in which the stone is set, is specked with ivory black in little dots; and for brilliants, it is all over blacked. Dr. Lewis mentions a black diamond cut and set in a ring, which at a distance looks uniformly black, but, on closer examination, appears in some parts transparent, and in others charged with foulness, on which the black hue depends. Commerce of Arts, p. 637.

The first water in diamonds means the greatest purity and perfection of their complexion, which ought to be that of the clearest drop of water.

When diamonds fall short in this perfection, they are said to be of the second or third water, &c. till the stone may be properly called a coloured one: for it would be an impropriety to speak of a diamond imperfectly coloured, or having other defects, as a stone of a bad water only.

DIAMONDS, Magnitude of. The most remarkable diamonds for size now known, are, that known in France under the name of *grand juif*, by corruption of *cut juif*, which is one of the crown jewels, weighing 106 carats; governor Pitt's diamond, purchased by the late duke of Orleans for Louis the XV. king of France, weighing 136 carats, and said to be bought for 175000l. the diamond of the great duke of Tuscany, which weighs 139 carats; that of the great Mogul, weighing 279 carats; and one mentioned by Mr. Jeffries, in a merchant's hands, weighing 222 carats.

DIAMONDS, Valuation of. The following is a rate, or manner of estimating the value of diamonds, drawn up by a person well versed in such matters; and which, for its curiosity, as well as the use it may be of to persons who deal in precious stones, we judge, will not be unacceptable.

D I A

Table of DIAMONDS.

Dutch Cut.

A Diamond weighing 1 grain, is worth from	Lib.	Sh.	Lib.	Sh.	sterl.
1	1	0	to	1	1
2	1	16	to	1	17
3	2	15	to	3	0
4	3	12	to	3	15
5	4	15	to	5	0
6	7	17	to	8	0
7	15	0	to	15	15
8	22	0	to	25	0
9	30	0	to	34	0
10	42	0	to	45	0
11	60	0	to	—	—
12	75	0	to	—	—
13	112	0	to	120	0
14	187	0	to	220	0
15	330	0	to	380	0
16	450	0	to	—	—
17	700	0	to	735	0
18	1500	0	to	1800	0
19	3500	0	to	4500	0
20	4500	0	to	5620	0

Antwerp Cut.

A Diamond weighing 1 grain, is worth from	Lib.	Sh.	Lib.	Sh.	sterl.
1	0	15	to	0	18
2	1	0	to	1	10
3	2	2	to	2	5
4	3	12	to	3	15
5	6	0	to	6	7
6	10	10	to	11	5
7	13	10	to	15	0
8	18	15	to	22	10
9	24	0	to	26	10
10	33	15	to	—	—
11	37	0	to	40	0
12	55	0	to	58	0
13	112	0	to	130	0
14	247	0	to	—	—
15	315	0	to	—	—
16	900	0	to	970	0
17	2200	0	to	2300	0
18	3500	0	to	4500	0

Mr. Jeffries lays down the following rule for the valuation of diamonds of all weights. He first supposes the value of a rough diamond to be settled at 21 per carat, at a medium; then to find the value of diamonds of greater weights, multiply the square of their weight by 2, and the product is the value required. E.g. To find the value of a rough diamond of two carats, $2 \times 2 = 4$, the square of the weight, which multiplied by 2, gives 8. The true value of a rough diamond of two carats. For finding the value of manufactured diamonds, he supposes half their weight to be lost in the manufacturing of them; and therefore to find their value, we must multiply the square of double their weight by 2, which will give their true value in pounds; thus, to find the value of a wrought diamond weighing two carats, we first find the square of double the weight, viz. $4 \times 4 = 16$, then $16 \times 2 = 32$. So that the true value of a manufactured diamond of two carats is 32l.

By this rule Mr. Jeffries has constructed tables of the price of diamonds from 1 to 100 carats.

According to Mr. Jeffries's rule, that the value of diamonds is in the duplicate ratio of their weights, and that a manufactured diamond of one carat is worth at a medium 8l, the great mogul's diamond must be valued at above 624962l, this being the value of a diamond of 279l carats.

It must be observed, however, that defects in the water, or shape, red or black spots, thiers, and other failings, frequently found in these stones, reduce the price by one third, and sometimes more.

When diamonds are fouled with a yellow or brown colour, it is a common practice among jewellers to put them in a fierce fire, this divests them of their colours, without doing them the least sensible injury. Du-Fay, in Mem. Acad. Paris, 1735.

As to brilliant diamonds of very small cut, the price is always less by one third than that of diamonds of a larger cut, though the weights be the same; the reason is, that the latter show themselves a great deal more when set in their collars, than the former.

DIAMONDS, Specific gravity of. Mr. Boyle has given us the observation of a person much conversant in diamonds, that some of those gems in their rough state were much heavier than others of the same bigness, especially if they were cloudy or foul; and Mr. Boyle mentions one that weighed 8 grains and 15, which being carefully weighed in water, according to the rules of hydrosta-

D I A

tics, proved to an equal bulk of that liquor, as $2\frac{1}{2}$ to 1. So that as far as could be judged by that experiment, a diamond weighs not thrice so much as water; and yet in his table of specific gravities, that of a diamond is said to be to water as 3400 to 1000, that is, as $3\frac{1}{2}$ to 1; and therefore, according to these two accounts, there should be some diamonds whose specific gravity differs nearly 4 from that of others. But this is a much greater difference than can be expected in two bodies of the same species, and indeed on an accurate trial does not prove to be the case in diamonds.

It is certain that there may be some difference in these trials, from the nature and temper of the water used in the experiments; some waters, as that of pumps or wells, being heavier than rain or distilled water; and the heat or coldness of the water may also make some variation: this, however, is much less than might be expected; careful experiments having proved, that the specific gravity of any body will not differ above $\frac{1}{100}$ at most, on account of the difference of the water in quality and temper taken together; whereas the heaviest and lightest of the diamonds in Mr. Boyle's and these experiments differ about one thirty-sixth part, which is about six times as much as $\frac{1}{100}$.

Mr. Ellicott, who made these experiments, has drawn out a table of their several differences, which is done with great care and accuracy, and taking in all the common varieties in diamonds, may serve as a general rule of their mean gravity and differences.

Water	In air.		Specific gravity.
	Grains	Grains	
No 1. A Brazil diamond fine water, and rough coat,	97425	6616	3518
2. Ditto, fine water, rough coat,	8821	6316	3521
3. Ditto, fine bright coat,	10025	7470	3511
4. Ditto, fine bright coat,	9560	6830	3501
5. An East India diamond, pale blue,	26485	18945	3512
6. Ditto, bright yellow,	2333	1671	3524
7. Ditto, very fine water, bright coat,	2066	148	3525
8. Ditto, very bad water, honey-comb coat,	2038	1459	3519
9. Ditto, very hard bluish call,	225	161	3515
10. Ditto, very soft, good water,	22615	162	3525
11. Ditto, a large red fool's diamond,	2548	1823	3514
12. Ditto, soft, bad water,	20525	21140	3521
13. Ditto, soft, brown coat,	26535	1899	3516
14. Ditto, very deep green coat,	2525	1568	3521

The mean specific gravity of the Brazil diamonds appears to be . . . 3513

The mean of the East India diamonds . . . 3519

The mean of both . . . 3517

Therefore, if any thing determinate is to be said, as to the specific gravity of the diamond, it is, that it is to water as 3517 to 1000. Phil. Transact. vol. xliii. for 1745. art. 10. p. 472.

Attempts have been made to produce artificial diamonds, but with no great success.

The *falsified diamonds* made in France, called *temple diamonds*, on account of the temple at Paris, where the best of them are made, fall vastly short of the genuine ones; accordingly they are but little valued, though the confusion thereof is pretty considerable for the habits of the actors on the stage, &c. See PASTES.

DIAMONDS, Cornish, in Natural History. A name given in England to all the species of crystals, which are composed of a column, terminated at each end by a pyramid. The name takes in two genera of crystal, of each of which there are several species. Dr. Hill has determined this to be the true figure of perfect crystal, and accounts all those which are affixed by one end to some solid body, and terminated at the other by a pyramid, to be mutilated or imperfect crystals. The same author, according to the length or thickness of the intermediate column, has divided these bodies into two genera, the first the *macrotelostyla*, the other the *brachytelostyla*. See MACROTOSTYLA and BRACHYTOSTYLA.

DIAMOND is an instrument of considerable use in the glass manufactory, for squaring the large plates, or pieces; and among glaziers for cutting their glass.

These diamonds are differently fitted up. That used for looking-glasses, and other large pieces, is set in an iron ferril two inches long, and a quarter of an inch in diameter. The rest of the cavity of the ferril is filled with melted lead, which keeps the diamond firm in its place. The glaziers have a handle of box, or ebony, fitted into

the

the ferril to hold it by. In the former there is a little piece of box crossing the ferril, in *la m* of a little plane, covered at bottom with a thin copper-plate.

DIAMOND, in *Herbology*, is used to express the black colour in the achievements of noblemen.

Gwillim dislikes the way of blazoning the coats of peers by precious stones, instead of metals or colours. But the English practice allows it. See COLOUR.

DIAMOND-CUTTER. See LAPIDARY.

DIAMOND-GLASS. See GLASS.

DIAMOND-POWDER is of great use for grinding hard substances. And Mr. Boyle observes, that though it be much dearer than emery, yet it makes to great dispatch, and the tools employed last to much longer, as greatly to over-balance the cheapness of the emery.

DIAMORUM, *DIAMORUM*, a composition in pharmacy, of which there are two kinds, *simple*, and *compound*.

DIAMORUM, *Simple*, is the common syrup of mulberries, made of the juice of that fruit, boiled up with sugar. It is good against diseases of the throat, and to stop dysenteries.

There is also a sort of *simple diamorum* made of mulberry juice and honey, otherwise called *mulberry ros*.

DIAMORUM, *Compound*, is made with mulberry juice, verjuice, myrrh, and saffron. It is used to deterge phlegm from the stomach and breast, and to ease respiration.

DIANA, in *Mythology*, the daughter of Jupiter and Latona, and twin sister to Apollo. She is said to have been born first, and to have assisted her mother in the delivery of Apollo. The sufferings of Latona on this occasion, gave Diana an aversion to marriage, though not to gallantry. She is accused of having loved and bestowed her favours on Endymion, Pan, and Priapus. She was the goddess of the woods on earth, Luna in heaven, and Hecate in hell.

The most known character of this goddess is that of her presiding over woods, and delighting in hunting. Accordingly the *Diana venatrix*, or goddess of the chase, is frequently represented in ancient statues, and described by the Roman poets, as running, with her vest shortened and girt about her, and yet flying back with the wind: she is tall of stature; and her face, though so very handsome, is somewhat manly: her legs are bare, well-shap'd, and strong: her feet are sometimes bare, and sometimes adorned with a sort of buskin: she often has her quiver on her shoulder: and sometimes holds a javelin, but more usually her bow in her right hand.

The flames of Diana were frequent in the woods, where she is represented as hunting, bathing, and telling herself after fatigue. Diana has been sometimes represented with three bodies, and hence called the triple, three-headed, and three-bodied *Diana*. Her distinguishing name, under this triple appearance, is Hecate or Trivia; under which character of the infernal Diana she was invoked in enchantments, and represented as a Fury, holding infractions of terror in her hands, and grasping cords, ivories, serpents, or flaming torches. When she is represented as the intelligence that presides over the moon, she appears in a car, drawn by stags, or by dogs, but more commonly by horses of a perfectly white colour, with a lunar crown or crescent on her forehead. Spence's *Polymetis*, p. 100, 102, 104.

She had many temples dedicated to her, of which that at Ephefus was the most celebrated, and esteemed one of the wonders of the world. It was burned by Erostratus, or Eratosthenes, to perpetuate his name by the action, on the day in which Alexander was born, A. M. 3548. Apollo and Diana were names for the sun and moon, and had each of them lances given them, in allusion to the projection of their rays.

DIANA'S TREE, *Arbor Dianæ*. See ARBOR.

DIANDRIA, in *Botany*, the second class of plants, which have hermaphrodite flowers, with two stamina or male parts in each.

The word is formed of the Greek *di*, twice, and *andria*, male. Of this class of plants, which comprehends three orders, viz. the *monogynia*, *dygyna*, and *trigyna*, are the jessamine, phillyrea, olive, rosemary, &c. See *Tak. of Botany*, Class 2.

DIANTHERA, in *Botany*, a genus of the *diandra monogynia* class. The characters are these: the flower hath a permanent empancment of one leaf, which is tubulose, and cut at the top into five equal parts: the flower is of the grinning kind, having one petal with a short tube; the upper lip is reflexed and bifid; the lower is divided into three parts, the middle being the broadest: it hath two short slender laminae adhering to the back of the petal, one of which has a twin summit, the other is a little taller. It hath an oblong germin supporting a slender style of the length of the lamina, crowned by an obtuse stigma. The empancment afterward becomes a cap-

sule with two cells, opening with two valves, which are alternately compressed at the top and bottom, and open with an elasticity, casting a single seed out of each cell. This plant grows naturally in Virginia, and other parts of North America. Linnaeus enumerates two species.

DIANTHON, from *dia* and *anthos*, flower; in *Medicine*, an antidote described by Myresius, from which the *specie dianthos* in the London dispensatory was probably taken. It is thus made:

R Flor. rosar. ʒi. rosar. n. ʒi. rad. glych. ʒi. caryoph. arom. ʒi. rad. nuc. mosch. rad. galangal. cort. cinnamon. rad. zedair. lign. aloes, sem. card. min. sem. anethi, anisi, & macis ʒi. ʒiv. M.

This composition is recommended in the catbary.

DIANTHUS, in *Botany*, a genus of the *diandra digyna* class; the clove July flower, carnation, and pink. The generical characters are these: the flower hath a cylindrical empancment of one leaf, scaly below, with five petals, whose tips are as long as the empancment; but their upper part is broad, plain, and spread open. It hath ten stamina; in the centre is situated an oval germin, which afterward becomes a cylindrical capsule with one cell, opening in four parts at the top, filled with compressed angular seeds. Linnaeus enumerates eighteen and Miller twelve species. See CARNATION, PINK, &c.

DIANUCUM, in *Pharmacy*, a kind of rob, made of the juice of green walnuts, and sugar, boiled together by a moderate fire, to the consistence of honey.

The word is formed from *dian*, and *nuc*, nuts, nut.

It is good to strengthen the stomach, promote sweat, and resist poison.

DIAPALMA, in *Pharmacy*, a desiccative, or drying plaster, said to be so denominated from the wood of the palm-tree, whereof the spatula is to be made, that is to stir it while boiling. It is composed of common oil, hogs fat, and litharge of gold. It is good to dry, resolve, deterge, and cicatrize; and is the plaster most used for wounds and ulcers.

DIAPASMA, a common name for all powders sprinkled on the body, whether as perfumes or otherwise.

The word comes from the Greek *diapasma*, in *aspergers*, to sprinkle.

DIAPASON, from *dia*, by, and *pas*, all, in *Music*, a musical interval, otherwise called *diatona*: so called, because it contains all the possible diversities of sound.

The *diapason* is the first and most perfect of the concords: if considered *simply*, it is but one harmonical interval; though if considered *diatonically*, by tones and semi-tones, it contains seven degrees, viz. three greater tones, two lesser tones, and two greater semi-tones.

The interval of a *diapason*, that is, the proportion of its grave sound to its acute, is as 2 to 1.

The ancients had seven various, schemes, figures, or species of the *diapason*, arising from the various dispositions of the tones and semi-tones in the scale.

The first species of the *diapason*, was from the hypate hypaton to the paramete; or from B to b of our notation. It was called *myxolydian*.

The second, called *lydian*, from the parypate hypaton to the trite diez myxomenon, or from C to c.

The third, called *phrygian*, from the lichanos hypaton to the paranete diezzeugmenon, or from D to d.

The fourth, called *dorian*, from the hypate meson to the netze diezzeugmenon, or from E to e.

The fifth, named *hypolydian*, from the parypate meson to the trite hyperbolicon, or from F to f.

The sixth, called *hyphrygian*, from the lichanos meson to the paranete hyperbolicon, or from G to g.

The seventh, named *hypolydian*, *cymmen*, and *lydian*, from the mese to the netze hyperbolicon, or from the prolammenomenos to the mese, that is, from our a to a, or from A to a. Euclid. *Introd. Harm.* p. 15, seq.

Bacchius, p. 18. edit. Melbon. See DIAGRAM.

DIAPASON, *diatessaron*. The Pythagoreans did not admit this interval as a concordance or concord: for this reason, that its ratio 8 : 3 was neither multiple nor superparticular. But Ptolemy contends for its being a good concord, for this reason, that the *diapason* added to any concord, produces a concord. Aristoxenus herein agrees with him. Vide Wallis's *Append. ad Ptolem.* *Harm.* p. 135.

DIATONOS, among *Musical Instrument-Makers*, is a kind of rule, or scale, whereby they adjust the pipes of their organs, and cut the holes of their flutes, hautboys, &c. in due proportion, for performing the tones, semi-tones, and concords, justly.

A square being divided into eight equal parallelograms, the points wherein a diagonal intersects all these parallelograms, express all the usual intervals in music; and on this principle it is, that the *diapason* is founded.

There is a particular kind of *diapason* for trumpets; serving

ing as a standard, or measure, for the different magnitudes they must have to perform the four parts of music. There is another for *treble*, and *tenors*, showing how far they are to be lengthened, or shortened, to rise or fall from one tone or interval to another.

The bell-founders have likewise a *diapason*, or scale, serving to regulate the fire, thickness, weight, &c. of their bells.

DIAPHRAGM, is also the name of two Rops of an organ, viz. the open and stopped.

DIAPASNDIALEX, in *Music*, a kind of compound concord; whereof there are two sorts: the *greater*, which is in the ratio of 10 to 3; and the *less*, in that of 16 to 5.

DIAPASNDIAFENIT, in *Music*, a compound concordance, in a triple ratio of 9 to 3.

The *diapason* is a symphony made when the voice proceeds from the first to the twelfth tone. The word is properly a term in the Greek music; we should now call it a *trill*.

DIAPASNDIAFESSARON, in *Music*, a compound concord, in the ratio of 8 to 3.

The *diapason* is a symphony wherein the voice proceeds from the first tone to the eleventh. This the moderns would rather call an *eleventh*.

DIAPASNDITONE, in *Music*, a compound concord, in the proportion of 10 to 4, or 5 to 2.

DIAPASNDISEMIDITONE, a compound concord, whose terms are in the proportion of 13 to 5.

DIARESES, *Διαρρηξις*, in *Medicine*, an exuding of blood through the coats of the veins, or arteries, occasioned either by the blood's becoming too much diluted, or attenuated; or by the pores of the vessels becoming too patent, and open.

The word is compounded of *δια*, through, and *ρρηξις*, *Disp.* There are some physicians who deny there can be any such faculty of blood, as that it shall exude through the vessels, without any aperture made therein.

DIAPYCNIA, in *Botany*, a genus of the pentandria monogynia class; the corolla is monopetalous and falved; the calyx has five leaves imbricated with three small ones; the flammies are laid on the tube of the corolla; and the capsule has three cells. There are two species.

DIAPENTE, in the *Acoustics*, an interval making the second of the perfect concords; answering to what in the modern music we more usually call a *perfect fifth*. The word is formed of *δια*, and *πεντε*, five.

The *diapente* is a simple concord; viz. it is considered diatonically, it contains four terms, viz. two greater notes, a lesser note, and a greater lesser-note. The *diapente* is the greater part of the diapason, or octave, harmonically divided. It is produced when the voice passes from its first tone to its fifth.

DIAPENTE is also used, in *Pharmacy*, for a compound of five several drugs, or ingredients.

DIAPENTE, among *Farmers*, a drink made for horses, of gentian, root hithwort, barberries, myrrh, and ivory shavings, of each a like quantity, which are to be pounded separately, and finely forced: this powder to the quantity of two or three spoonfuls, is mixed with a pint and a half of muckdew, or sack, or, for want of either, with strong ale or beer, and given in fevers, the cough, glanders, farsetts, inflammations, yellow, &c. It is said to purify the blood from all foulness, as well as to tell in the overflowing of the gall, working of the spleen, &c.

DIAPER, a sort of linen cloth wrought with flowers and other figures.

DIAPERED, in *Healdy*. See **DIAPER**.

DIAPHANOUS, in *Philosophy*, a thing transparent; or that gives passage to the rays of light; as water, air, glass, &c. fine porcelain, &c. See **TRANSPARENCY**.

The word is formed of *δια*, through, and *φανος*, I flow.

DIAPHANEITY, in the schools, the quality of a transparent body; or that which denominates it such. See **TRANSPARENCY**.

DIAPHENIC, *Διαφηνικόν*, in *Pharmacy*, a soft, purgative electry; thus called from the dates, which make its basis; the palm-tree, whole fruit they are, being called by the Greeks *φαινός*. See **DATY**.

The other ingredients are, pumilus, almonds, turbit, ginger, white-pepper, mace, cinnamon, rice, fennel, carrot-seeds, and honey.

The *diaphenon* purges chiefly scrofulas, and excites the menses. It is also used in dropsies, lethargies, apoplexies, and palsies.

DIAPHONICS, from *δια*, through, and *φωνή*, sound, is sometimes used for the science of restrained sound, as it passes through different media.

DIAPHORESIS, *Διαφωρησις*, from *διαφωρησις*, I diffuse, in *Medicine*, includes all discharges through the skin; both sensible, and insensible; whence *diaphoretic*, &c. See **PERSPICACITY**.

Vol. II. N. 96.

DIAPHORETIC, in *Medicine*, is applied to remedies that promote the expulsion of humours by insensible perspiration.

Diaphoretic is much of the same import as *sudorific*, except that the latter promotes sensible, and the former insensible perspiration. Their only difference, therefore, is in the degree of activity.

DIAPHORETIC anatomy, or *mineral diaphoresis*, is a preparation of anatomy, the process whereof see under **ANTIMONY**.

DIAPHRAGM, *Διαφραγμα*, in *Anatomy*, a part, popularly called the *midriff*, and by anatomists, *septum transversum*. It is a nervous muscle, separating the breast, or thorax, from the abdomen, or lower venter; and serving as a partition between the natural, and the vital parts as they are called.

It was *Philo*, as *Galen* informs us, that first called it *diaphragma*, from the verb *διαφραγναι*, to separate, or to divide. Till his time it had been called *σπλην*, and *diaphragma*, from a notion, that an inflammation of this part produced phreny; which is not at all warranted by experience, no more than that other tradition, that a transverse section of the *diaphragm* with a sword, causes the patient to die laughing.

Its figure is round, resembling a cylinder, or hemisphere. It is a double and digastric muscle, consisting of two circles, which are both muscular; of two arteries; and two veins, called *diaphragm* and several branches of nerves. The first, or upper circle, called the *great muscle* of the *diaphragm*, is fleshy in its circumference, and tendinous and aponeurotic in the middle; it arises from the sternum, and the ends of the last ribs, by radiated fibres; the second, or inferior, called the *small muscle* of the *diaphragm*, is thicker than the other, of its extent, and of an oblong form; it comes from the ventricle of the lungs by two tendons, called *costae*. The upper is covered at the top with a membrane derived from the *pleura*; and the lower is lined at bottom with another from the *peritoneum*.

Its situation is oblique, being extended from the *cardiophrenic*, by the extremities of the ribs, to the region of the lungs. It is placed in the tendinous part with a round opening for the passage of the *vena cava*, which being incapable of contraction, occasions no interruption to the circulation; and in its fleshy part for the *esophagus*, and with another forked opening, partly fleshy and partly tendinous, for the *arteria* and between the productions of the inferior circle pass the *arteria*, which lies in the interstice between the two *costae*, thoracic duct, and *vena cava*. In its natural disposition it is convex on the upper side towards the breast, and concave on the lower towards the belly. Hence it has two motions: the one of contraction, the other of relaxation.

By the contraction, or swelling of the fibres, the *diaphragm* becomes flat on each side; the consequence of which is, that the cavity of the breast is enlarged, to give liberty for the lungs to receive the air in inspiration; and the cavity of the abdomen is lessened, and, consequently, the stomach and intestines pressed, for the distribution of the chyle. In its relaxation, whereby it resumes its natural situation, the cavity of the breast is diminished, and the lungs pressed for the expulsion of the air in expiration.

On the *diaphragm*, also, in great measure, depend the actions of coughing, sneezing, yawning, laughing, the hiccup, &c. between which motions there is some connexion caused by the communication of the nerves of different parts, which meet in the *diaphragm*.

Dr. Hooke observes, that an animal may be kept alive, without thorax, or *diaphragm*, by blowing air into the lungs with a bellows; of which he had made the experiment.

Mr. Senac has given us a new description of the structure of the *diaphragm*, with remarks on the action of this muscle. See *Mem. Acad. Science*. 1720.

DIAPHRAGM is used for the *septum transversum*. See **SEPTUM TRANSVERSUM**.

DIAPHRAGM is also a general name, given to all partitions, or separations between two parts of a thing; as the little perforated partitions in the tubes of long telescopes.

DIAPHRAGMATIC, is applied to the arteries, veins, and nerves, distributed through the *diaphragm*. They are also called *pleuric*, or *phrenic*.

DIAPHTHORA, from *διαφθορα*, to corrupt, is used by *Galen* and *Boerhaave* to denote the corruption of the aliments in the stomach, and by *Hippocrates* for the corruption of the fœtus in the womb, and abortion.

DIAPHORESIS, *Διαφωρησις*, in *Medicine*, is used to express the insatiation, or uncertainty of the feaver.

We have an example in *Homer*, where *Ulysses* going to relax his sufferings to *Alecinus*, begins thus:

Τεμπέρας, καὶ δ' ἄρ' ἔστιν, καὶ δ' ἄρ' ἔστιν ἄλγος?

Quid primam, quid deinde, quid postremo aliquid?

This

This figure is most naturally placed in the exordium or introduction to a discourse. See DOWLING.

DIAPRE', or DIAPYCNOS, in *Astronomy*, a dividing of a field into planes, or compartments, in the manner of fret-work, and filling it with variety of figures.

This chiefly obtains on borders, which are *scaped*, or
frayed over, and the iron charged with things proper to
borderment, as in *Tab. Heut. de. 18.*

DIAPHRONUM, in Pharmacy, a soft, purgative electary, thus called from the pulp of Damascus prunes, which make up the mass.

with their feet naked, are usually attended afterwards with a simple decoction.

trachile force of the heart. He has found that respiration has an effect upon the heart in this sense which had not been understood before. The systole being the proper motion of the heart, a state of contraction by means of that systole must needs be its natural state, and consequently no motion of relaxation natural, and without external violence it could have no effect at all.

This will appear more plain, if we consider the circumference of the heart, and its motion as a muscle, with respect to other muscles. That contraction is the proper action and natural state of all muscles, is evident from experience as well as from reason; for if any muscle be freed from the power of its antagonists, it is immediately contracted, and is not, by any action of the will or spirit, to be reduced to a state of relaxation; thus, if the *musculus latissimus* of any joint be divided, the *extensor* of that joint, the *opponens* muscles in the *finger*, being freed from the contrary action of their antagonists, will exert themselves; the joint will be extended without the consent of the will, and it will continue in that position; and, on the other hand, if the *extensors* are divided, the *contractors* will of themselves exert their force, and the limb will be contracted without the consent of the will, and it will continue in this posture. It is very evident from all this, that the muscles of the human body have no relaxative power of their own, but that all power of this kind in them is derived from the action of their antagonists, by which they are balanced; thus likewise the *flexors* of the *groin*, *anus*, and *anus*, having no proper antagonists, are always in a state of contraction, and suffer nothing to pass through them, but what is forced by the action of other stronger muscles; which, though not properly antagonists to these, yet on all necessary occasions, perform the office of such.

The heart is a solitary muscle; it has no antagonists, and is not under the direction of the will; as it performs also its voluntary motion, from all things approaches more to the nature of the *larynx* muscles, than to any kind of *limbs*; thus, in its constant action of contraction and dilatation, it differs exceedingly from all the muscles of the body. This reciprocal motion of the heart has given the learned abundance of trouble, who finding nothing peculiar in the structure which should excite it, nor any antagonists whose relaxation should produce it, have been extremely perplexed to find out the cause of it.

Lower having proved the *heart* muscle, and established the manner of its muscular motion, takes notice of no farther assistance that it receives for the performing this than what it has from the brain, by means of the eighth pair of nerves. Borelli, in his *Animal Mechanica*, computes the motive power of the heart to be equal to, at least, that of a weight of three thousand pounds. The obstacles to the motion of the blood, through the arteries, he estimates equivalent to one hundred and eighty thousand pounds, which is sixty times as much as he takes the force of the heart at; then deducting forty-five thousand pounds, for the resistances help of the muscular distension of the arteries, he leaves the heart, with the full force of three thousand pounds, to overcome the resistance of a hundred and thirty-five thousand pounds; thus, with one, to remove forty-five. This hypothesis could be easily himself with attention to the *energy* of position; but, had he proceeded in his calculation by the ratio, which he allows to contain constantly a quantity of blood quadruple to the contents of the arteries, and to which this energy of percussion does not either reach at all, or but very imperfectly, he might possibly have found a necessity of some other expedient, or remove to insupportable a similarity.

But not to insist regularly on the exactness of this computation, we may allow a much greater defect on them would be judicious, without lessening the difficulty. Dr. Lower, notwithstanding the care and sagacity with which he examined this subject, seems to have overlooked something of very great moment, in the explanation of the action of the heart; for, though it should be granted, that the muscular fibres of the heart acted by the nerves, are the immediate instruments of its systole or contraction, yet it must not be denied that the intercostal muscles and diaphragm are of great service, to aid and facilitate this contraction, by opening a passage for the blood through the lungs, which descent would be an insupportable obstacle, rather, as the lungs promote the motion of the heart in that way only, but the manner in which they assist the heart in its contraction, will appear manifestly, if we consider the different posture, situation, and capacity of the blood vessels of the lungs in the interval times of elevation and depression of the chest.

The pulmonary artery rises from the right ventricle of the heart, and runs in one trunk, till it comes to the *apex* artery, where it is divided, and sends a branch

along with each division of the *apex artery*; according to all the minutest subdivisions of which, it is also subdivided, accompanying all the *trunks* in their passage through the lungs.

The pulmonary vein, which empties itself into the left ventricle of the heart, spreads itself on the *apex artery* and *trunks*, and continues its progress in the same manner in which the artery does. The necessary consequence of this disposition is, that this artery and vein being co-extended with, and fastened to *trunks*, it must needs follow each alteration of position of the *trunks*, while the ribs are in a state of depression, whether before to contract with the external air, or after the intercostal cartilages of the *trunks* link into one another, and by that means their dimensions are exceedingly contracted; its conformity to this motion of the *trunks*, the pulmonary artery and vein must likewise follow by means of their muscular coats, contract themselves to the same dimensions, or be in a state of contraction, which is much less probable.

On the other hand, when the ribs are elevated, and the diaphragm bears downwards, the air rushing into the lungs, thrusts out the cartilages of the ribs, and dilates the branches of the *trunks*; and by these, extends and dilates the lateral distensions of the pulmonary artery and veins, and thereby lengthens and enlarges their cavities. This enlargement of their cavities is very considerable, not only upon the face of the medium which they receive in length thereby, but also on account of their distension for width; when the ribs are depressed, and the lungs become, the blood vessels are not only contracted, but their branches, which are exceedingly numerous, approach one another, and lie in juxtaposition, by which their cavities are very much compressed and flattened; when the ribs are elevated, and the lungs expand with air, not only the fibres, by which their coats in the opposite state were contracted, are extended, but their innumerable ramifications, which lying before in their almost contiguous to one another, compressed each other, making an acute angle at their junctures, are dilated and separated from each other, and make an obtuse one, whereby their channels are widened.

That a passage is opened for the blood from the right ventricle of the heart to the left, through the lungs, to which it could not otherwise pass; and the opposition, which the blood contained in that ventricle must otherwise have had made by its contraction, is taken off, and the systole thereby facilitated; nor is this all, for the *apex* being caused, as it is continually and circumstantially the case, by the force of the blood rushing into the ventricle, this augmentation and extension of the pulmonary artery is a sort of check or counterpoise to it, and prevents an embolism towards two contrary directions at once, which would necessarily frustrate the force for the heart being a spring and contractile body, whose proper action, which is contraction, depends upon the influx of arterial fluids into its fibres and substance, and containing before a fluid in its interior, or from exterior, in one of the ends of the artery, the action of the vessel must be a great variety depending on a spring, whose extension is impeded by water, the contraction or expansion of the channels of the artery, answering to the drawing or the pushing of the contracting motion of the muscle of the heart, and in the pressure of the atmosphere on the surface of the water, the one making way for the fluid, and the other forcing it to flow where the resistance is least. In this state we may allow a sort of attraction to the pulmonary artery, depending wholly upon the action of the intercostal muscles, and diaphragm, which we must therefore conclude to be very serviceable and instrumental in promoting the systole of the heart. Phil. Trans. N° 281, p. 1222. See HEART.

It has long been known, that the *apex* artery bears a systole and *apex*, exactly corresponding to those of the heart, but its cause was not so well known. Dr. Ridley, in the *Philosophical Transactions*, vol. x. p. 169, has discovered a hole in the upper part of the *apex* of a dog, and perceived the alternate vibrations of the *apex* and *trunk*, continuing the hole to the heart, he found both by his eye, and even when laid by touch, very sensible, that there was a hole in the *apex* and *trunk* of the heart. At the same time, in 1723, made several experiments with dogs, both living and dead, in order to investigate the cause of this motion of the heart, from which he inferred that the true cause is the reflux of the blood towards the heart, and that this reflux is owing to the pressure of the lungs on the veins of the heart, in respiration. Ibid. See BRAIN, and DIAHRON.

DIAPHRAGM, in Geometry, a figure whereby a syllable naturally short is made long.

Thus

Thus it is that Virgil begins a *verse* with the word *Italis*, the first syllable whereof is naturally short.

DIATYLE, from *δια*, and *τυλος*, a pillar, in the *Ancient Architecture*, an edifice, where the columns stand at such a distance from one another, that three diameters, or six modules, are allowed for the intercolumniation. See *Tab. Archit. fig. 40. D.* in the plan of the Basilic.

DIASERMUS, *Διασέρμης*, from *δια* and *σέρμω*, I draw, in *Rhetoric*, a figure whereby we shortly answer, or rather evade, a thing which it would be tedious to reply to in form.

E. g. *What matters it to reply to an argument foreign to the purpose?*

DIATESARON, in *Pharmacy*, a sort of theriaca, thus called, because it consisted of four ingredients, which are roots of aristolochia and gentian, bay-berries and myrrh.

The word is Greek, compounded of *δια*, and *σαρσάρω*, fear, q. d. a compulsion of fear drug.

It is also called *theriaca pauperum*, because made at a very easy expense, and in a short time. It is good against stings of venomous beasts, epilepsies, convulsions, colics, to strengthen the stomach, and promote the menses.

DIATESARON, in the *Ancient Music*, a concord, or harmonical interval, composed of one greater tone, one lesser, and one greater semi-tone; its proportion being as 4 to 3.

In the modern music, it is called a *perfect fourth*.

Many musical writers have rejected the *diatesaron* from the class of consonances. Others have retained it as a secondary or imperfect concord; urging that it is only a concord when the harmony consists of two parts, but not by itself; and that if it were a perfect consonance, the replicate of it would be a consonance likewise; whereas the ear can hardly endure it. Thus they say, whenever a found is a perfect consonance with its unison, the replicate of that found will also be a consonance, as is the case with the diapente and diapason, whose replicates, viz. the 15th and the 12th, which are the diapason and diapente compounded, are not less grateful to the ear than the radical sounds themselves: but the diapason and diatesaron compounded in the 11th, do not make a consonance. See Hawkins's *Hist. Mus.* vol. ii. p. 192. and vol. iii. p. 134.

DIA THESIS, from *δια*, and *thesis*, I dispose, a term used by some writers in the same sense with constitution; and by others for a disposition of the blood to a faulty state.

DIATONIC, from *δια* and *τῶν*, tone, an epithet given to the common music, as it proceeds by tones, or degrees, both ascending and descending.

Authors divide the genera or kinds of music into *diatonic*, *chromatic*, and *cathartonic*.

The *diatonic* genus was by the ancients divided into two species, the *major*, and the *minor*. The last is in daily practice. It is commonly said to consist of two tones and a semi-tone; but, to speak exactly, it consists of a semi-tone major, a tone minor, and a tone major.

We find it accurately defined by Didymus, in Ptolemy's *Harmonics*, published by Dr. Wallis. Vide Wallis, *Opera*, vol. iii. p. 92. The numbers by which Didymus expresses its intervals, are, $\frac{2}{1} \times \frac{3}{2} \times \frac{4}{3} = 2$. Ptolemy, indeed, makes the *diatonic interval* to be expressed by $\frac{1}{2} \times \frac{2}{1} \times \frac{3}{2} = 1\frac{1}{2}$; but it is plain, this is only transposing the tones major and minor, which makes no essential difference, nor is it sufficient to constitute a new species. But the first of the before mentioned species, the *diatonic minor*, has not, till lately, been accurately defined by any author. Its component intervals, according to Dr. Pepusch, are, the semi-tone major, an interval composed of two semi-tones minor, and the complement of these two to the fourth; which complement is equal to a tone major, and an enharmonic dieza.

Besides the two species of the *diatonic* mentioned by Aristoxenus and Euclid, Ptolemy, and other ancient musicians, have left us several different *diatonic* divisions of the tetrachord; such are the *diatonic* of Archytas, of Eratosthenes, and of Didymus, which last agrees perfectly with the truth of musical proportions. Ptolemy himself gives us no less than five different *diatonic* by the names of *major*, *minor*, *diatonic*, *intense*, *equable*. See *GENUS*.

But, except one (the *intense*), they are all inconsistent with the true theory of music, which admits of no numbers, or proportions, but 2, 3, and 5, and such as arise from these primes. Indeed, Ptolemy's tetrachords are so mis-tuned, that Salinus has charged him with having had no ear. Vide Phil. Trans. N° 481.

Diatonic music only allows of three degrees; the greater and lesser tone, and the greater semi-tone.

Vol. II. N° 97.

Hence *diatonic* music appears the most natural, and of consequence is the most ancient.

In the *diatonic* music there is a tone between every two notes, except between *mi* and *fa*, and *la* and *si*, where there is only a greater semi-tone.

DIATONUM, *Διατόνιον*, in the *Ancient Music*, is used for the *diatonic genus*. See *DIATONIC*.

DIATRÆTA, a word used by Pliny, and other of the ancient Romans, to express a sort of cups and vases, which were of great value, and only seen at the tables of the great. They were pellucid and colourless, and cut into various forms, and were often engraven upon with figures expressive of the deeds of honour of the family who possessed them. The best *diatræta* were made of pure crystal of the rock, and the working of them rendered them very expensive; but afterwards they were made of common white glass, and sunk greatly in their price and value. The ancients were very nice in their distinctions of the several kinds of crystal. They termed the purest and finest of all *acutatum*, and the others, which were subject to blemishes and foulness of several kinds, they called by names expressive of them. There was nothing they so much feared in the pieces they selected for this work, as what they called an *over-hardness*, that is, a brittleness, which made the vessel often fly under the engraver's tool, after it had been formed into shape at a great expense; for this reason they were cautious of using the very brightest and clearest masses; for they often found those forced best, which had some of those flaws which we call hairs in them. These they thought the toughest pieces of crystal, and these flaws they easily concealed among the strokes of their work. See *NUBES* and *SAL*.

DIATRAGACANTH, in *Pharmacy*, is a name applied to certain powders, whereof gum tragacanth is the basis. There are two kinds, *cold* and *hot*.

Powder of *cold diatrachanth* is composed of the gums tragacanth and Arabic, liquorice, starch, white poppy-seed, and the four great cold seeds. It is good to thicken and soften the too sharp, and subtle ferous humours falling on the breast, to allay coughs, and to promote spitting.

Powder of *hot diatrachanth* is composed of gum tragacanth, cinnamon, hyssop, almonds, linseed, fenugreek, liquorice, and ginger. It is good against asthma, to promote expectoration, strengthen the stomach, and assist digestion.

DIATRIDE, from *δια*, and *τρις*, I delay, denotes a continued *diatonic*.

DIATYPOSIS, *Διατύπωσις*, in *Rhetoric*, the lively description of a thing, setting it, as it were, before the eyes of the audience. Thus Cicero, *lib. vi. Ver. Jpe inflammationis, febris, & furor, in forma veni, & delicta oculis, ut res esse credulas emittat, &c.*

DIAGOPHRAGMA, in *Natural History*, a genus of *septa*, whose septa are of spar, with an admixture of crystal, which being sometimes also mixed among the matter of the tail, renders the whole more bright and glossy. See *SEPTARIA*.

Of this genus we have the following species; 1. The ferruginous red *diagophragma*, with brownish yellow partitions. 2. The brownish yellow *diagophragma*, with whitish partitions. 3. The bluish white *diagophragma*, with straw-coloured partitions. Vide Hill, *Hist. Foss.* p. 322.

DIALUSION, from *δια*, and *λύω*, I dissolve, in *Antiquity*, a designation given to a performance on the ancient flute with the flute alone.

DIALODROMI, *Διαλοδομίαι*, from *δυναμις*, and *δρομή*, course, in *Antiquity*, those racers who turned round the meta, or goal, and finished their course at the career, or place of starting. The *diastrophos* always took a short breathing or rest, when they arrived at the meta, before they set out again for the career.

DIATULOS, from *δια*, twice, and *τύλος*, station, in *Antiquity*, the name of a particular kind of race, wherein the racers always returned to the place from whence they started, and were called *DIATULODROMI*.

DIATULOS is also used to signify a distance of two stadia. *DIATYLECTIC*, from *δια* and *τυκτώ*, I adjust, or adjust, in the *Ancient Greek Music*, was that which disjoined two fourths, one on each side of it, and which, being joined to either, made a fifth.

Thus in their music was from *mi* to *perimeli*; that is, in ours, from A to B; supposing *mi* to stand in B *sub mi*. They allowed to this *diatylactic* tone, which is our tone major or *la*, *mi*, the proportion of 9 to 8, as being the unalterable difference of diapente and diatessaron.

DIBBLE, from *diffid*, Da, a sharp point, among Gardeners, the name of the setting-Rick, or tool, wherewith they set plants; ordinarily made of the handle of an old spade.

DICA, in *Law*, a tally for accounts, by the number of tallies, cuts, or notches.

DICE, among *Gamblers*, certain cubical pieces of bone or ivory, marked with dots on each of their faces, from one to six, according to the number of their sides.

Sharpeners have several ways of falsifying dice: 1. by sticking a hog's bristle into them, so as to make them run high or low as they please; 2. by drilling and loading them with quicksilver, which trick is discovered by holding them gently between two diagonal corners; when, if false, the heavy side will turn always downwards; 3. by filing and rounding them. But all these methods fall far short of the arts of the dice-makers, some of whom are so dextrous, that sharpeners will give any money for such dice.

Dice pay a large *STAMP*-duty and are prohibited to be imported.

DICK *maris*, in *Hydrometry*, see *MARLE*.

DICERATION, in the *Writers of Medicine*, a name given to a collyrium mentioned by Celsus, and thus named from *dicere*, a burn, burnt hawthorn being a principal ingredient in it.

DICHOREUS, in *Poetry*, the foot of a Latin verse consisting of four syllables; of which the first is long, the next short, the third long, and the last short. It is a double *choreus*, as *simpliciter*.

DICHOTOMY, *bisectio*, a term used by astronomers for that phasis, or appearance of the moon, wherein she is bisected, or shews just half her disk, or circle; or when she is in the beginning of her first and last quarter. The word is Greek, formed of *διχοτομω*, I bisect, or cut into two; of *δύο*, twice, and *τομή*, I cut.

The time of the moon's *dichotomy* is of considerable use in fixing the sun's distance from the earth. But it is very difficult to fix the precise moment when the moon is bisected, or in her true *dichotomy*. Observation informs us, that when she is thirty minutes distant from the quadratures, she appears bisected; but she appears too in the quadratures themselves, and some time afterwards, as Ricciolus acknowledges in his *Almagest*. So that she appears *dichotomized* at least for the space of a whole hour: in which time any moment may be taken for the true point of the *dichotomy*, as well as any other. But the infinite number of moments of time give an infinite diversity of distances. The moment in which the true *dichotomy* happens being thus uncertain, but it being granted, that it happens before the quadrature; Ricciolus takes the middle point between the quadrature, and the time when it is first dubious, whether the moon be *dichotomized*, or not, for the true *dichotomy*. Keil.

DICHOTOMY, in *Botany*, a term used to express that division of the branches which we see in millet, and in the greater part of the sea-tufts, in which each branch is divided into two.

DICHOPTHYLLUM, in *Botany*, the name by which *Dillenius*, and several others, call the *hydrastatisphyllum* of *Vallant*, and some other writers; a genus of plants characterized by *Linnaeus* in his *Genera Plantarum* under the name of *GERATOPHYLLUM*.

DICKER, or *DICER*, *Diera*, in our *Old Writers*, a quantity of leather consisting of ten hides.

Some derive the word from the Greek *δέκα*, ten. We find the word *diera* applied to other things besides leather; thus, *Cicero* *Glaucostris reddidit xxvi. diceras ferri*, which is interpreted thirty-six *diceras* of iron, ten bars to the *diera*. *Gales's Hist. Brit.* 766. ap. *Blount*.

DICROTUS, in *Natural History*, a word used by the ancients to express the deer or stag when in its third year's growth. It was called *nicus* by the ancient Greeks in the first year, *pantlus* in the second, *dierata* in the third, and in the fourth and all its life afterwards *icrestus*.

DICROTUS, from *δύο*, twice, and *κρότος*, I strike, in the *Medical Writers of the Ancients*, the epithet given to a peculiar sort of pulse, which Dr. *Nihil* calls very properly in English the rebounding pulse. In this kind of pulse the artery beats as it were double; and is esteemed a certain sign of a future critical hemorrhage by the *wise*. When the rebounding pulse is perceived at about every thirtieth pulsation, the hemorrhage usually follows in about four days after; when it recurs at every sixteenth pulsation the hemorrhage generally follows in three days; when at every eighth pulsation, it is to be expected in two days and a half; and, finally, when it recurs at every fourth, third, or second pulsation, or is continual in every one, the hemorrhage is to be expected within four and twenty hours. Sometimes nature runs regularly through all the before mentioned progressions of this critical pulse from its first appearance at every thirtieth stroke, to the single pulsation; and in this case the hemorrhage is seen gradually approaching, and happens regularly as expected; but sometimes the hastens or delays it; and then the pulse fluctuating in its indications, it cannot be judged of with any certainty. When the ar-

tery rebounds upon the finger with great celerity, and very briskly follows the first stroke, the hemorrhage is just at hand, and will appear on the patient's blowing his nose.

The quantity of the hemorrhage may be guessed from the strength of the rebound in the pulse, and as the blood discharges itself, this symptom in the pulse gradually goes off; and if after the hemorrhage it should be perceived again, it is a sign of another crisis of the same kind. Finally, when the rebounding of the artery is more evident in one wrist than in the other, the blood usually flows in the greatest violence from that side of the nose, or that nostril which is on the same side with the hand in the artery of which the rebounding has been most violent.

DICTAMNUS, in *Botany*. See *DITTANY*.

DICTATE, *Dictamen*, in the *Schools*, a suggestion, motion, or sentiment of a man's CONSCIENCE. A good action becomes evil, if done contrary to the dictates of one's own conscience.

DICTATE, *Dictata*, is likewise used in the *Schools* for a lesson, or exercise, wherein the master reading, or speaking something, the scholars take it down in writing after him. Here the act of the master is likewise called *dictating*.

DICTATOR, a Roman magistrate, created by the senate, or people, on some extraordinary and eminent occasion, to command, with sovereign authority, for a certain time, ordinarily limited to six months, though the office was sometimes continued to twelve.

Recourse was never had to such an officer but in dangerous and difficult times; as in sudden wars, popular factions, &c. He had absolute and monarchical power while his dictatorship lasted: and some will even have it, his power went beyond that of the kings. He was arbiter of peace and war, and had command of life and death, without any appeals lying to the people. Twenty-four axes were borne before him, whereas only twelve before the consuls.

The origin of this office was unknown even in *Livy's* time: though some ancient authors speak of *T. Larginus Flavius* as the first dictator, who was appointed in the year of Rome 259. *Sed nec anno, nec quibus consulibus: nec quis primum dictator creatus sit, fortis casus: apud veteres tamen auctoritas, L. Lartium dictatorem primum, Sp. Cassium magistrum equitum creatorem vocem. Consulibus legere. Liv. lib. ii.*

Sylla was the first perpetual dictator, and Caesar the next. After Caesar, there were no more dictators. The first dictator chosen from among the people was *Marcus Rutilius*, in 379.

Diogenes *Halicarnassensis* derives the word *dictator*, because they ordained or appointed what they pleased. But *Varro* will have the word taken hence, that the consul named him, which the Latins call *dicere*, lib. iv. De *Lingua Latina*. *Dictator quod a consule dicebatur, cuius dicta audientes omnes obtemperant.*

DICTION, the phrase, elocution, or style of a writer, or speaker.

The *dictum* or language of an orator should be pure, proper to the subject, rich without affectation, strong and clear without dryness, and suitable to the person, time, place, and audience.

The *dictum* of tragedy is accounted the fourth of the essential parts thereof: it is of the least importance of any; yet must peculiar care be taken herein to make every passion speak its proper language.

DICTIONARY, a collection, or catalogue of all the words of a language, or art, with their significations: ranged in the order of the alphabet.

What the Latins, and we after them, call *dictionary*, the Greeks call *lexicon*.

For the proper character, nature, office, &c. of a dictionary, see the preface to this work. See also *VOCABULARY*.

The most ancient dictionaries for the Latin tongue, are, that called *Papias*, compiled by *Solemnus*, abbot of *St. Gall*, bishop of *Constance*, who lived about the year 1259; another made in 1450, called *Gemma Vocabularum*; a third in 1523, called *Gemma Gemmarum*; and a fourth by *Dionysius Nether*, a Cordelier.

The most celebrated old Latin dictionary is that of *Ambrose Calepinus*, a hermit of *St. Augustine* at *Bergamo*, and son of the count of *Calepin*. *Conrad Gesner* is said to have augmented this with four thousand words. *Paulus Manutius* increased it still more, and *Palisart* after him; and yet *Matthias Martinus* made two volumes of their omissions.

There is another noted Latin dictionary of *Crispinus*: to say nothing of *Cowper*, *Holyoke*, *Gouldman*, *Littleton*, *Cole*, *Ainsworth*, and many others of less consideration.

For the Greek, we have those of *Henry Stevens* and *Scopula*.

Scapula, Schrevelius, and Hedericus: for the Spanish, those of Covarruvias, and Delpino: for the Italian, those of the Academy della Crusca, Veneroni, and Boretti: for the French, those of Nicod, Fa. Monet, Fa. Gaudin, Furetiere, Richelet, Treverous, that of the French Academy, Boyer, and Chambaud: for the English, we had scarce any worth the mentioning (unless, perhaps, those of Lloyd, Phillips, Kerley, and Bailey) before the publication of that very complete and accurate one by Johnson.

Janus has a *dictionary*, or alphabet, of the Gothic, Runic, and Anglo-Saxon. There is another in the Malayan, which is a dead language, famous throughout the East-Indies, where it stands instead of the Latin among us.

There are also historical and geographical *dictionaries*: as that of Charles Stephens, which is translated into French, and augmented by Moreri: another of Hofmann, printed at Basil in 1677, in two volumes folio; which were followed by a continuation of as many volumes, in 1683: another of Mr. Bayle, under the title of Historical and Critical *Dictionary*, first printed at Rotterdam in 1697, in two large volumes, now making five in English: a Philosophical *dictionary*, by Mr. Chauvin de Boilly: besides several law *dictionaries*, as Jacob's; physical *dictionaries*, as James's: family *dictionaries*, *dictionaries* of arts, as the Encyclopædia, &c. of commerce, as Savary's by Folschewitz, &c.

DICTORES, in our *Old Writers*, is used for an arbitrator.

DICTUM, in our *Old Writers*, is used for an arbitration or award.

DICTUM de Kinsworth, an edit or award between King Henry III. and those barons who had been in arms against him. It was so called because made at Kinsworth castle in Warwickshire, anno 5. Hen. III. It contained a composition of five years rent for the lands of those who had forfeited them in that rebellion.

DICTYNNIA, or **DICTYNNIA**, in *Mythology*, were feasts celebrated at Lacedæmon and in Crete, in honour of Diana *Dictynna* or *Dictynna*, or of a nymph taken for her, who, having plunged herself into the sea, to escape the passion of Minos, was caught in a fisherman's net or *sauro*, whence the name.

DIDACTIC, in the *Schools*, signifies the manner of speaking, or writing, adapted to teach or explain the nature of things.

The word is formed from the Greek *didaxus*, *doctus*, I teach.

There are many words that are only used in the *didactic*, and dogmatic way: and there are many works, ancient and modern, both in prose and verse, written after this method: such are the *Georgics* of Virgil, Lucian's poem *De Rerum Natura*, and Pope's *Essays on Criticism* and on *Man*, &c. &c.

DIDAPER, in *Ornithology*. See *Don-did*.

DIDAR, among the Arabian authors, the name of the elm.

DIDELPHIS, the name by which Linnaeus calls the animal called philander by other writers. This creature, in that author's system of zoology, is also a distinct genus of animals, of the order of *feras*, and class of *mammalia*: the characters of which are, that they have ten upper fore-teeth, and eight lower, with the two intermediate very short; the laminae are long, and the molars denticulated: they have also a small bag or pouch under the belly. See *OROSIUM*.

DIDRACHM, from *duo*, double, and *drachma*. See *DRACHM*.

DIDYMI, *didymi*, the same with *gemelli*, or *twins*.

DIDYNAMIA, in *Botany*, the fourteenth class of plants, whose flowers have two of their male parts or stamina of greater efficacy in the action of impregnation of the seeds than the other two: they are known by the efficacious stamina being always much longer than the others. See *Talk of Botany*, Class 14.

The word is formed of the Greek *dyo*, twice, and *namus*, power or efficacy. Of this class of plants are baum, thyme, lavender, basil, &c.

Linnaeus divides this class of plants into two orders: the first the *gynopermia*, and the second the *angiosperma*. The first of these comprehends the labiate plants of Tournefort, and the vesiculate plants of Mr. Ray's method; and the other, the perispermous plants of Tournefort.

The *gynopermia*, or vesiculate plants, are distinguished from the rest by having the seeds four in number, excepting phyma, which is monospermous; and standing naked in the cup: and the stigma divided into two segments, the lower of which is crooked. This order contains thirty-four genera, distinguished into such as have the calyx quinquelobed and nearly equal, of which there are twenty; and such as have the calyx bilabiate, of which there are fourteen.

THE ANGIOSPERMIA, or perispermous plants, are distinguished from the others, by always having a seed-vessel of some form, though very various; and by the stigma being obtuse and various.

Of the first kind, or *gynopermia*, are the galopha and ballota, with the like; and of the second kind, or *angiosperma*, are the antirrhinum, &c.

DIE. See *DYE*.

DIEBEL, in *Ichthyology*, a name given by Kentman and others to the chub or capito. It is properly a species of the cyprinus. See *CAPITO* and *CYPRINUS*.

DIELCYSTINDA, among the *Antients*, a kind of exercise performed by boys, who being divided into two parties or sides, each endeavoured to draw the other over to their side, and the party which prevailed gained the victory.

DIEH *clausit extremum*, a writ issued out of chancery to the executor of the county, upon the death of any of the king's tenants in *capite*, to enquire by a jury of what lands he died seised, and of what value, and who was the next heir to him.

DIEMERIS, in the *Ancient Medicine*, a word used sometimes alone, and sometimes joined with the word *phorbia*. It expressed a sort of bandage, used by the ancients, to tie up the lower lip in playing on the pipe. The other kind of *phorbia* consisted only of one perpendicular piece, which went down the cheek, and one transverse one which covered the whole mouth, but had a hole cut into it to admit the mouth-piece of the pipe. See *PIPERNA*.

DIER. See *DYER*.

DIERVILLA, in *Botany*. Its characters are these: the flower is of one leaf, cut into five parts at the top; it hath five stamina, which are equal with the petals; at the bottom of the flower is situated an oval germen, which afterward becomes a pyramidal berry divided into four cells, which contain small round seeds. There is but one known species, which is a native of the northern parts of America.

This, in the Linnaean system, is a species of the *LONICERA*.

DIES. See *DAY*.

DIES, in *Common Law*. There are two kinds of *days*: *juridici*, & *non juridici*.

Dies juridici, or *fasti*, are all days wherein justice is administered in court.

Dies non juridici, or *nefasti*, are all Sundays in the year: and in Easter term, the feast of the Ascension of our Lord: in Trinity term, the Nativity of St. John the Baptist: in Michaelmas term, the feast of All Saints, and All Souls: and in Hilary term, the Purification of the Blessed Virgin.

The same distinction holds not only as to legal proceedings in court, &c. but also as to contracts.

Dies, in some *Ancient Authors*, is also used for daily provision. *Et reddidit dominum diem meum, q. d. as much honey as served the king's family half a day.*

Dies datus, is a day, or time of respite given to the tenant, or defendant, by the court.

Dies Marchie, was a day of congress, or meeting of the English and Scotch, appointed annually to be held on the marches or borders, to adjust all differences between them, and preserve the articles of peace.

DIESIS, from *diuo*, I divide, in *Music*, a division of a tone, lesser than a semi-tone; or an interval consisting of a lesser, or imperfect semi-tone.

The *diesis* is the smallest, and softest change, or inflexion, of the voice imaginable. It is also called a *semita*, and is expressed by a St. Andrew's cross, or falser.

Aristotle calls *dieses* the elements of voice, as letters are those of discourse. Indeed Aristotle's *dieses* were apparently different from ours: and we find Vitruvius expressly making the *diesis* a fourth part of the tone. But the Pythagoreans, who are held the inventors of the name *diesis*, did not make it so small: they only divided the tone into two unequal parts, and called the lesser, *diesis*, or *limma*, expressing the interval $\frac{1}{12}$, which we call the lesser semi-tone; and the greater, which we call the greater semi-tone, they called *epitone*.

But in after-times, when the tone came to be divided into three and four parts, the name *diesis* was retained to them all. And hence those different accounts, which we meet with in authors, of the quantity of the *diesis*.

DIESIS, *Enharmonicis*, is the difference between a greater and lesser semi-tone. See *TOKE*, *GENUS*, *DIATHESE*, *SCALE*, &c.

Diesis are divided into three kinds: the lesser *enharmonicis diesis*, or *simple diesis*, denoted by a single cross, raises the note following to two commas, or about $\frac{1}{4}$ of a tone. The logarithm or measure of the octave being 1,000,000, the measure of the *diesis* $\frac{1}{12}$ will be 0,03215. Hence 29 *dieses* will be nearly equal to the octave. See *INTERVAL*.

The *chromatic*, or *double diesis*, denoted by a double cross, raises

raises the following note by a lesser semi-tone, or about four commas; which is the common *disfa*. The ratio of this *disfa* is $\frac{3}{2}$.

The greater chromatical *disfa*, denoted by a triple cross, raises the note by six or seven commas, or about $\frac{1}{2}$ of a tone. None but the double *disfa* is used in music. A flat is frequently used to take away the *disfa*, and a *disfa* to take away a flat.

When semi-tones are placed where regular tones should be, or a tone where there should be a semi-tone: it is called a *disfa* or *fanta*.

DIESIS, among the *Modern Musicians*, denotes those signs or characters which are used to express the several degrees whereby a sound may be elevated above, or depressed below its natural situation; and it either affects the note before which it is placed, or the whole KEY. See SHARP.

DIESPITER, in *Antiquity*, a name given to Jupiter.

Some authors will have it the same with *Dian Pater*, *Jupiter sator*; Jupiter being called in Greek *Ζευς*, or *Δις*, whence the oblique case *Διός*, &c. Others hold *Diespiter* to signify *Dian pater*, father of the day. St. Augustine derives the name from *dies*, day, and *pater*, production, bringing forth; it being Jupiter that brings forth the day. Of which sentiment were Servius and Macrobius; the former adding, that in the language of the *Œci* they called him *Lucinus*, as *Diespiter* in Latin. Stravins, *Antiq. Rom. Synt. C. 1.* seems to intimate, that *Diespiter* signified *Pluto*; but, if that be his meaning, he is apparently mistaken. For both in Cicero, and in the inscription he quotes from Gruter, xxi. 8. we have only *Dii pater*, and not *Diespiter*.

DIET, *Diata*, in *Medicine*, &c. a regimen, or course of living, proper in regard to health.

The word *diet*, in this sense, comes from *diata*, which signified anciently a *banqueting-room*; and at length an *assembly of the states*, because the Germans held most of their councils at table.

The word is formed from the Greek *διαίτα*, which signifies *regimen*, or *rule of life*, prescribed by physicians. And as the physicians usually order a spare, scanty proportion, less than is usually taken, *diet* has with many passed into a name for this retrenchment, or diminution of the ordinary quantity of food, whether it be by advice of a physician, or by a person's own choice; provided it be to remove, or prevent, some disorder.

Judge Blackstone observes, that, as to excess in *diet*, there remains one ancient statute unrepealed, viz. 10 Edw. III. stat. 3. which ordains that no man shall be served, at dinner or supper, with more than two courses, except upon some great holidays there specified, in which he may be served with three. Comm. vol. iv. p. 171. A *spare diet* is a sovereign remedy against all diseases arising from repletion.

It is founded on this, that nature ought not to be burdened and distracted in the concocting of food, but left wholly to her work of digesting and expelling the morbid matter.

For the advantages of a *spare simple diet*, see ABSTINENCE. As no substance is absolutely and of its own nature, either salutary or noxious, but derives either the one or the other quality from its particular relation to the human body; so it is certain, that the effects of the non-naturals must bear a direct proportion to the different constitutions of those who use them: since in these, their consequences must vary, and prove either of the salutary or noxious kind, according to the different causes which concur to produce them.

Hence it is obvious, that the physician acts a preposterous and unaccountable part, who to every one prescribes the same method of living; or thinks that what contributes to the health of one, will without distinction or reserve prove salutary to all. For we are sufficiently taught by daily experience, that all substances are not equally adapted to all patients; and that what one may bear without being sensible of any bad effects, may to another prove prejudicial, and even fatal. Time itself has a considerable influence in determining the salutary or noxious effects of aliments; since some substances may safely, and without any bad consequence, be used at one season, which at another may contribute not a little to the destruction of health.

At different seasons of the year different regimens are to be used, because a change in the state of the atmosphere induces a proportionable alteration in animal bodies.

In the winter, the fibres in consequence of the increased elasticity of the air, are stronger, and better qualified for performing their several motions, and assisting the concoction of the aliments; for which reason we can far better bear aliments of difficult digestion in that season, than in any other. As during winter transpiration is in some measure obstructed, the cutaneous ducts being

braced up by the cold air, the use of rich wines, and strong ales, becomes highly proper. It is also expedient to make frequent use of warm broths and infusions; and care is always to be taken, that the perspiration bear a proportion to the quantity of aliment used.

In the spring, something is to be retrenched from the quantity of our aliments, and the liquor we usually drink is somewhat to be enlarged.

In the autumn the same phenomena are to be observed as in the spring; because the inclemency of the air is the same, and the changes of the weather equally sudden and frequent; by which means perspiration, which is absolutely necessary for health, is easily obstructed; and because at this season the equinoctial happens, diseases are to be prevented by what we call preservative cures.

During the summer, health is most effectually preserved by vegetables, and draughts of diluting liquors; but we are to abstain from such aliments as are heavy, and of difficult digestion, from wine and brandy.

The diet should also be adapted to different constitutions. Persons, whose solids are weak and relaxed, should avoid all viciid food, or such things as are hard of digestion. Their diet, however, ought to be solid, and they should use much exercise in the open air. Those who abound with blood should use sparingly every thing that is highly nourishing, as fat meat, rich wines, strong ale, &c. Their food should consist mostly of bread, and other vegetables, and their drink ought to be water, whey, or small beer. Fat people should abstain from oily, nourishing diet; and they ought frequently to use radish, garlic, and spices, in order to promote perspiration and urine. Their drink should be water, coffee, tea, and the like; and they ought to take much exercise, and little sleep. The course of the lean should be opposite to this. Those who are troubled with acridities should live much on flesh meats; and those who are afflicted with hot alkaline circulations should chiefly use acid vegetables. Those who are subject to the gout, low spirits, hypochondriac, or hysterical disorders, should avoid all flatulent food, every thing viscid, and hard of digestion, all salted or smoke-dried provisions, and whatever is apt to turn sour on their stomachs. Their food should be light, spare, cool, and of an opening nature.

The diet should also be adapted to the manner of life, and age, as well as to the season and constitution: those whose business and profession lead them to a sedentary life, should be more sparing as to the quantity, and more attentive to the quality of their diet, than those that are accustomed to much exercise; they ought to be particularly cautious in the use of every thing that is sour, windy, rancid, and hard of digestion. Particular diseases should likewise make us avoid any thing that has a tendency to increase them. Gouty persons should not use rich wines, strong soups, nor acids. Persons subject to the gravel should shun all astringent and astringent aliments, and the scorbutic should not indulge too much in animal food. The food in early life should be light, but nourishing, and frequently used; food that is solid, with a sufficient degree of tenacity, is most proper for the state of manhood; and the diet of the later period of life, should resemble that of the first. At every period of life, gluttony and fasting should be equally avoided; both the one and the other destroys the powers of digestion; and the frequent repetition of aliments is not only necessary for repairing the continual waste of our bodies, but likewise to keep the humours found and sweet. It should be remarked, however, by way of caution, that one meal of flesh meat in the twenty-four hours, is sufficient. The quantity of animal food consumed by the English is generally pernicious, because it produces but little of that air which is antiseptic: hence they are subject to the scurvy, and its numerous train of consequences, indigestion, low spirits, hypochondriacism, &c. whereas if vegetables and milk, whose antiseptic quality, arising from the gas or air which they plentifully afford, is now generally allowed, were more used in diet, we should have less scurvy, and likewise fewer putrid and inflammatory fevers. See PUTREFACTION AND SCURVY.

Different sexes also require a different diet and regimen. Women are weaker than men, and for that reason require a diet and regimen peculiar to themselves; they are of a spongy and lax habit, and for the most part addicted to indolence and pleasure, drink little, have bodies of a highly delicate and sensible nature, much inclined to spasms, and convulsive motions, and disposed to generate a redundancy of blood. Beside, at certain stated times, they have a regular evacuation by the veins of the uterus; and in consequence of these circumstances it is necessary that women, rather than men, should observe a regimen and method of living, peculiarly and accurately adapted to their habit and constitution. Pregnant women are also to have a regimen peculiar to them.

themselves directed for them, lest the mother herself or the *fetus* should sustain any injury: for the infant included in the *utero* is as it were a part of the mother's body. James, from Hoffman; and Buchan's Domestic Medicine, chap. iii.

Dr. Cheyne shews, how one may supply the place of medicines by *diet*: any one, says he, may in effect lose a pound of blood, take a purge, or a sweat, by dropping the great meal, or abstaining from animal food, and strong liquors, for four or five days, in chronic cases, as effectually as by opening a vein, swallowing a dose of pills, or taking a salubrious bolus. He advises, therefore, all gentlemen of a sedentary life, and of learned profligates, to use as much abstinence as possibly they can, consistently with the preservation of their strength, and the freedom of spirits. This they ought to have recourse to, as soon as they find any heaviness, inquietudes, restless nights, or aversion to application; either by lessening one half their usual quantity of animal food, and strong liquors, till such time as they regain their wonted freedom; or by living a due time wholly on vegetable *diet*, as sage, rice, pudding, and the like; and drinking only wine and water. See DISEASE.

One great reason why leprosy, hot scurvy, dysenteries, plague, pestilential fevers, and the like distempers, formerly so frequent in London, are now so rare, is the change that has been made in the diet of the inhabitants. Hopped beer, wine, and spirituous liquors coming into general use, have been a great means of suppressing putrid diseases; greens and fruit are likewise more universally eat, and salted meats make a much less part of *diet* than formerly: to which may be added the more general consumption of tea and sugar.

A vegetable diet is most proper for scorbutic and hectic persons, and does very well with people who have not much exercise; but in other circumstances, a mixed diet of vegetable and animal substances, such as is commonly used, seems best calculated to nourish and preserve the body from decay.

Irregularities in *diet* are commonly, though unjustly, supposed to have the greatest share in producing military distempers. Were this the case, the changes in the weather and seasons would not so remarkably affect their health; the soberest and most regular corps would not be so sickly; different nations in the same camp, living variously, would not be afflicted with the same distempers; nor would there be such an inequality in the numbers of the sick in different years, were the greatest part of diseases owing solely to *diet*.

Against excess, the most common error in *diet*, the smallness of a soldier's pay is a sufficient security; in regard to them, therefore, the danger lies on the other hand; for, when all are not obliged to eat in messes, some will be apt to lay out their pay upon strong liquors, and to squander away in one day what is but barely a maintenance for a week; but, on the supposition that every man contributes his share to a mess, we may be assured there can be no errors in *diet* of any consequence, whilst almost the whole pay is spent upon common food.

As to the abuse of spirits and fruit, soldiers are generally blamed without any foundation; spirits being rather beneficial than hurtful to them, so often exposed to the extremes of heat and cold, to moist and bad air, long marches, wet cloaths, and scanty provisions; and as to fruit, a few disorderly men may rob orchards, which is the only way they can come at fruit, but the camp diseases are incident to the most regular equally with them. A fundamental rule in regard to the *diet* of soldiers, is to oblige them to eat in messes, by which means their pay will be laid out upon wholesome food. The greatest impediment to messing are the wives and children, who must often be maintained on the soldier's pay; in which circumstances it is not improper food, but the want of it, that may endanger a soldier's health.

The messing being established, there remains only to see that the men be well supplied with bread, and that the markets be so regulated that the traders may have encouragement to come to the camp, and the messes have good provisions at a moderate price; and particularly vegetables, which, during the hot weather, ought to make a great part of the *diet*. In establishing the messes, some regulations might be made with regard to an allowance of spirits, either by stoppages on the pay or otherwise. This is already practiced in the navy, and probably for the same reasons that make spirits necessary for soldiers; since in ships men are liable to distempers from moist and corrupted air.

As to the *diet* of officers, their chief rule, in sickly times, is to eat moderately, avoiding all surfeits and indigestion, and using wine in moderation. Pringle's Obs. on the Diseases of the Army. See FOOD.

DIET-drinks, a form of physic, including all the medicated Vol. II. N° 97.

wines, wheys, and ales, used in chronic cases. They require a course or continuance to answer any intention of moment. In acute cases they are of no use; but where the disorder of a constitution is gradually to be gained upon, much help may be had from them.

DIET, or **DYET**, is also used for an assembly of the states, or circles of the empire, or Poland, to deliberate and concert measures for the public good.

The general diet of the empire is ordinarily held at Ratisbon. It consists of the emperor in person, or by his representative or commissary; the nine *electores*, three of whom are ecclesiastical, and the other six secular, forming the electoral college; the ecclesiastical princes, viz. archbishops, bishops, abbots, and abbesses, and the secular princes, forming the second college; and the representatives of the imperial cities, who constitute the third college, and are divided into two benches, viz. that of Saxia and of the Rhine. This *diet* has been usually summoned by the emperor, but there are some cases in which the electors have summoned it without his consent, or requested him to summon it. In the absence of the emperor, the right of convocation belongs to the king of the Romans. The *diet* makes laws, raises taxes, determines differences between the several princes and states, and relieves the subjects from the oppressions of their sovereigns. The *diet* of the empire were originally the same with the assemblies of March and May, held by the kings of France: they met, at least, once a year; and every freeman had a right to be present. These were assemblies, in which the monarch deliberated with his subjects, concerning their common interest: but when the princes, dignified ecclesiasticals, and barons, acquired territorial and independent jurisdiction, the *diet* became an assembly of the separate states, which formed the confederacy of which the emperor was the head. Robertson's Hist. Charles V. vol. i. p. 462.

The term *diet* is also applied to the assembly of electors for the choice of an emperor or king of the Romans: this is usually held at Frankfort on the Main.

The general diet of Poland is by the laws only to be held every two years; but pressing occasions convene them every year: the laws also confine their sitting to fifteen days, but they frequently protract it to six weeks. The usual place is at Warlaw, the capital of the kingdom: though it has been often held at other places; in effect, as by the laws every third *diet* is to be convened at Grodno, in Lithuania; whenever, for particular reasons, it is judged meet to change the order, and hold it elsewhere, the nobility of the grand-duchy must consent to it. It is the king who fixes the time, and summons it by circular letters sent to all the palatines. In an interregnum, the archbishop of Guesna calls the *diet*.

The several particular *diet*, which are held six weeks before the general one, send three deputies each, chosen out of the members thereof.

In Poland there are likewise *diet*s on horseback, held in the champagne, or country: such are those wherein they choose their king. They are called *pospites*.

There are likewise *diet*s held in Switzerland; *diet*s of the protestant cantons; *diet*s of the catholic cantons; and general *diet*s. The first assembly at Araw, and are convoked by the canton of Zurich; the second at Lucern, convoked by the canton of that name; the third, composed of the deputies of all the cantons, both protestant and catholic, is held twice a year, at the end of June and the beginning of December, and meets at Baden. It is the canton of Zurich which has the right of convening it.

DIETA, in our Old Law Book, denotes a day's journey. *Omnia rationabilis dicta consistit ex viginti miliaribus*. **DIET**, **DIETETIC**, **DIETETIC**, that part of physic which considers the way of living, with relation to food, suitable to particular cases. See DIET.

DIEU *mon droit*, q. d. *God and my right*, the motto of the arms of England, first given by king Richard I. to intimate, that he held not his empire in vassalage of any mortal.

It was afterwards taken up by Edward III. when he first claimed the crown of France; and was continued, without interruption, to the time of king William III. who used the motto *Je maintiendrai*; though he commanded the former to be retained on the great seal. The same is to be understood of the late queen Anne, who used the motto, *Semper parati*; which had been before used by queen Elizabeth.

DIEU *in ait*, in Law, are words often used in our old law; and it is a maxim in law, that the act of God shall prejudice no man. Therefore if a house be blown down by a tempest, thunder, or lightning, the lessee or tenant for life or years, shall be excused in waite. Likewise he hath by the law a special interest to take timber to build the house again for his habitation. 4 Rep. 63 11

Rep. 82. So when the condition of a bond conflicts of two parts in the disjunctive, and both are possible at the time of the obligation made, and afterward one of them becomes impossible by the act of God, the obligor is not bound to perform the other part. § Rep. 22. And where a person is bound to appear in court at a certain day, if before the day he die, the obligation is saved, &c. See BOND.

DIEAH-EDRIA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *dis*, twice, &c. *for*, and *spars*, *file*. The bodies of this genus are spars, composed of twice six planes, being formed of two hexedral pyramids, joined base to base, without any intermediate column. Of this genus there are only two known species: 1. One with long, narrow, and sharp-pointed pyramids, found in Lamb's-cave, on Mendip-hills; and 2. One with long, broad, and obtuse pyramids: this is found in the mine of Gofflar in Saxony, and in many of the mines of the Harz Forest. Hill's Hist. of Fossils, p. 212.

DIEODODUS, *diodes*, in *Rhetoric*, is used for digression. **DIFF**, is the name of an instrument of music among the Arabs, serving chiefly to beat time to the voice: it is a hoop, sometimes with pieces of brass fixed to it to make a jingling, over which a piece of parchment is distended. It is beat with the fingers, and is the true *tympanum* of the ancients. Russell's Hist. of Aleppo, p. 94.

DIFFAMATORY. See **DEMATORY**.

DIFFARREATION, among the Romans, a ceremony whereby the divorce of their priests was solemnized. The word comes from the preposition *dis*; which is used, in composition, for *divisor*, or *separation*; and *farreum*, a ceremony with wheat, of *for*, wheat.

Diffarreatio was properly the dissolving of marriages contracted by consanguinity: which were those of the pontifices, or priests. Festus says, it was performed with a wheaten cake. Vigenere will have consanguinity and *diffarreatio* to be the same thing.

DIFFERENCE, in *Logic*, an essential attribute belonging to some species, and not found in the genus; being the idea that defines the species.

Thus, body and spirit are the two species of substance, which in their ideas include something more than is included in the idea of substance. In body, for instance, is found impenetrability, and extension; in spirit, a power of thinking, and reasoning: so that the difference of body is impenetrable extension, and the difference of spirit is cognition.

DIFFERENCE, in *Mathematics*, the excess of one quantity above another.

When a less quantity is subtracted from a greater, what remains is called the difference.

It was a fundamental principle among the ancient geometers, that the difference of any two unequal quantities, by which the greater exceeds the lesser, may be added to itself, till it shall exceed any proposed finite quantity of the same kind. This principle seems inconsistent with the supposition of an infinitely small quantity or difference, which added to itself any number of times, is never to be supposed to become equal to any given quantity whatsoever; which is the foundation of the modern method of infinitesimals. However, this last may, with proper caution, be made useful and accurate.

DIFFERENCE of longitude of two places, is an arch of the equator intercepted between the meridians of the places.

DIFFERENCE, *Alcivinal*, in *Astronomy*. See **ALCIVINAL**.

DIFFERENCES, in *Heraldry*, certain additions to coat-armour; whereby something is altered, or added, to distinguish the younger families from the elder, or to show how far they are removed from the principal house. They are called, in Latin, *diminutiones*, and *discreta armorum*; and, by the French, *brisures*.

Of these differences Styl. Morgan gives us nine, which obtain principally among us: viz. the *label*, which denotes the first and eldest son; the *rescent*, the second; the *mullet*, the third; the *martlet*, the fourth; the *azulet*, the fifth; the *fiar de lis*, the sixth; the *rose*, the seventh; the *cross-moline*, the eighth; and the *eight-fall*, the ninth. See each under its proper article.

Again, as the first differences are single for the sons of the first house, or descent; the sons of the younger houses are differed by combining, or putting the said differences upon each other. As the first differences are, the *label*, *rescent*, &c. for the first house; the difference for the second house is the *label* on a *rescent*, for the first of that house, during his father's life only; for the second, a *rescent* charged with a *rescent*; for the third brother of the second house, a *mullet* on a *rescent*, &c.

Sisters, except of the blood-royal, have no other mark of difference in their coats of arms besides the form of the escutcheon. See **LOZENGE**.

The original of difference is controverted. Camden will

have them to have begun about the time of king Richard I. Paradin assigns differences worn as early as the year 870. The president Fauchet observes differences to have been hereditary in the French families before the time of Louis le Gros, who came to the crown in the year 1110. Moreau refers them to the time of St. Louis; and Lallouette, Belleforest, &c. to that of Philip Augustus. The occasion of their rise is well accounted for by Colmbiere.

All nations, says he, prefer the eldest brothers to the younger; whence those, in a direct line, succeeding to their fathers, and becoming masters of their lands, took on them their coat-armour, without any change, or alteration; and transmitted the same again to their eldest sons; the younger brothers, or bastards, not being allowed to bear the same arms, without some additional mark, to distinguish them from the elder. Hence some heralds, he goes on, have endeavoured to confine them to certain fixed and determinate figures, for distinguishing the second from the first, the third from the second, and so on to the sixth; assigning the second a *label*, the third a *rescent*, the fourth an *erle*, the fifth a *fatow*, and the sixth a *head of cattle*.

And the descendants of these to bear double differences, or differences charged on one another; viz. the eldest son of the second line to retain his paternal coat, with the difference of the label of three points; the second, the label of four points; the third, such a label on a chief; the fourth, a label charged with certain figures, as *angels*, *livels*, *martlets*, *erlecoats*, *rosetts*, &c. And, for the same reason, the second son of the third son shall bear a *border* engrailed; the third, a *border* charged with *bransons*, or *tourneaux*, &c.

But the same author judges the fixing of any certain inviolable differences at all an abuse; because they may happen not to be agreeable to the paternal coat, but very much deface and blemish it. He adds, that many other figures, besides those above mentioned, may be used as differences; as shells, bezants, cinquefoils, and a thousand more. Some younger families have made the difference in their arms by only diminishing the ordinaries, or changing the posture; and others, by only changing the metal, or colour.

It must be added, that the difference may be of metal on metal, or colour on colour; which, in other cases, is false heraldry.

Differences, *Ancient*. See **BORDURES**.

DIFFERENTIAL, *Differentialis*, in the *Higher Geometry*, an infinitely small quantity, or a particle of quantity so small as to be less than any assignable one.

It is called a *differential*, or *differential quantity*, because frequently considered as the difference of two quantities; and, as such, it is the foundation of the differential calculus. Sir Isaac Newton, and the English, call it a *moment*, as being considered as the momentary increase of quantity.

Mr. Leibnitz, and others, call it also an *infinitesimal*. See **INFINITESIMAL**.

DIFFERENTIAL, of the first, second, &c. degree. See **DIV-
ERENTIO-DIFFERENTIAL**.

DIFFERENTIAL calculus, or *method*, is a method of differencing quantities; that is, of finding a differential, or infinitely small quantity, which, taken an infinite number of times, is equal to a given quantity. See **CALCULUS**, and **FLUXIONS**.

**DIV-
ERENTIO-DIFFERENTIAL Calculus**, is a method of differencing differential quantities.

As the sign of a differential is the letter *d*; that of a differential of *dx* is *d dx*, and the differential of *d dx*, *d d dx*, or *d² x*, *d² x*, &c. or *x*, *dx*, &c.

Thus we have powers, or degrees, of differentials. The differential of an ordinary quantity, is called a differential of the first power, or degree; as *dx*.

**DIV-
ERENTIAL** of the second power, or degree, is an infinitesimal of a differential quantity of the first degree; as *d dx*, or *d d dx*, or *d² x*, *d² x*, &c.

**DIV-
ERENTIAL** of the third degree, is an infinitesimal of a differential quantity of the second degree; as *d d dx*, *d³ x*, *d³ x*, &c. and so on.

The powers of differentials, as *d² x*, are differenced after the same manner, as the powers of ordinary quantities; and, again, as compound differentials either multiply, or divide, each other, or are powers of differentials of the first degree, differentials are differenced after the same manner as ordinary quantities; and, therefore, the differential-differential calculus is the same, in effect, with the differential.

**DIV-
ERENTIAL**, in the *Dactrines of Logarithms*. Kepler calls the logarithms of tangents, *differentialis*; which we usually call *artificial tangents*. See **LOGARITHM**, **MES-
LOGARITHM**, and **TANGENT**.

**DIV-
ERENTIAL equation** is used by some mathematicians for

for an equation involving infinitesimal differences, or fluxions. Thus the equation $3x^2 dx - 2xy dx + y^2 dy = 0$ in the foreign notation, or $3xy - 2xy + y^2 = 0$ in the English notation, is called a *differential equation*. But these equations should, consistently with the English, or Sir Isaac Newton's notation, be rather called *fluxional equations*. Hence some of our mathematicians have applied the term *differential equation* in another sense, to certain equations defining the nature of series. See *SERIES*.

DIFFERENTIAL method, in *Mathematics*, an appellation given to a method of describing a curve of the parabolic kind through any given number of points.

This method is given by Sir Isaac Newton in the fifth lemma of the third book of his *Principles*. He distinguishes two cases of this problem; the first, when the ordinates drawn from the given points to any line given in position, are at equal distances from each other; and the second, when these ordinates are not at equal distances. He has given a solution of both cases, but without demonstration in that place, which has since been supplied by himself and others. See his *Methodus Differentialis*, published with other tracts of the same author, by Mr. Jones, London, 1711; and Stirling's explanation of the Newtonian *differential method*, in the *Phil. Trans.* No. 362. Cotes, *De Methodo Differentiali Newtoniana*, in his works published by Dr. Smith; Hermann. *Phoronomia*; and Le Seur and Jacquier, in their *Comment on Sir Isaac's Principles*.

Where it is to be observed, that the methods there demonstrated by some of these authors extend to the description of any algebraic curve through a given number of points, which Sir Isaac, writing to Mr. Leibnitz, mentions as a problem of the greatest use.

By this method, some terms of a series being given, and supposed to be placed at given intervals, any intermediate term may be found nearly; and this therefore gives a method for interpolations. Newton. *Method. Differ.* prop. 5.

Any curvilinear figure may also be squared nearly, of which some ordinates may be found. Newt. *ibid.* prop. 6.

And this method may be extended to the construction of mathematical tables by interpolation. *Ibid.* in *Schol.* p. 100.

The successive differences of the ordinates of parabolic curves, becoming ultimately equal, and the intermediate ordinate required being determined according to Sir Isaac's rules, by these differences of the ordinates, is the reason of this method being called the *differential method*. To be a little more particular.

The first case of Sir Isaac's problem amounts to this: a series of numbers, placed at equal intervals being given, to find any intermediate number of that series when its interval from the first term of the series is given.

Subtract every term of the series from the next following, and let the remainders be called first differences; then subtract each difference from the next following, and let these remainders be called second differences; again, let each second difference be subtracted from the next following, and let the remainders be called third differences, and so on; then if A be the first term of the series, d' the first of the first differences, d'' the first of the second differences, d''' the first of the third differences, &c. and if x be the interval between the first term of the series and any term sought, E , that is, let the number of terms from A to E , both inclusive, be $= x + 1$, then will the term sought,

$$E = A + \frac{x}{1} d' + \frac{x \cdot x - 1}{1 \cdot 2} d'' + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} d''' + \frac{x \cdot x - 1 \cdot x - 2 \cdot x - 3}{1 \cdot 2 \cdot 3 \cdot 4} d^{(4)} + \text{&c.}$$

which series differs from the Newtonian in this, that the quantities $\frac{x}{1 \cdot 2}$, $\frac{x \cdot x - 1}{1 \cdot 2 \cdot 3}$, $\frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3 \cdot 4}$, &c. here used, signify the same with d' , d'' , d''' , &c. used by Sir Isaac.

Hence, if the differences of any order become equal, that is, if any of the quantities d' , d'' , d''' , become $= 0$, we shall have a finite expression for E , the term sought; it being evident, that the series must terminate when any of the differences d' , d'' , &c. become $= 0$.

It is also evident that the coefficients $\frac{x}{1}$, $\frac{x \cdot x - 1}{1 \cdot 2}$, &c. of the differences, are the unciæ of the binomial theorem.

A method may be deduced from the foregoing theorem, of finding the sums of the terms of such a series. For if we imagine a new series, whereof the first term shall be $= 0$, the second $= A$, the third $= A + B$, the

fourth $= A + B + C$, the fifth $= A + B + C + D$, and so on; it is plain that the assigning one term of this series is finding the sum of all the terms A , B , C , D , &c. Now since those terms are the differences of the sums 0 , A , $A + B$, $A + B + C$, $A + B + C + D$, and that, by the supposition, some of the differences of A , B , C , D , &c. are $= 0$; it follows that some of the differences of the sums will also be $= 0$; and that whereas in the series $A + B + C + D + \dots$, &c. whereby a term was

assigned, A represented the first term, d' the first of the first differences, and that x represented the interval between the first term, and the last, we are to write 0 instead of A , A instead of d' , d' instead of d'' , &c. and $x + 1$ instead of x ; which being done, the series expressing the sums will be $0 + x + 1$.

$$A + \frac{x+1}{1 \cdot 2} d' + \frac{x+1 \cdot x}{1 \cdot 2 \cdot 3} d'' + \text{&c. or } x + 1 \times A + \frac{x}{2} d' + \frac{x \cdot x - 1}{2 \cdot 3} d'' + \frac{x \cdot x - 1 \cdot x - 2}{2 \cdot 3 \cdot 4} d''' + \text{&c.}$$

Or again, if the real number of terms of the lines be called n , that is, if $n = x + 1$ or $n - 1 = x$, we shall have

$$\text{the sum of the series } = x \times A + \frac{x-1}{2} d' + \frac{x-1 \cdot x-2}{2 \cdot 3} d'' + \text{&c.}$$

See *De Moivre*, *Doct. of Chances*, p. 59, 60. *Mis. Analyt.* p. 153.

For instance, let it be required to find the sum of a series of the squares of the natural numbers $1 + 4 + 9 + 16 + 25 + 36$. Then, $A = 1 d'$

$$\begin{array}{r} 4 \\ 9 \\ 16 \\ 25 \\ 36 \end{array} \quad \begin{array}{r} d'' \\ d''' \\ d^{(4)} \\ d^{(5)} \\ d^{(6)} \end{array}$$

The sum consequently will be,

$$\begin{aligned} &= x \times 1 + \frac{x-1}{2} \times 3 + \frac{x-1 \cdot x-2}{2 \cdot 3} \times 2 \\ &= x \times 1 + \frac{3x-3}{2} + \frac{x^2-3x+2}{3} \\ &= x \times \frac{6-x+0+3+2x-6x+4}{6} \\ &= x \times \frac{1+3x+2x^2}{6} = \frac{x \cdot 1 + x \cdot 3 + x \cdot 2x}{6} = \frac{6 \cdot 7 \cdot 13}{6} = 91. \end{aligned}$$

This easy example will be sufficient to show the applications of this rule. Those who are desirous of seeing its use in questions of chance, may consult *M. De Moivre's Doctrine of Chances*, p. 59. seq. Various other instances of the use of this rule in finding sums of progressions of figurate members, &c. may be seen in *Misc. Analyt.* p. 154, seq.

As to the *differential method*, it is to be observed, that though Sir Isaac and others have treated it as a method of describing an algebraic curve, at least of the parabolic kind, through any number of given points; yet the consideration of curves is not at all essential, though it may help the imagination. The description of a parabolic curve through given points, is the same problem as the assigning of quantities from their given differences, which may always be done by algebra, and by the resolution of simple equations. See *Mr. Stirling's Methodus Differentialis*, p. 97. This ingenious author has treated fully of the *differential method*, and shown its use in the solution of some very difficult problems. See *SERIES*.

DIFFERENTIAL scale, in *Algebra*, is used for the scale of relation subtracted from unity. See *RECURRING SERIES*.

DIFFORM, *Difformis*, from *forma*, *shape*, is a word used in opposition to *uniform*; and signifies, that there is no regularity in the form, or appearance, of a thing.

The botanists use it as a distinction of the flowers of several species of plants.

DIFFRACTION, in *Optics*, a term first used by Grimaldi the Jesuit, to denote that property of the rays of light, which others have called *INFLECTION*; the discovery of which some attribute to Grimaldi, and others to Dr. Hooke.

DIFFUSE, *Diffusive*, is chiefly used for a prolix manner of writing, &c.

A dictionary cannot well be too *diffusive*: for a man is never too much informed of the word he wanted; and he is not obliged to read that part of the explication which does not concern him.

A *diffusive* style is proper for discourses in the demonstrative

fractive kind. Demolition is close, and concise; Cicero, on the contrary, is diffuse.

DIFFUSION, from *diffundere*, *I pour out*, *I dilate*, the act whereby a body is spread, or stretched out, so as to take up more space.

The schoolmen make three kinds of *diffusion*: the first, that whereby a pure quality is *diffused*; as cold, force, &c. This they distinguish into *equal*, whereby equal portions, or degrees, of the quality are distributed upon equal parts of the medium; thus, when a direct motion is impressed on a moveable, all the parts of the moveable receive an equal impetus; and *unequal*, when unequal degrees of the quality are distributed on different parts of the subject: thus it is, that force is impressed on a lever, and cold propagated through a medium.

The second kind of *diffusion* is that performed by the motion of bodies: such is the *diffusion* of light, sound, smell, magnetic, electric virtues, &c.

The third is performed partly by the motion of corpustles, and partly by the *diffusion* of a quality; and thus they hold fire to be *diffused*.

But the modern philosophers reject the notion of qualities, and their *diffusion*. According to them, there is no other *diffusion*, but that of corporeal substance, emitted in minute effluvia, or particles, into a kind of atmosphere all around the body; which *diffusion* of corpustles some call *atmosphærical*, as being supposed to be terminated by a circle, whereof the *diffusing* body is the centre. Every body, it is now proved, has its sphere of activity, or *diffusion*, within which the particles, or corpustles, torn from it, and flying away, have a sensible effect; as we see in odorous, sonorous, &c. bodies. See **QUALITY**; where the physical law of the *diffusion* of qualities is laid down.

DIGAMMA. See **Y**.

DIGAMY, the same with **BIGAMY**.

DIGASTRICUS, in *Anatomy*, a muscle of the lower-jaw, thus called, as having a double belly. See *Tak. Anat. (Anat.)* fig. 2. No. 2.

The word is formed from *dis*, twice, and *gaster*, belly. See **DIAPHYSA**.

The *digastric* muscles, according to Mr. Monro, do not solely pull the lower-jaw down, but serve to draw up the os hyoides, and parts annexed to it, in deglutition. We have an account of the situation and uses of these muscles by this learned professor, in the *Med. Ess. Edinb.* vol. i. art. 11.

DIGEST, **DIGESTIVUM**, a collection of the Roman laws, ranged and *digested* under proper titles, by order of the emperor Justinian.

That prince gave his chancellor Tribonianus a commission for this purpose; who, in consequence thereof, chose eleven jurists, or lawyers, to work upon the same. These, accordingly, took out the best and finest decisions from the two thousand volumes of the ancient jurists, and reduced them all into one body; which was published in the year 529, under the name of the *Digest*. To this the emperor gave the force of a law, by a letter at the head of the work, which serves it as a preface.

The *Digest* makes the first part of the Roman law, and the first volume of the *corpus*, or body, of the *CIVIL LAW*, contained in fifty books.

It was translated into Greek under the same emperor, and called *Pandectæ*. See **PANDECTÆ**.

Cujas says, that *Digest* is a common name for all books disposed in a good order and economy; and hence it is, that Tertullian calls the Gospel of St. Luke, a *Digest*.

Hence also abridgements of the common law are denominated *digests* of the numerous cases, arguments, readings, pleadings, &c. dispersed in the Year-books, and other reports and books of law, reduced under proper heads, or common places. The first was that of Sirham, which comes as low as Henry VI. That of Fitzherbert was published in 1516; Brook's in 1573, of which Hughes's, published in 1663, is a sequel. Rolles, Daines, and Nelson, have also published *Digests* or abridgements of this kind, including the cases of later days to which may be added the New Abridgement, and Viner's Abridgement.

DIGESTION, in *Medicine*, that change of the food, taken in at the mouth, which it undergoes in the stomach, in order to assist fit matter to compose, or increase, an animal, till it arrives at its destined bulk; and to repair the loss of those particles which the body, in its natural state, necessarily undergoes.

The operation of *digestion* succeeds to mastication, and deglutition.

It includes chylification, and is succeeded by sanguification, and nutrition.

The cause, manner, and means of *digestion*, have been infinitely controverted: it would be tedious to enter into all the systems, and hypotheses that have been framed

by philosophers and physicians, to account for this important operation. Some contend, that it is done by a kind of elixation, or boiling, of the solid and grosser parts of the food in the liquid, by the heat of the stomach, and of the adjacent parts, the liver, spleen, &c. Others will have it done by attrition; as if the stomach by those repeated motions, which are the effects of respiration, rubbed or ground off the minutest particles from the grosser matters; and agitating, and driving the rest against each other, attenuated, and dissolved them. Others think, the bilious juice; others the spirits, &c. chiefly concerned in the affair.

Others will have the food dissolved by a menstruum, or solvent: but these are greatly divided as to the nature and origin of this menstruum; some supposing it an acid, furnished by the glands of the stomach; others a nitro-aerous spirit, which, by penetrating the mass of food, breaks the connexion of the most solid parts; and others, a saline juice, which divides and volatilizes the parts of the food.

Others, again, suppose *digestion* to be performed by means of a ferment, or leaven; which, mixing with the aliment, excites an intestine motion in the parts thereof, by whose mutual collisions, the parts are attenuated and dissolved.

But these, too, differ in their opinions of this ferment; some taking it to be the remains of the food last *digested*, which, by its continuance in the stomach, has contracted an acid quality, which renders it a ferment; others take the ferment, or principle of fermentation, to be contained in the aliment itself; which, when enclosed in the stomach, and heated thereby, being put in motion, enters on its office of fermentation; but these, too, are divided; some taking it to be the spirituous part; and some the oil in foods.

Others suppose the matter of this ferment supplied by the glands of the stomach; and lastly, others contend for the saliva, and make that the ferment serving principally for the *digestion* of the food.

All these systems are now reduced to three principal ones; which we shall find explained, and defended in the several later writings on that subject: the first holding *digestion* to be performed by fermentation; the second by trituration; and the third by fermentation and trituration together.

The first opinion was for a long time the only one. The retainers of it hold, that the food, after it is received into the stomach, is there impregnated with certain menstruous juices, which being assisted by the natural heat of the stomach, raise a fermentation in the foods, which dissolves, attenuates, and converts them into chyle, which is a liquor in a state of actual fermentation.

This was, originally, the system of the ancients; who, though they only express themselves in general terms, as dissolving, softening, subduing, concretizing qualities, &c. yet seem to have the notion of what we call *fermentation*. Thus Empedocles and Hippocrates teach, that *digestion* is performed by a putrefaction of the foods, after the like manner as the same Empedocles holds water to be converted by putrefaction into wine. Hippocrates and Aristotle used the term *æmulsion*, which we likewise find in Erotian, Plutarch, and Aëtius, to express the manner of fruits ripening, the must changing into wine, and paste rising. Hippocrates expressly names *effervescence* and *fermentation*, *De Veteri Medicina*, cap. 5. and Galen likewise, *L. de Confectudinibus*, cap. 2. And in another place he asserts, that a certain ferrous juice of the stomach concurs with the bile and spirits to effect *digestion*. To say nothing of Cicero, who, according to the prevailing opinion of his time, attributes *digestion* to the heat of the stomach. Lib. ii. *De Nat. Deor.*

Van Helmont, in his *Treatise De Flanibus*, has applied the doctrine of *fixed AIR*, now more generally understood, to the explication of the phenomena of *digestion*; and Hoffman also, in his chapter *De Alimentorum Solutione & Salivæ Ufu*; and the three succeeding ones, insists much on the complete change which the aliment undergoes in the first passages, and makes *digestion* a mere fermentary process.

The juices, or ferments in the stomach, to whose action *digestion* is supposed owing, are, the saliva, bile, and pancreatic juice. This is to be true, that in certain voracious animals, which eat, and *digest* fast, particularly wolves, ostriches, and porcupines, the bile discharges itself immediately into the cavity of the stomach; and we have observed a disposition analogous thereto in a man that had been a great eater.

There are only three marks to know the fermentation of dough and mull by: first, in that the dough rises and swells; and the mull bubbles and rarefies; secondly, in that the bread and wine made by these fermentations have different tastes and qualities from those the flour

and must had before; thirdly, in that the bread and wine, by distillation, yield principles that differ in many respects from those drawn from flour and must. Now, all these characters are found in the change made in the food by *digestion*.

Sir John Pringle made several curious experiments, in order to ascertain the fermentative quality of animal and vegetable substances. Bread and water remained for several days in a heated furnace, without any fermentation; but two drams of fresh meat being added to double the former quantity of bread, and water in proportion, the mixture began to ferment in a few hours, and continued to do so about two days. The fermentation was generally so strong that if the cakes had not frequently given way, the phials must have burst. The bread and flesh, which at first lay at the bottom, soon rose to the top, and constantly, as the air elapsed, fell some particles, that had been buoyed up by the fluid; thus a sediment was formed resembling lees, whilst the lightest part, or flowers, remained on the surface; but the fermentation continuing, these also subsided; and the acid taste and smell of the liquor, after the action ceased, was a farther proof of the preceding fermentation. This change was the more extraordinary, because, when the motion began, the mixture was tending to corruption, and in a few hours afterwards became actually offensive; but the next day the putrid smell abated and went off, before the fermentation ceased.

From this and several other experiments of the same kind, Sir John infers, that most animal substances tending to putrefaction are endowed with a power of raising a fermentation in the *fermentum*, and even of renewing that action in such as have undergone it before. It appears also plain by his experiments, that there is somewhat generated, or set free, during the first stage of the fermentation of animal and vegetable mixture, which hath a power of correcting putrefaction. The effect of fermentation is evidently to change putrid substances into a state of acidity, which they not only retain, but become still more and more acid. It is observed, indeed, that the acid arising from fermentation has something of an austere and salubrious taste, but without any offensive smell. Now, considering how much air is generated by fermentation, it may seem strange that the same materials, used as food, should make so little disturbance in the body; and the difficulty would be the greater, did the SALIVA, as some suppose, promote both fermentation and putrefaction.

From this theory of fermentation, the doctor accounts for the acidity of the stomach; a disorder to which many people are subject; since not only a strong, but an austere acid, may be produced from the food of those who live on flesh, bread, and water only, as often as the stomach is relaxed, or in any way disabled from conveying the whole aliment into the intestines; for what is left, having time to undergo a complete fermentation, is thereby changed into a harsh sort of vinegar. See *DIARRHOEA*.

It is further observed, that spirits, wines, acids, bitters, aromatics, and the better antiscorbutic plants, retard alimentary fermentation, by their power of correcting putrefaction. However they may have their several uses; some for checking immoderate fermentation, when, by reason of a putrid effluvia, or defect of it, the aliment may ferment too violently; and others, begin for bracing the stomach, and fitting it for expelling its contents in due time. All these facts correspond with *digestion*; for the most nourishing and digestible food to people in health, consists in a due mixture of animal and vegetable substances with water. Scorbatic or putrid habits require acids, wine, or other antiseptics. And acids abounding in the stomach are corrected by absorbents; and, in a want of a natural heat, and a debility of the stomach, wines, bitters, and warm acid substances, become necessary. OBS. on Diseases of the Army. Appendix.

Fermentations have been usually supposed to generate great heat, and effervescence has been used as a synonymous term, by which to express it. Nevertheless many of the most violent of them are attended with a very considerable cold instead of heat. Thus water poured into spirit of wine produces heat, in proportion to the water; but the essential vegetable oil, which is particularly disposed to take fire, mixed with spirit of wine, produces cold; and water has no effect with these oils. Mem. Acad. Par. 1722.

Several of Sir John Pringle's experiments have been repeated by Dr. Macbride, to which he has added others of the same kind. The following mixtures were prepared, viz. bread and water, about four ounces; bread and boiled mutton, best up thin, with the requisite quantity of water, in all about four ounces; this was called

the simple fermentative mixture: four ounces of this mixture, with two drams of fresh lemon juice; four ounces of the same best up with an ounce of figmace; the same quantity of the mixture with an ounce of green water-cresses; and four ounces, with two drams of a very fetid liquor, that lay about putrid mutton: these several mixtures were placed in a moderate degree of heat, on the top of a sand furnace, which required a continual fire for three or four days. The bread and water discovered no fermentation for fifty-four hours; but at the end of four days it became perceptibly acid. In the other five mixtures, an intestine motion was evident in three or four hours; the solid part soon rose to the top; bubbles of air, and a thick scum, formed on the surface; a vapour, with some degree of pungency, and which extinguished fire, now began to discharge itself; and when the motion became very brisk, little pieces of the solid matter fell every moment to the bottom of the phials; and when it ceased, as it did in the four last, in fifty-four hours, and in the first in four days, the mixtures were clear and perfectly sweet.

From these and many other experiments, both of a similar nature, and on the great quantity of fixed air which is separated from animal substances, during their putrefaction, Dr. Macbride was led to conclude, that on the presence of an elastic fluid, or fixed air, in flesh, depends its cohesion and soundness; that in proportion as the fixed air is separated from it by fermentation, its texture is destroyed, its constituent parts become disunited, and separate to reunite in a different manner, and to form new combinations different from the former. See *PETREFACTIO*.

Having likewise found, that all the alimentary mixtures, which we commonly use, are susceptible of fermentation in a short time; that animal and vegetable substances, when mixed, have a greater aptitude to ferment than either of these substances possess separately; and that from all the alimentary mixtures, which he has tried, he always separated a considerable quantity of fixed air; he applied these different discoveries to explain the phenomena, and to establish the most plausible and rational theory of *digestion*. See the close of the article, and *CHYLE*. See also *FIXED AIR*, and *SCUM*.

Haller denies that any kind of fermentation takes place in the stomach, in order to *digestion*; and seems to attribute the greatest effect, in order to the dissolution of our aliment, to the separation of the air therein contained, and the action of the bile.

The second system was invented, or at least renewed, in the present age; and has been maintained with much zeal and vivacity, as is commonly the case in any thing that has the appearance of novelty. Those who espouse this opinion, contend, that it is a mere continual attrition, or grinding, that breaks, attenuates, and reduces the food, and with the addition of a proper fluid, forms it into that whitish substance, called *chyle*; much as corn is ground between the stones of a mill. Which opinion seems to be confirmed by something observed in birds; their gizzard, or crop, is composed of two strong, solid, compressed muscles, which rubbing against each other, and being assisted by little angular bones, or grains of sand, swallowed by the birds, break and grind the dry food those animals live on; and when the food is ground smooth, they cast them off with the other excrements, and swallow fresh grain.

The experiments of the Florentine academy, repeated by Reil and Borelli, favour the same opinion. Hollow particles of glass, which they gave to chickens, ducks, and turkeys, were found reduced to a fine powder.

This sentiment is thus explained by an able spectator thereof, M. Hecquet, in his treatise of *digestion*. Every thing in the body is calculat; consequently, every thing therein is hollow; every thing therein lives after its manner; consequently, every thing is in motion: animal life being nothing but motion, and consequently, all the vessels are in motion. Now the parts of a body, that are to move, will move most readily towards those sides where they find the least resistence. But the place of the least resistence in tubes is the cavity; consequently, the motion of the parts of vessels is towards their axes. The parts of vessels that are to move, are the parietes, or sides, because flexible and elastic; and this motion can only be effected by an approximation of those parts; consequently, the motion of the vessels consists in an approximation of their parietes; it is, therefore, a sort of contraction, pressure, or coarctation. Hence, as all the parts of the body are only vessels, they all undergo a pressure, pressure, or contraction.

Farther, all these vessels contain juices in their cavities; and, therefore, all the juices, or liquids in the body, are continually compressed. This pressure is the action of an elastic force; consequently, the pressure will be such

is the force, and, therefore, alternative: consequently, it is a pulse, or palpitation; and therefore the juices are continually beaten. Now, these juices are exceedingly divisible; and consequently they are continually attenuated and divided; and a division effected by a pulsation, or beating, is a trituration; and consequently, the juices in the body are continually triturated, or ground. The reason why the compressive force should be alternative, is, that the membranes, which compose the vessels, consist of two plans, or series of fibres; the one longitudinal, the other circular, cutting the longitudinal at right angles: the longitudinal are tendinous, and elastic; the circular are muscular, or move, like sphincters, which compress the circular are over the longitudinal, and embrace, or gird them round; the former, we have already observed, are elastic; and their elasticity opposes the compression of the latter. From this opposition, or resistance, arises a reciprocal action, and reaction, which is the alternative grinding force required.

To such an account for *digestion* from a ferment, those philosophers object, that *digestion* is a dissolution; so that to prepare the matters for this dissolution, they must be softened; that the proper effect of acid ferments, is to grow, or tear the hardest matters, and to soften the softer, to thicken the fluid, fix the fat, and coagulate the milk; consequently, that an acid ferment should rather impede, than promote, *digestion*. Add, that, beside the force to grind the juices, and the vessels to compress them, there are likewise liquors to dilute and temper them; viz. the saliva, and stomach-liquor; and mineral matters, which the stomach-liquor cannot dissolve, are found to be worn and polished, after having stayed some time in the stomach. Now, polishing is the effect of triture, or grinding, not of corrosion; accordingly we find pelicans, or balls of hair, or threads, in the stomachs of cattle, very smooth and shining, and far from having any marks of corrosion.

The authors who are for the trituration, require three things for *digestion* to proceed: a liquor to wet and dilute the food, which they find in the saliva and stomach-liquor; a vessel, which is the stomach; and a moving power to grind, which they imagine to have found in the muscles of the stomach, diaphragm, and abdomen. The moving force in the muscles of the stomach they maintain to be equivalent to the weight of 248733 pounds; and the force of the stomach, alone, to a weight of 12051 pound; a power more than equal to that of one of the heaviest mill-stones. See *Traité de la Digestion*, par M. Hecquet.

Borelli, on the footing of the equilibrium of fluids, has demonstrated, that the force of the flexor of the last articulation of the thumb is equal to 3720 pounds; whence Pitcairn deduces, that the force of the fibres of the stomach is equal to 12051, and that of the diaphragm, and muscles of the lower venter, to 248733 pounds. His way of estimating is this: the flexor only weighs 122 grains, and yet may sustain 3720 pounds; consequently, the fibres of the stomach, weighing 8 ounces, and the diaphragm, with the muscles of the lower venter, weighing together 8223 grains, have the force above mentioned. But this argumentation seems founded on a mistake; for it is not in virtue of its weight of 122 grains, that the flexor muscle is equivalent to 3720 pounds; besides that it would follow hence, that the heavier the muscles of the stomach, diaphragm, and abdomen, are, the more force they would have; and, consequently, the more easy and expeditious would the *digestion* be, which is false.

The patrons of this system compare the brain to the arbor, or tower, of a press; the heart to a piston; the lungs, to bellows; the mouth, to a mill-flower; or a pestle; the stomach, to a press; and the intestines, to a receiver, or vat. They contend, that Castellan, a physician of Messina, was the first of the moderns who expressly espoused the system of ferments; and that he was followed by Van Helmoort and Willis.

Not even the patrons of trituration are not perfectly agreed among themselves: Pitcairn will have it performed by a total contraction of the stomach; and M. Hecquet by a successive peristaltic, or vermicular, contraction.

Astruc, in his *traité De la Cause de la Digestion*, relates this system of trituration at large. He makes a strong opposition to the calculus which raises the moving force of the stomach, &c. so very high; the contraction of the fibres of the stomach, to compress the food, he shows, cannot exceed three ounces; and it is even *probatum* that he allows to much; that of the diaphragm, and abdomen, he computes at about four pounds. He observes, that Pitcairn, surprised, in all probability, with what he had asserted of this force, durst not pursue the proportion wherein his calculus was founded; and according to which, one of the forces would have been

found equivalent to 117083 pounds, and the other to 280734; which, together, make 367822 pounds.

The diaphragm, in its motion, has two powers; the one direct, which is that whereby its muscles draw from the centre towards the circumference; the other lateral, whereby it reits, or presses, on the stomach; the latter is very small, in comparison of the former. Now what seems to have deceived Pitcairn and Hecquet, is, their taking the direct for the lateral force; the contraction of the fibres, for their pressure on the stomach; and the same oversight they are guilty of in the muscles of the abdomen, whole pressure against the abdomen is only lateral. Add, that there are voracious animals without any diaphragm at all; as fishes, which require through their gills; and others, that have only a single membrane; as birds, in whom the muscles of the lower venter are very small and feeble, and in a situation that incapacitates them from acting at all on the stomach.

The membranes of the stomach being very soft, and having only a slender motion, seem very unfit for the office of a mill-stone. It is true, in certain fowls the stomach consists of a chole, compact, fleshy muscle, exceeding strong, so as to break little stones, and bits of glass; but to this it is *argued*, that it is no *digestion*, which in these animals is effected in the intestine; and the fluidness of our stomach, compared with the gizzard, or crop, of granivorous birds, does, on the contrary, furnish a very cogent argument against trituration. The gizzard is provided, on the outside, with four fleshy muscles, the tendons whereof meet in two opposite points; the inside is lined with a hard, thick, cartilaginous membrane, especially in the places where the tendons meet; by this mechanism, Nature plainly intimates the office of the gizzard to be the grinding of the grain by the friction of its parietes, or sides; whereas the membrane in the stomach of a man is exceedingly thin and fine, furnished with few fleshy fibres, covered with a tender, flexible, kind of villi, and the stomach itself is of a great capacity; and the stomach in rapacious birds, who devour huge pieces of raw flesh without chewing, is still a *spice* membrane. Lastly, on the foot of the system of trituration there seems no accounting for hunger, nausea, indigestion, cradities, &c.

In the system of trituration it seems impossible to explain why certain things easy to grind; e. g. cabbage-leaves cannot be *digested* in certain stomachs; which yet had no difficulty in *digesting* more hard and solid meats, as beef and mutton; whereas the difference of difficultness gives a natural and easy solution. Hydropic people continue to *digest*, notwithstanding the fibres of the stomach, as well as the rest of the body, are extremely relaxed, through the redundancy of moisture; and the total, prompt change of nature induced in foods, can be the effect of nothing else but fermentation; which even discovers itself by belching, &c. while it goes on. The iron, needles, pins, &c. sometimes found undissolved in the stomach, are no objection to the system of fermentation; it being notorious, that no solvent dissolves all bodies. In birds, which feed on grain, the fermentation is manifest; first in the crop, where the grain is prepared for *digestion*, by being macerated in a liquor like the saliva; and afterwards in the gizzard, where the *digestion* is perfected by a solvent poured into it by a conglomerate gland. But the thing is still more apparent in ruminating animals, which are provided with four stomachs; the two first whereof, though termed of a nervous membrane, make but little alteration in the aliment, for want of a ferment, or menbrum; so that it requires to be chewed again, and only becomes well *digested* in the fourth stomach, whither a solvent is poured from a conglomerate gland.

The partisans of the third opinion allow it incontestable, that there are acids in the stomach which mix with the foods, and act on them; and they hold, likewise, that their action is aided and promoted by the motion of the systole and diastole in the viscera; they add, that the acids produce a fermentation, and the oscillatory motion of the viscera a trituration; and that this *digestion* is the effect of fermentation and trituration at the same time. The doctrine of trituration was first propogated in the time of Hippocrates. An opinion was entertained by some physicians, of those times, that the stomach was only the receptacle of the solid or dry food; that these, after having been diluted, and broken in the mouth, were again broken more perfectly in the stomach; and that, by this means alone, they were converted into chyle; but that the drink, by reason of its liquidity, not being subject to be broken, went to the lungs, and not to the stomach, where, on account of its abundance, it would rather have prejudiced the *digestion* than have aided it. Hippocrates, we read, in the fourth book of *dicases*, vigorously opposed an opinion so contrary both

to reason and experience; and he was the more zealous in his opposition, because, as he informs us, the opinion had gained many partisans. However, it soon gave way to the reasoning of Hippocrates, and the system of trituration sunk with it. But Erasistratus revived it; and the doctrine, after having been supported for some time, fell into oblivion. Within the last century several have again endeavoured to recover it.

Dr. Picaud, M. de Reaumur, and many others, have espoused it. M. de Reaumur made many experiments both on granivorous and carnivorous birds, from which it appeared that the former digest their food by trituration, and the latter by solution in a proper fluid. Those that have gizzards were made to swallow short tubes of glass and tin; and when the fowls were killed, the tubes of glass were found split asunder lengthwise, and those of tin, either grooved from end to end, or flattened, or unrolled. But in order to show that this was done by the operation of grinding, without the aid of a dissolvent, M. Reaumur cut leaden tubes in moulds, whose shape could not be altered, and into these, left open at both ends, he introduced grains of barley, and bits of beef; and these, after remaining several hours, at different times, in the gizzards of fowls, were taken out, without any sensible alteration. In order to determine the mode of digestion in the stomachs of carnivorous birds, which are membranous, he caught a young buzzard, and made him swallow a tin tube, which might have been squeezed together by the pressure of a finger and thumb; but after twenty-four hours he threw it up, without any the least apparent mark of friction; whence he concluded, that the bird's stomach had little, if any, force of trituration. Having filled the tube with flesh, and fixed a proper quantity to each end, the buzzard was made to swallow it, and in twenty-four hours disgorged it, without the least injury to the thread melted at the ends; but the meat was covered with a kind of paste, and reduced to an eighth part of the original quantity. Other experiments were renewed with meat and bones; some of which were wholly dissolved, and others considerably reduced in quantity. Grain was tried in the same manner, without any visible change; the proper food of carnivorous birds being flesh.

Mr. John Hunter has lately made several experiments on the digestion of the stomach after death. Having observed that animals, or parts of animals, possessed of the living principle, when taken into the stomach, are not in the least affected by the powers of that viscus, whilst the living principle remains; he shews, that the stomach when deprived of the living principle, is itself capable of being digested either by the digestive powers of other stomachs, or by the remains of that power which it had of digesting other things. And hence it happens, that the stomachs of dead bodies are found dissolved at their greater extremity, from their own natural digestive powers, and not in consequence of any disease; appearances of this kind being most frequent in those who have died violent deaths. This digestive power of the stomach was further evident in fish, which swallow their food whole, and swallow fish much larger than the digesting part of the stomach can contain; the part lodged in the stomach was found more or less dissolved, whilst the part left in the oesophagus remained perfectly sound; and the digesting part of the stomach was itself, in many cases, actually dissolved.

From several facts of this kind, Mr. Hunter inferred, that the stomach, being dead, was no longer capable of resisting the power of that medium, which itself had formed for the digestion of its contents; and that digestion is performed not by any mechanical power, nor contractions of the stomach nor heart, but by something secreted in the coats of the stomach, which is thrown into its cavity, and here animates the food, or assimilates it to the nature of the blood. Mr. Hunter has found in the stomachs of all animals, to which his observations or experiments have extended, an acid, but not a strong one, in the juices contained in that viscus in a natural state. Phil. Trans. vol. xli. ser. 2. p. 447, &c.

Some suppose digestion owing to gentle heat and motion; by which the texture of the alimentary substance is changed in the bodies of animals; and then the constituent solid parts are endued with peculiar attractive powers of certain magnitudes, by which they draw out of the fluids moving through them, like parts in certain quantities, and thereby preserve their forms and just magnitudes. See Dr. Bryan Robinson of the Animal Oeconomy.

Be it as it will with each of the three systems, thus much we may venture to lay down from them all, as the real process of digestion; the end of this operation being to prepare the foods, so as that they may serve for nutrition, those foods must be considered from the time the man

takes them in; till, being converted into chyle, they mix with the blood, which conveys them into all parts of the body: the foods, then, we take, are either crude, as oysters, fruits, certain pulses, &c. or dressed, as flesh and fish, which are roasted, boiled, fried, &c. and seasoned a thousand divers ways with salt, pepper, and other spices, vinegar, wine, &c. This is done to heighten and enrich the taste, as much as to assist digestion.

Farther, there are some foods we swallow without chewing, as liquors; and others, which we break and comminute by chewing, as bread, flesh, &c. It is of these last we shall here speak, as undergoing more preparations, and more changes to fit them for nutrition, than the others.

The food, then, is first broke and divided by the teeth, and, at the same time, moistened with a liquid supplied by the salivary glands, and thus is formed into a kind of paste.

Thus prepared, it is passed through the oesophagus into the stomach, there to ferment. This fermentation is caused, 1. By the salivary and gastric juice, which is a ferment, and has the same effect on the aliment, that leaven, or yeast, has on paste. 2. By the heat of the stomach, viscera of the abdomen, and even excrements; which here have nearly the same effect on foods, as a dunghill has on matters laid by the chemists to digest therein. 3. By the remains of foods left adhering in the rugae, or folds of the stomach, and there turned sour and acrimonious. 4. By the agitation arising from the peristaltic motion, the compression of the muscles of the abdomen and diaphragm, and the continual pulsation of the neighbouring blood-vessels. 5. By the liquor which the repeated compression of those muscles occasions to drip from the glands of the stomach. And, 6. According to the sentiments of some modern physicians, by the air itself, which, being mixed, and embarrased in the aliments, dilates by the heat of the stomach, and separates the parts of the foods. This air, which once adhered to the substances composing our food, in a fixed state, does, in the moment of carboxication, resume its elasticity, and thus destroys the union of their minute particles. This elastic air is probably absorbed again by the alimentary mixture, and reduced to a fixed or non-elastic state, before the chyle enters the lacteals; though Dr. Black maintains, that the alimentary substances carry their fixed air into the blood, without throwing it off into an elastic state, during digestion; and he it is to far from believing that the aliment naturally ferments in the stomach, that he looks on such fermentation, when it does happen, to be the cause of many, and very dangerous diseases. These causes all contribute to attenuate and divide the food, so as to convert it into a cicatricious matter, called CHYLE.

From the stomach the chyle descends into the duodenum, and through the long tract of the smaller intestines, where it is farther perfected by the pancreatic juice; and the bile, which thin it, precipitates its grosser parts, and render it more fluid; and chiefly by the fermenting motion which still continues; the chyle, thus perfected and attenuated, enters the lacteal veins, fully charged with the subtle, active, antiseptic spirit, called fixed air, which convey it into the receptaculum chyli, where it is farther diluted by the lymph, which is brought thither in abundance; hence it arises into the thoracic duct, and enters the subclavian vein; where, being taken up by the ascending cava, it is poured into the right ventricle of the heart. The chyle, thus mixing with the blood, communicates its intestine motion to it, and thus prevents the natural tendency of the fluids to putrefaction; and the blood, by its volatile and exalted parts, together with the saline and mucous parts of the air, facilitates, and gives it its last perfection. Then the digestion is finished, and the foods being, by so many changes, rendered the immediate matter of nutrition, are carried by the blood into all parts of the body, to repair and fill the vacancies of such as are continually dissipating and exhaling, or even to add new ones.

As to the grosser parts of the foods, separated from the chyle by the bile and pancreatic juice, they assume the colour of excrements, from the bile; and their rank smell they derive from the coarser sulphur thereof, and from the four and putrid ferment, that is lodged in the coecum, which, in a very short time, convert the alimentary remains into their own nature. These sulphurs, and salts of the excrements, together with their putrescent quality, serve, after they have passed through the intestines, and are arrived at the lumb, which is the rectum, to relaxate the muscles thereof, and dispose them to relax, and thus to appropiate nature of a necessity to discharge.

In particular cases, however, as in those of weak and relaxed habits, of pregnant women, whose stomachs, are

great part of the smaller intestines, are thrown out of their natural situation, and of persons who lead sedentary lives, the food is often detained for long in the first passages, as to pass on to the second or scottous stage of alimentary fermentation; and then it produces a very auferic acid, which, not being admitted by the lacteals, accumulates, and occasions four eruptions, heart-burning, vomiting, griping, or looseness, according to its quantity, degree of strength, and place where lodged. The four acrimony precipitates the alimentary mixture through the first stage of fermentation to the second, and prevents the food from yielding a nutritious chyle, which appears from a pale and languid disposition of those who are much afflicted with sourness in the stomach. This circumstance suggests one reason, why exercise, which agitates the viscera, and prevents the too long stay of the aliment in the first passages, and the aromatic gums and bitters, together with chalybeates, whose qualities are strengthening and stimulating, prove so very serviceable in all these cases. But if the aliment, either from its own very putrescent nature, or from its too long stay within the confines of the smaller intestines, should proceed to the third, or putrefactive stage of fermentation, it will become so offensive, as to occasion immediate efforts for throwing it off, or, in dangerous diseases, and even death. Macbide's Essay, p. 20, &c.

The separation of the urine from the blood may be deemed a part of perfect digestion; the design of such separation being to render the blood more pure and salubrious; and, of consequence, more fit for nutrition; which the salts, with which the urine abounds, greatly prevented. This separation is thus performed: the branches of the excremental arteries, which terminate in the glands, whereof the substance of the kidneys is composed, carry the blood thither; where a serosity is separated from the blood, by means of the pores in the glands of the kidneys; those pores representing the holes in a sieve, which only let pass those things as are of a less diameter than themselves. This serosity, called urine, is discharged hence into several little tubes, which joining in a kind of pyramid, yield their humour into the pelvis, whence it runs through the ureters into the bladder.

DIGESTION, in Chemistry, is a preparation of plants, minerals, metals, or other bodies, by putting them, with some proper fluid, in a vessel, and heating them gradually over a gentle fire, like the heat of an animal body. Digestion is ordinarily confounded with maceration; but the two things differ, in that there is heat required to digestion; whereas maceration is done in the cold. Digestion is usually performed with the addition of some menstruum suitable to the matter: thus roses and poppies heads are put to digest in oil, or water, to make unguents, or syrups; calcined lead, and ceruss, are digested in distilled vinegar, to make the magistery thereof, or the sal Saturni. Hence Dr. Friesen deines digestion to be the solution of bodies, made by menstria, with the assistance of fire.

The use of digestion in pharmacy, is to extract the more volatile particles, and mix them intimately with the menstria. To this end a gentle fire is commonly used, that the corporeals, which are most volatile, may separate, as it were, of their own accord; for a fierce fire forces out the feces, as well as the finer particles; and if it does not abate the strength of the liquor, as is often the case, it will not fall off spoiling its clearness.

In some cases digestion is used to produce a change in a single body, as in mere precipitation; in others to promote solutions, or other combinations: as of well-calced, dry fixed alkali, with rectified spirit of wine, which digested together in a matras, with a gentle sand-bath heat, becomes an alkaline tincture of a yellow reddish colour, called tincture of salt of tartar. CIRCULATION is a mode of digestion. The vessels generally used for this purpose are matrasses, or Florence flasks, either of which may be easily converted into circulatory vessels. The operation is generally performed in a sand-bath, by which the degrees of heat may be regulated according to the intention of the operator. This heat should never rise so as to make the matter boil. Digestion is used for making tinctures, wines, elixirs, &c.

The chemists of late years have too much given into the more elaborate and forced processes, and neglected the more natural and easy ones. Among these latter is digestion; a process so easy, that it requires scarce any quantity in the operator but patience, and yet will do such things as all the elaborate processes of that art can never arrive at without it. There is scarce a process that has more puzzled the chemists of an age or two ago, than the volatilizing salt of tartar; yet Langelot assures us, that after using all the caution in the common processes that an exact desire of success could inspire him with, he failed in them all; till trying the effect of a long di-

gestion, he succeeded so well in the first attempt, that he converted almost the whole salt into a pure white volatile substance, leaving only a few insipid earthy faces behind. Another great use of digestion is the duly preparing of the effluents of mineral sulphurs; the stony sea-plants, which greatly resemble the nature of fossils, are also better treated by this process than by any other. Turbated spirit of wine, receives a very high tincture from red coral, after a long digestion, in any distilled vegetable oil, though it will not in the common way be at all coloured by it. Phil. Trans. N° 57. See COCAU.

DIGESTION, in Surgery, expresses a disposition in abscesses to ripen, and come to suppuration.

Tumors, arising on the parotides of children, are of easy digestion; they ripen in a little time. Dionis.

DIGESTION is also used for maturation, or that state of a disease wherein the morbid matter is to be changed in bulk, figure, cohesion, mobility, &c. by the use of proper medicines, or even by the force of nature, as to be less noxious and hurtful, and, consequently, to abate the violence of the distempor.

The Greeks call it *μαρασις*. The matter of the disease so far digested, as to become next akin to salubrious, or healthy matter, is said to be *resoluted*.

DIGESTIVE faculty. The ancient philosophers admitted a digestive faculty, or quality, in the human body; as not knowing how otherwise to account for the act of digestion.

DIGESTIVE is also used, in Medicine, for such remedies as strengthen and increase the tone of the stomach, and assist in the digestion of foods. To this class belong all bismarics and strengtheners, or corroborants.

DIGESTIVE, in Surgery, denotes a sort of unguent, plaster, or the like, that ripens and prepsares the matter of wounds, &c. for suppuration.

The common digestive is composed of turpentine, yolk of eggs, oil of St. John's wort, unguentum basilicum, and tincture of aloes.

The wound must be dressed the first day with a digestive, to bring it to suppuration.

DIGESTOR, or **DIGESTER**, an artificial means, or instrument, serving to digest, or dissolve meats out of the stomach, by a way analogous to that of animal digestion. Mr. Leigh, in the Philosophical Transactions, gives us an artificial digester, to illustrate the natural one; it is prepared from spirit of sulphur, spirit of hartshorn, the chyle of a dog, and its saliva. A piece of veal, mutton, beef, or the like, of the bigness of a nut, being put in a dram of this preparation, and set on a digressing furnace two hours, it drew from the flesh a juice, that had the colour and taste of chyle, and left the meat light, dry, and insipid.

Dr. Havers prepares a digester of oil of turpentine mixed with oil of vitriol; in which, raw flesh, and crumbs of bread being put, and the whole committed for four hours to digest in balneo Mariæ, the meat is found dissolved, and the whole together forms a thickish pulp; hence, those authors, each of them, conclude the food in the stomach to be digested by some such menstria.

But the most celebrated digester, is an instrument of that name, invented by Papin, the effect whereof bears a more near resemblance to the operation of the stomach. It is a sort of vessel, wherein meat being put, together with so much water as serves exactly to fill it, a lid is screwed close on, so as to admit of no external air. Then, by the application of two or three lighted charcoals, or even a single small lamp-flame, the meat is in a few minutes (six or eight) reduced into a perfect pulp, or rather liquor. By a little increase of the fire, or the addition of a few minutes in time, the hardest bones themselves are brought into a pulp or jelly. The effect is accounted for from the strict closure of the engine, which excluding the intrusion, or escape, of air, the succions occasioned by the expansions and contractions of the air included in the flesh, are equable and strong, and so resolve the whole into one seemingly homogeneous body, and mix the aqueous, saline, oleous, and other particles, so strongly together, as scarce to separate, but while hot, to appear one liquor, and when cold, jelly of a strength proportionate to the quantity of flesh, or bones, dissolved in the water.

This experiment seems to hold a close analogy with the operation of the stomach. For though the stomach doth not ordinarily dissolve, either so strongly, or so quick a yet in proportion to its heat and construction, Dr. Drake takes it to do the same thing; thereby breaking, and resolving into small, the bodies which it included, so mixed, *inter minima*, with its humours. These, thus reduced into a floor, and intimately mixed with the liquids of the drink, and juices of the stomach, compose that lactescent liquor, called *chyle*, or *chyme*. See CHYLE.

DIGGING, in *Mineralogy*, a term appropriated by the miners to express that penetrating into the earth, where they have the ore before them, and every stroke of the tools turns to account.

They appropriated the word to this sense, expressing the random openings, which they make in search of mines, by the word *batting*, or *off-batting*. See the article *TRAINING OF MINES*.

When the cilly-hatches have been opened so long, that the orifice of the mine or load is found, the opening which has led to it, loses its name of cilly-hatch, and is called a shaft or metal-hatch; this is to be sunk down about a fathom, and then they leave a square space, called a *shamble*, and so continue sinking from cast to cast; that is, as high as a man can conveniently throw up the ore with a shovel, till the load is found to grow small, or else to degenerate into some unprofitable substance, or weed, as they metaphorically express it. The degeneracy of the ore is soon perceived, by the finding of mundic or marcasite growing more plentifully among it. This is a sulphureous mineral, of a yellow, whitish, or greenish colour, and is very troublesome to the Cornish miners. The other unprofitable substances found in the place of the ore, or mixed in large quantities with it, where it degenerates, are daze, which is white, black, or yellowish; *iron mould*, which is black or rusty; *caul*, which is red; *glister*, which is blood-red, or black; is also another degeneracy of the ore. These are the common names given by the miners to various fossils, and these are the marks by which they know the vein is almost exhausted in that part, and will not long be worth digging.

In this case, they begin to drive either east or west, as the goodness of the land, or the convenience of the hill, unite. The drift or opening, on this occasion, is three feet over, and seven feet high, so that a man may conveniently stand and work; but in case the land is not broad enough of itself, as some are scarce half a foot, then they break down the deads first on the north side of the land, for the greater convenience of the right arm in working, and then they begin to rip the load itself. By the term deads, they mean that part of the shelf, which contains no metal, but encloses the load or vein as a wall between two rocks.

The instruments commonly used in mines with us, and that serve for ripping the lands, are the *berle*, or, as it is called in Cornwall, the *tabler*. This is an instrument of eight or ten pounds weight, well fleeced and sharpened at each end, ending in a point each way, and having a hole in the middle; this will last half a year, but must be new sharpened every fortnight. The second instrument is a *slodge*; this is usually made from ten to twenty pounds weight; and will last seven years, if new ordered once in three or four months. Beside these, they have *gaddis* or wedges; these are of about two pounds weight; they are made four-square, and well fleeced at the point, and they must have ladders and wheel-barrows to carry the deads and the ore out of the adits to the shambles. The general proportion of the workmen in Cornwall, is this: two shovel-men and three beetle-men in a drift; these are as many as the drift will contain without standing in one another's way. The beetle-men rip the deads and the ore, and the shovel-men carry it off and land it, by casting it up from one of the shambles to another all the way up. In some places they have the trouble of this casting it to the shambles by a winder and two buckets: these are so contrived, that one goes up as the other comes down, and they are filled and emptied with great ease. Phil. Trans. N° 69.

DIGIT, DIGITUS, in *Anatomy*. See *FINGER*.

DIGIT, in *Astronomy*, is the measure whereby we estimate eclipses: amounting to the twelfth part of the diameter of the luminary eclipsed.

The diameter of the body, or disk, of the sun or moon, is divided into twelve parts, called *digits*; and an eclipse is said to be of ten *digits*, when ten of those parts are hid.

These *digits*, Wolfius, and some others, call *digitis æquidistantibus*.

DIGIT, in *Arithmetic*, signifies an integer, or number, under ten; as 1, 2, 3, 4, 5, 6, 7, 8, 9.

DIGIT is also a measure taken from the breadth of the finger. A *digit* is properly three-fourths of an inch, and equivalent to four grains of barley, laid breadth-wise, so as to touch each other.

DIGITALIS, in *Botany*. See *FOX-GLOVE*.

DIGITATED LEAF, among *Botanists*. See *LEAF*.

DIGITUS Veneris, *Veneris finger*, in *Botany*, a name by which some authors have called the nymphæa, or water-lily.

DIGLYPH, from *dis*, twice, and *glyphe*, I engrave, a kind of imperfect triplyph, console, or the like, with only

two channels, or engraving, instead of three. See *TRIPLYPH*.

DIGNITARY, in the *Canon Law*, a person who holds a *dignity*, that is a benefice, which gives him some pre-eminence in the choir, above mere priests and canons. Such is a dean, and archdeacon; though the word is now abusively applied to a mere prebendary, or canon.

Dignities are sometimes simple, sometimes with cure of souls, and sometimes with jurisdiction and administration of sacred things. The canonists even define *dignity*, *administratio cum jurisdictione & potestate conjuncta*. If the *dignity* have no contentious, or exterior jurisdiction, it is a simple parsonage, and only gives pre-eminence. See *BENEFICE*, *PARSONAGE*, &c.

Of *dignities*, including prebends, Camden reckons in England, 544 in number.

DIGNITY, a quality that denotes a man (*dignus*) worthy.

DIGNITY, in its most usual acceptation, signifies honour and authority, reputation, &c. and *dignity* may be divided into superior and inferior; as the titles of duke, earl, baron, &c. are the highest names of *dignity*; and those of baronet, knight, serjeant at law, &c. the lowest. Nobility only can give so high a name of *dignity*, as to supply the want of a surname in legal proceedings; and as the omission of a name of *dignity* may be pleaded in abatement of a writ, &c. so it may be where a peer who has more than one name of *dignity*, is not named by the most noble. 2 Hawk. P. C. 135, 236. No temporal *dignity* of any foreign nation can give a man a higher title than that of equino. 2 Inst. 657.

DIGNITY, in *Oratory*, is one of the three parts of general elocution; and consists in the right use of TROPHES and FIGURES. See *COMPOSITION* and *ELEGANCE*.

DIGRESSION, in *Oratory*, is defined by Quintilian, agreeably to the etymology of the word, to be, a going off from the subject we are upon to some different thing, which, however, may be of service to it. Inst. Or. lib. iv. cap. 3.

Digression is not a necessary part of a discourse, though it may sometimes be convenient on several accounts; as where a subject is of itself flat and dry, and requires close attention; in this case it is of use to relieve the mind by something agreeable and entertaining. But as it should never be introduced without sufficient reason, it should never be too frequent, nor too long. Ward's Or. vol. i. p. 283, &c.

DIGYNIA, in the Linnæan system of *Botany*, an order of plants, or a subdivision in most of the classes established by Linnæus, denoting that the plants have two styles. The term is derived from *dis*, double, and *gynæ*, wife. See *FRUCTIFICATION*, and *SEXUAL SYSTEM*. See Tab. II. of *Botany*.

DIHÉLIOS, from *dis*, through, and *hélis*, sun, in the *Elliptical Astronomy*, a name which Kepler gives to that ordinate of the ellipsis, which passes through the focus, wherein the sun is supposed to be placed.

DII PATRII, among the Romans, were the three supreme deities, Jupiter, Juno, and Minerva. They were first received over all the East, and afterwards, successively, in Greece and Italy. They are described as *indigiti* by Virgil, Georg. i. ver. 499. and as *indigiti* by Juvenal, Sat. iii. ver. 145.

DIJAMBUS, in *Poetry*, the foot of a Latin verse of four syllables; it is compounded of two iambs, as *se-cun-dus*.

DIIPOLIA, *Διιπολία*, in *Antiquity*, an Athenian festival, celebrated in honour of Jupiter Politeus, or protector of the city. For the ceremonies observed at this solemnity, see Potter's *Archæol. Græc.* lib. ii. c. 20. tom. i. p. 381.

DIKE, a ditch, or drain, made for the passage of waters.

The word seems formed from the verb *to dig*; though others choose to derive it from the Dutch, *dijk*, a dam, sea-bank, or wall.

DIKE, or **DIKE**, also denotes a work of loose, timber, or fascines, raised to oppose the entrance, or passage of the waters of the sea, a river, lake, or the like.

The word comes from the Flemish *dijk*, or *dike*; a heap of earth to bound, or stem the water. Junius and Menage take the Flemish to have borrowed their word from the Greek *ταχυς*, wall. Guichard derives it from the Hebrew *dayshub*.

These *dikes* are usually elevations of earth, with hurdles or stakes, stones, and other matters.

The *dike* of Rochelle is made with vessels fastened to the bottom. The *dikes* of Holland are frequently broke through, and large tracts of land are then drowned.

DILAPIDATION, a wasteful destroying, or letting buildings, especially parsonage houses, run to ruin and decay, for want of necessary reparation.

An action lies for *dilapidation*, either in the spiritual court by the canon law, or in the courts of common law; and it may be brought by the successor against the predecessor, if living, or, if dead, against his executors.

The money recovered for *dilatation*, by 14 Eliz. 11, must be employed in the repair of the same houses, within two years, on penalty of forfeiting double the value to the crown.

DILATATION, in *Physics*, a motion of the parts of a body, whereby it expands or opens itself so as to occupy a greater space.

The generality of authors confound *dilatation* with rarefaction; but the more accurate, especially foreigners, distinguish between them; defining *dilatation* to be the expansion of a body, into a greater bulk, by its own elastic power; and rarefaction, the like expansion produced by means of heat.

The moderns have observed, that bodies, which, after being compressed, and again left at liberty, restore themselves perfectly, do endeavour to *dilate* themselves with the same force whereby they are compressed; and accordingly they sustain a force, and raise a weight equal to that whereby they are compressed.

Again, bodies, in *dilating* by their elastic power, exert a greater force at the beginning of their *dilatation*, than towards the end; as being at first more compressed; and the greater the compression the greater the elastic power, and endeavour to *dilate*. So that these three, the compressing power, the compression, and the elastic power, are always equal.

Again, the motion, whereby compressed bodies restore themselves, is usually accelerated: thus, when compressed air begins to restore itself, and *dilate* into a greater space, it is still compressed; and consequently, a new impetus is impressed thereon, from the *dilatative* cause; and the former remaining, with the increase of the cause, the effect, that is, the motion and velocity, must be increased likewise: thus an arrow shot from a bow does not quit the string, till after that perfectly restored to its natural state; nor does the arrow move a whit swifter than the string; and if the string, before it have perfectly restored itself to its right line, be stopped, the arrow will not go its full length; which is a proof, that it is continually acquiring a new impetus from the string. And since projectiles, at the beginning of their motion, are little or nothing retarded, but rather accelerated, it is evident, that the motion of a string restoring itself, is likewise accelerated. Indeed, it may happen, that where the compression is only partial, the motion of *dilatation* shall not be accelerated, but retarded; as is evident in the compression of a sponge, soft bread, wax, &c.

DILATATION, in *Medicine*, &c. denotes the laying open any orifice, or the lips of a wound, wider; or the extension of any vessel, or the like.

This is done by an instrument called a *dilatatorium*.

DILATORII *pessimi* *artibus*, in *Anatomy*, a name given by Heister and some others, to what is supposed to be a peculiar muscle by many, and called also *levator sexti costæ*, and by some other names, though it is really only a process of the sphincter ani running into the perineum. See SPHINCTER.

DILATATOIRES *ale nasi*, in *Anatomy*, a pair of muscles common to the *ale nasi*, and upper lip.

They arise thin, broad, and fleshy, from the cheek-bones under the orbits of the eyes, and descend obliquely with a two-fold order of fleshy fibres in each muscle; which partly terminate in the upper lip, and partly in the *ale nasi*. They draw the *ale* from each other, and widen the external openings of the nostrils.

DILATORY *pias*, in *Law*, are such as are put in merely for delay; and there may be a demurrer to a *dilatory plea*, or the defendant shall be ordered to plead better, &c. 6 Mod. The truth of *dilatory pleas* is to be made out by affidavit of the fact, &c. by stat. 4 and 5 Anne. See PLEAS.

DILE, in *Botany*, a name by which some authors have called the liris or woad. Ger. Emac. Ind. 2.

DILEMMA, *ἀδύναμα*, in *Logic*, an argument consisting of two, or more propositions, so disposed, that grant which you will of them, you will be pressed by the conclusion.

The word is formed from the Greek *δί*, bis, twice, and *λέμμα*, sumptio.

A *dilemma* is an argument consisting of two contrary parts, or sides, either of which catches the adversary. And hence it is also called *σπλιγγισμὸς ἐκρωτιστός*, a *harked syllogism*, its horns being so disposed, that if you avoid the one, you run upon the other.

It is also called *ἐκρωτισμὸς*, by reason that as the crocodile leads such as follow it, into the water, and pursues such as fly it, to destroy them; so, whatever the adversary either affirms, or denies, in this kind of syllogism, is turned to his disadvantage.

For an example: A philosopher once dissuaded a man from marrying, by this argument: Either the woman you marry will be handsome, or ugly; if handsome, she will give you jealousy; if ugly, displeasure.

Cicero uses this fine *dilemma*, to prove, that all pain is to be borne with patience: *autem dicitur aut sit dolens, aut laetus; si laetus, facile ferat; si dolens, certe brevis fuerit dolor*.

The same orator, by another *dilemma*, proves that no meffengers shall be sent to Anthony: *legatis dicitur, si ut deprecator, centumviri: si ut imperator, non audiet*.

Nor must we here omit that beautiful *dilemma* of Tertullian whereby he clears the Christians, and accuses Trajan, who had forbid the seeking them out, and yet ordered them to be punished when found: *Utrumque necessitate confasum! negat imperatorem, et innocentem; et mandant persequi, et nocentes; perit et laetus, diffundit et amandavit! quid temeritatem casus circumvenit? si dicitur, carum non est inquiri? si non inquiri, carum non est obsequi?*

For a *dilemma* to be legitimate, there are two things required: 1. A full enumeration of parts; thus that of Aristippus above mentioned, whereby he diffuses from marriage, is invalid, as being defective in the enumeration; there being a middle degree, or form, between *handfome* and *ugly*.

2. That the *dilemma* press the adversary alone, and that the person who makes it be not liable to have it retorted upon him. This was the case in that celebrated *dilemma* of the sophist Protagoras, which the areopagites, with all their wisdom, were not able to resolve.

A youth named Evathlus, engaged with Protagoras, to learn dialectics, upon condition, that he should pay him a large sum of money, the first cause he pleaded, in case he gained the fame. Evathlus, when fully instructed, refusing to pay the condition, Protagoras brings his action, arguing thus: You must pay the money, however the cause go; for if I gain, you must pay in consequence of the sentence, as being cast in the cause; and if you gain it, you must pay it in pursuance of our covenant. Nay, retorts Evathlus, which way soever the cause go, you will have nothing: for if I prevail, the sentence gives it, that nothing is due to you; and if I lose, then there is nothing due by the covenant.

After the like manner, an ancient priestess dissuading her son from buxanting the people, by this *dilemma*, *nam si injusta fueris*, says she, *habebis Deum iratum: si vero iusta, iratus habebis homines*: the youth thus returned the *dilemma* on his mother: *immo, fave he, respicit ut populum verba facere, nam si iusta dixeris, Deum amabunt; si injusta, homines*.

DILICTUM, a term used by Agricola, to express a brine, made by pouring water upon sand, stones, earth, &c. that had been before strongly impregnated with salt: from this brine, a salt, for the use of the table, was made by evaporation in his time, and is still so in many parts of the world. At Junthal, in Germany, they have a salt work of this kind, where they make at the rate of eight hundred loads of salt in a week, each load weighing four hundred weight.

DILIGENZA, in the *Italian* *Mosse*, is used for a soft or sweet manner of singing or playing.

DILL, *Anethum*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: it is an umbelliferous plant, with many umbels, which are uniform; the flowers have five spear-shaped petals; under the flower is situated the germin, which afterward becomes two compressed seeds, having borders. We have but one species of this plant, which is the common *dill*.

This plant, both in root, stalk, and leaf, very much resembles common fennel, excepting that it seldom grows so tall, or is so much branched; the whole plant is of a very strong scent, less pleasant than fennel. It flowers and seeds in July and August; the leaves and seeds are used. The official preparations of this plant, are a water, oil, and ether; for which, see ANETHUM.

DILLENIA, in *Botany*, the name of a genus of plants, of the *polyandria polygynia* class; the characters of which are these: the perianthium is composed of five leaves, which are large, roundish, hollow, and of a coriaceous texture, and remain when the flower is fallen; the flower is composed of five roundish hollow petals; these also are large, and of a coriaceous texture. The stamina are numerous filaments forming a sort of globe; the anthers are oblong and creck. The germina are about twenty in number; they are of an oval oblong figure, and pointed; they are somewhat compressed, and adhering together by their inner surfaces; there are no styles. The stigma are large and pointed, and are disposed in form of a star; the fruit is roundish, and is covered with a number of capsules, divided by so many furrows. The seeds are numerous and small.

DILLOUGHING. See TIN.

DILUTE. To *dilate* a body, is to render it liquid; or, if it were liquid before, to render it more so, by the addition of a thinner thereto.

Those things thus added, are called *diluents*, or *dilutors*; such are common whey, pissina, and juleps, which respect

respect of the blood in a state of viscosity are thinner, and therefore are said to thin, or dilate it. Flour must be well diluted, to make it into paste. Ochre is diluted with oil, to paint beams, doors, &c.

DIMACHÆA, from *δίς*, double, and *μάχη*, I fight, in Antiquity, a kind of horsemanship, first instituted by Alexander. Their armour was lighter than that of the infantry, and at the same time heavier than that used by horsemanship, so that they could act as horse or foot as occasion required.

DIMACHÆRUS, *Διμάχηρος*, from *δίς*, and *μάχηρα*, sword, in Antiquity, a gladiator who fought with two swords.

DIMETER. See IAMBIC.

DIMENSION, the extension of a body, considered as measurable.

Hence, as we conceive a body extended, and measurable in length, breadth, and depth, we conceive a *trine dimension*, viz. length, breadth, and thickness. The first called a *line*, the second a *surface*, the third a *solid*.

DIMENSION is particularly used with regard to the powers of the roots, or values of the unknown quantities of equations, which are called the *dimensions* of those roots.

See EQUATION and ROOT.

Thus in a simple equation, the unknown quantity is only of one dimension, as $x = a + b$. In a quadratic equation it is of two dimensions, as $x^2 = a^2 + b^2$. In a cubic, of three, as $x^3 = a^3 - b^3$, &c.

DIMETIENT, in Geometry, is sometimes used for diameter.

DIMINISHED interval. See INTERVAL.

DIMINISHED second is a semitone major, lessened by a semitone minor. See INTERVAL and SECOND.

DIMINISHED third, by some called *disjunct third*, is properly a third minor lessened by a semitone minor. But among practical musicians, it commonly signifies an interval equal to two semitones major. And this they confound with the former; but there is a difference between them, equal to the difference between a tone-major and minor, that is, a comma. The first mentioned of these *diminished thirds* will be expressed by $\frac{2}{3} \times \frac{2}{3} = \frac{4}{9}$; and is equal to the tone-major and enharmonic diatonic; for $\frac{2}{3} \times \frac{2}{3} = \frac{4}{9} \times \frac{3}{2} = \frac{2}{3}$. The second *diminished third* will be expressed by $\frac{2}{3} \times \frac{2}{3} = \frac{4}{9} \times \frac{1}{2} = \frac{2}{9}$, which is a comma less than the former. See the table in the article INTERVAL.

DIMINISHED fourth. See the table in the article INTERVAL.

The *diminished fourth* often occurs in practice, as from C to G $\sharp$ descending; and sometimes, though more rarely, from G $\sharp$ to C ascending.

DIMINISHED fifth, in Music, is less than the true fifth by a semitone minor, and is therefore equal to two lesser thirds.

Practitioners often confound the *diminished fifth* with the semi-diatone, or false fifth, which is a comma less. See INTERVAL.

DIMINISHED sixth. This interval, according to Ozanam, contains two tones and three semitones major; or a fourth and *diminished third*; or a *diminished fourth* and third minor. Thus from C $\sharp$ to A $\flat$ is a *diminished sixth*.

But as there are two *diminished thirds*, so there may be as many *diminished sixths*; these being the complements of the former to the octave. One of these *diminished sixths* will be expressed by $\frac{2}{3} \times \frac{2}{3} = \frac{4}{9} \times \frac{3}{2} = \frac{2}{3}$; and this is a semitone major more than the semi-diatone; the other *diminished sixth* will be $\frac{2}{3} \times \frac{2}{3} = \frac{4}{9} \times \frac{1}{2} = \frac{2}{9}$, which is a semitone minor less than the flat sixth. Practitioners confound these two; and, in effect, in temperate scales they coincide, as do all other intervals differing only by a comma. See TEMPERAMENT.

DIMINISHED seventh is of two kinds, differing by a comma. See the table in the article INTERVAL.

That *diminished seventh*, which is in the complement of the superfluous second to the octave, is the only one in use. It is a semitone major more than the sixth minor, as from C $\sharp$ to B $\flat$.

DIMINISHED octave, is a semi-tone minor, less than the octave, as from C to c $\flat$. It occurs sometimes in the basses of instrumental pieces of music. See INTERVAL.

DIMINUTION, in Architecture, a contraction of the upper part of a column, whereby its diameter is made less than that of the lower part. See Tab. Archit. fig. 36.

To attain those two important points in architecture, strength, and the appearance of strength, all architects have made their columns lesser above than below, which is called their *diminution*. Some have likewise made them a little bigger towards the middle than at the bottom, which is called their swelling. The Gothic architects, indeed, observe neither *diminution* nor swelling; their columns are perfectly cylindrical; for which reason they are properly called pillars, in contradistinction to columns.

The *diminution* generally commences from one third of the height of the column. Some make it begin from the very basis, and hold tapering to the capital; but that has not so good an effect. Vitruvius would have the *diminution* of columns differ according to their height, and not according to their diameter: thus, a column of fifteen feet high, he diminishes a sixth part of its diameter; and another of fifty feet only an eighth part; but we do not find this rule observed in the antique. The difference of orders, M. Perrault observes, does not infer a difference of *diminution*, there being small and great *diminutions* in different works of the same order; excepting, however, the Tuscan, which Vitruvius diminishes by a fourth part, though Vignola only makes it a fifth, and the Trajan column a ninth. The *diminution* are very differently adjusted in the different antique buildings, as well as by the different modern authors. For the method of diminishing a column, see COLUMN.

DIMINUTION, in Heraldry, a term used by Latin writers for what we more usually call *difference*, and the French *brisure*. See DIFFERENCE.

DIMINUTION, in Law, is where the plaintiff or defendant in a writ of error alleges to the court, that part of the record remains in the inferior court not certified, and therefore prays that it may be certified by certiorari. *Diminution* cannot be alleged of what is fully certified, but of something that is wanting, as the want of an original, or a warrant of attorney.

DIMINUTION, in Music, is when there are a number of words which are to make tones, and several hasty motions in the space of a cadence; several quavers, and semiquavers, corresponding to a crotchet, or minim.

DIMINUTION, in Rhetoric, the augmenting and exaggerating what you have to say, by an expression that seems to weaken and diminish it.

As for instance, when a man says, with a certain tone, This woman is not ugly; meaning, she is very handsome.

Some authors take *diminution* in a stricter sense, viz. for saying less than a man really means; as, You are not, indeed, to be commended; where a greater reproach is secretly meant.

DIMINUTIVE, in Grammar, a word formed from some other, to soften or diminish the force and effect thereof; or to signify a thing that is little in its kind. Thus *cellule* is a diminutive of cell; *globule*, of globe; *hillock*, of hill, &c.

The Italians abound in *diminutives*, every author being at liberty to make as many as he pleases. The French are a good deal more reserved in that respect, though their old authors were every whit as licentious as the Italians, witness Belleau, &c.

In English we have very few; not that, as some have said of the French, our language is hard, and incapable of the softest expressions, but because we lay all our tenderness in our sentiments; or rather, our language is tender, like a person of discretion, who always speaks sense, even in speaking of his passion.

In Latin, Italian, English, and most other tongues, *diminutives* are formed from primitives, by the addition of a few letters, or syllables: in French, the case is frequently otherwise, the *diminutive* being sometimes shorter than the primitive, sometimes of the same length.

They have a pleasing effect in that celebrated address of Adrian to his departing soul, which begins,

*Animulo, vogula, blandula
Hesper comesque corporis, &c.*

Some grammarians call *at least* a *diminutive* conjunction, as serving to lessen or diminish the force of what went before.

DISSOLVING Letter, *Littera Dimissoria*, in the Canon Law, a letter given by a bishop to a candidate for holy orders, having a title in his diocese, directed to some other bishop, and giving leave for the bearer to be ordained by him.

When a person produces letters of ordination, or tonsure, conferred by any other than his own diocesan, he must at the same time produce the letters *dimissory*, given by his own bishop, on pain of nullity.

Littera dimissory cannot be given by the chapter, *sede vacante*; this being deemed an act of voluntary jurisdiction, which ought to be reserved to the successor.

DIMNESS of sight, in Farriery, a disorder in horses, proceeding from blood-throten eyes. If the ball of the eye be found, the cure is effected by keeping the horse warm, with a hood of linen cloth fitted to his head, and anointing the eye-lids twice a day with a composition of sugar-candy, honey, and white rose-water. In two or three days the eyes will be well, after which the creature should be bled.

In this disorder the bladders on any part of the eye ought

by no means to be clipped, or meddled with. See **SIGHT**.

DIMERITÆ, a name given to the Apollinarists, who at first held, that the word only assumed a human body, without taking a reasonable soul like ours; but being at length convinced by formal texts of Scripture, they allowed, that he did assume a soul, but without understanding; the word supplying the want of that faculty. From this way of separating the understanding from the soul, they became denominated *dimeritæ*, q. d. *dividers, separatori*, of *anima* and *corpore*, *I divide*.

DIMORPHOTHECA, in *Botany*, a name given by Vailant to a genus of plants, which Linnaeus makes the same with the *calendula*. See **MARYGOLD**.

DING, in *Cuvenner*, a name which the Siamese give in general to all sorts of weights.

DINNAGE. See **DUNNAGE**.

DINNER, the great meal, or that taken about the middle of the day.

The word is formed from the French *dîner*, which DuCange derives from the barbarous Latin *dināre*. Henry Stephens derives it from the Greek *δινειν*; and will have it wrote *dinner*. Menage deduces it from the Italian *dināre*, *to dine*; and that from the Latin *dinare*, *to leave off work*.

The grand Tartar, emperor of China, after he has *dined*, makes publication by his heralds, that he gives leave for all the other kings and potentates of the earth, to go to *dinner*; as if they waited for his leave. In the general, it is agreed to be the most salutary to make a spare supper, and to eat the more plentifully at *dinner*, especially for tender, valetudinary people. This is the sentiment of the Schola Salernitana.

*Ex magna cena stomachi fit maxima parva:
Ut si nolle levis, fit tibi cena brevis.*

Yet Bernardinus Paternus, an eminent Italian physician, maintains the contrary, in a treatise expressly on the subject.

The Romans, we are assured, never minded *dinner*; but deferred their good cheer to the evening, which they made their grand meal.

DINUS, in *Medicine*, according to some, is the name of a disease, called more usually **VENUSITICO**.

DIOCALLIA, in *Botany*, a name by which Apuleius and some other authors have called the common sweet chamomile.

DIOCESE, or **DIOCESS**, the circuit or extent of the jurisdiction of a bishop. See **BISHOP**.

The word is formed from the Greek *διοικησις*, government, administration, formed of *διοικω*, which the ancient glossaries render *administra*, *moderor*, *regina*; hence *διοικησις* the *moderation*, *administration*, or *government* of a city.

DIOCESE is also used, in *Ancient Authors*, &c. for the province of a metropolitan. See **PROVINCE**, and **METROPOLIS**.

Dioecesis, *διοικησις*, was originally a civil government, or prefecture, composed of divers provinces.

The first division of the empire into *dioecesis* is ordinarily ascribed to Constantine, who distributed the whole Roman state into four, viz. the *dioecesis* of Italy, the *dioecesis* of Illyria, that of the East, and that of Africa. And yet, long time before Constantine, Strabo, who wrote under Tiberius, takes notice, lib. xiii. p. 432, that the Romans had divided Asia into *dioecesis*, and complains of the confusion such a division occasioned in geography; Asia being no longer divided by people, but by *dioecesis*, each whereof had a tribunal, or court, where justice was administered. Constantine, then, was only the institutor of those large *dioecesis*, which comprehended several metropolises and governments; the former *dioecesis* only comprehending one jurisdiction, or district, or the country that had resort to one judge, as appears from this passage in Strabo, and, before Strabo, from Cicero himself, lib. iii. *Epist. ad Famil. Ep. 9.* and lib. xiii. *Ep. 67.* Thus, at first, a province included divers *dioecesis*, and afterwards a *dioecesis* came to comprise divers provinces. In after-times the Roman empire became divided into thirteen *dioecesis*, or prefectures; though, including Rome, and the sub-urbicary regions, there were fourteen. These fourteen *dioecesis* comprehended a hundred and twenty provinces; each province had a pro-consul, who resided in the capital, or metropolis; and each *dioecesis* of the empire had a consul, who resided in the principal city of the district.

On this civil constitution, the ecclesiastical one was afterwards regulated; each *dioecesis* had an ecclesiastical vicar, or primate, who judged finally of all the concerns of the church within his territory.

At present there is some farther alteration; for *dioecesis* does not now signify an assemblage of divers provinces, but is limited to a single province, under a metropolitan, or even to the single jurisdiction of a bishop.

England, with regard to its ecclesiastical state, is divided into two provinces, viz. *Canterbury* and *York*; the former province contains twenty-one *dioecesis*, and the latter three, besides the bishoprick of the Isle of Man, which was annexed to the province of York by Henry VIII. Every *dioecesis* is divided into archdeaconries, of which there are sixty in all; and each archdeaconry into rural deanries, and every deanry into parishes.

Gal. Brito affirms *dioecesis* to be properly the territory and extent of a baptismal, or parochial church; whence divers authors use the word to signify a simple parish.

DIOCLEIA, *Διοκλεια*, in *Antiquity*, a solemnity kept in the spring at Megara, in memory of the Athenian hero Diocles, who died in the defence of the youth he loved. Pott. *Archæol. Græc. lib. ii. cap. 20.*

DIOCELIAN Epocha. See **EPOCHÆ**.

DIOCTAMEDRIA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *δύο*, twice, *μέτρα*, eight, and *μέτρον*, a fold. The bodies of this genus are spars composed of twice eight palms, or two octagonal pyramids joined base to base, without any intermediate column. Hill's *Hist. of Foss. p. 211.*

DIODIA, in *Botany, the name of a genus of plants, of the *tetrandria monogynia* class; the characters of which are these: the perianthium consists of two leaves, of an oval figure, equal in size, and placed upon the germen; these remain when the flower is fallen. The flower is of the one-leaved labiated kind; its tube is slender and longer than the cup, its upper lip is erect and bifid, and the lower lip is expanded, and divided into two pointed segments. The stamina are four filaments of the thickness of a bristle; and two of these, which are opposite to one another, are fenset that flower than the others; the anthers are oblong, and versatile; the germen of the pistil is roundish, but in some degree four-cornered; this stands under the cup of the flower; the style is capillary, and of the length of the stamina, and the stigma is bifid; the fruit is a capsule, of an oval figure, with four corners, so as to appear square, and is incased with the cup grown larger; this is composed of two valves, and contains two cells; the seeds are double, of an oval oblong figure, and convex on one side, and plain on the other. There is one species.*

DIOECESIS, *διοικησις*, among the Romans, a prefecture of several provinces joined together, under the same governor, called *praefectus*. See **PREFECT** and **DIOCESS**.

DIOECIA, in *Botany, a class of plants which have the male and female plants, not in the same, but in different flowers, and those not on the same individual, but on different plants of the same species; either of which, though they are called the male and female plants, from their thus carrying the separate male and female flowers, might have arisen from the same feed. This class comprehends fourteen orders. See *Tab. of Botany*. The word is formed of the Greek *δύο*, twice, and *οικω*, habitation.*

Among the plants of this class are the willow, milletce, hemp, spinach, &c.

It is a curious observation, that there are no separate male and female plants in the classes of the apertiflorate or stellate plants, nor in the umbelliferous class, or that of the didynamia, tetradynamia, monadelphica, diadelphica, or syngenesia. The reason of which appears very evidently, from an observation of the conduct of the fructification in those classes. Linnaei *Gen. Plant. p. 470.*

DIOMEDIA, in *Ornithology*, a genus of *anseræ*, in the Linnæan system, with a straight bill, the upper mandible hooked at the end, and the lower truncated; including the albatross and Magellanic gannet.

DIOMEDIS Avis, in *Ornithology*, the name of a bird of the web-footed kind, with a slender beak, hooked at the end, and with its hinder toe not connected by the membrane that joins the rest. It is of the size of a common hen, but its neck and legs are much longer. Its colour is a dusky, and somewhat greyish brown, and under the belly there is more or less white; its beak is of a fine red, or in some of a yellowish colour, with a black end. It is found in the *Insula Diomedea*, now called *Tremiti*, in the Adriatic Sea, and is said to be peculiar to that place.

DIONE, in *Mythology*, a sea nymph, the daughter of Ocean and Thetis, and the mother of Venus by Jupiter.

DIONYSIA, or **DIONYSIACÆ**, solemn feasts, held among the ancients, in honour of Bacchus.

The word is formed from the Greek *Διονυσος*, of *Διώνη*, *Bacchus*; and that of *Διός*, the genitive of *Ζεύς*, *Jupiter*, and *Nysa*, a city in Egypt, on the frontiers of Arabia, where Bacchus is said to have been educated by the nymphs.

The *Dionysia* are the same with what are otherwise called *Orgia*, and by the Romans *BACCHANALIA* and *LIBERALIA*.

There

There were divers festivals under the denomination of *Διονυσια*, *Dionysia*; but the chief were two, viz. 1. The ancient, *αρχαία*, probably the same with *μεγάλα*, or the greater *Dionysia*, sometimes also called, by way of eminence, *Διονυσια*, without any other addition, as being the most celebrated of all Bacchus's festivals at Athens, where it was held in the month of Elaphebolion. 2. The new, *Νεώτερα*, probably the same with *μεγάλα*, or the lesser *Dionysia*, held in autumn, as a sort of preparation to the greater. Some will have this the same with *Διονυσια Λαυρα*, so called from *λαυρα*, a wine-press, and place it in the month Lenæon.

DIONYSIACA, in *Antiquity*, was a designation given to plays and all manner of sports acted on the stage; because play-houses were dedicated to Dionysus, i. e. Bacchus and Venus, as being the deities of sports and pleasure. Potter, *Archæol. Græc.* lib. i. cap. viii. tom. i. p. 41.

DIONYSIAN, or *Victorian Period*. See PERIOD.

DIONYSIAS Lapis, in *Natural History*, the name of a stone described by Pliny, and some other of the ancients, as a black stone, variegated with red spots. It is not now known what stone was intended by it. Plin. lib. xxxvii. cap. 10.

DIOPHANTINE Problems, in *Mathematics*, certain questions relating to square and cube numbers, and right-angled triangles, &c. the nature of which was determined by Diophantus, a mathematician of Alexandria, who is believed to have lived about the third century. We have his works, which were published with notes at Paris, in 1611, by Bachet de Meziriac; and another edition in 1670, with observations on every question, by M. Fermat.

In these questions it is endeavoured to find commensurable numbers to answer indeterminate problems; which bring out an infinite number of incommensurable quantities. For example, it is proposed to find a right-angled triangle, whose sides x, y, z , are expressed by commensurable numbers: it is known that $x^2 + y^2 = z^2$, z being the supposed hypotenuse. But it is possible to assume x and y so, that z will be incommensurable; for if $x=1$, and $y=2$, $z=\sqrt{5}$.

The art of resolving such problems consists in managing the unknown quantity or quantities in such a manner, that the square or higher power may vanish out of the equation, and then by means of the unknown quantity in its first dimension, the equation may be resolved without having recourse to incommensurables; e. g. let it be supposed to find x, y, z , the sides of a right-angled triangle, such as will give $x^2 + y^2 = z^2$. Suppose $x = x + u$, then $x^2 + y^2 = x^2 + 2xu + u^2$; out of which equation u^2 vanishes, and $x = \frac{y^2 - u^2}{2u}$; then assuming y

and u equal to any numbers at pleasure, the sides of the triangle will be $y, \frac{y^2 - u^2}{2u}$, and the hypotenuse $x + u$

$= \frac{y^2 + u^2}{2u}$; if $y=3$, and $u=1$, then $\frac{y^2 - u^2}{2u} = 4$, and

$x + u = 5$. It is evident that this problem admits of an infinite number of solution.

For the resolutions of such kind of problems, see SAUNDERSON'S *Algebra*, vol. ii. book 6.

DIOPTR, or *DIOPTRA*, in *Writers of Astronomy*, is frequently used for the hole, or index, pierced in the pinula, or sight of an alidade. See SICUTS.

DIOPTRA, among the *Ancients*, an instrument invented by Hipparchus, which served for several uses, as to level water, to take the height of towers, or places at a distance; to determine the places, magnitudes, and distances of the stars.

DIOPTRA, among *Surgeons*, denotes an instrument whereby to dilate the matrix, or anus, and inspect any ulcers therein; called also *speculum matricis* and *dilatatorium*.

DIOPTRICS, the doctrine of refracted vision, called also *anacathica*.

The word is originally Greek, formed of *διω*, *per*, *through*, and *τροπος*, *I go*.

Dioptrics is properly the third branch of optics, its office being to consider, and to explain the effects of light refracted by passing through different mediums, as air, water, glass, &c. and especially lenses.

The laws of *dioptrics* are delivered under the articles REFRACTION, LENS, &c. and the application thereof, in the construction of telescopes, microscopes, and other dioptrical instruments, under the articles TELESCOPE, and MICROSCOPE.

DIORTHOSIS, *διόρθωσις*, in *Surgery*, an operation, by which crooked or distorted members are made even, and restored to their primitive and regular shape.

DIOSCOREA, in *Botany*, a genus of the *dioscia* *herandria* class. Its characters are these; it hath male and female

Vol. II. N^o 98

flowers in different plants; the male flowers have a perianthium cut into six parts, and have no petals, but have six short hairy filamina; the female flowers have the same perianthium, have no petals, but have a three-crested germen. The perianthium becomes afterward a triangular capsule with three cells, opening with three valves, containing two compressed bordered seeds in each. There are five species, natives of warm climates; which will not thrive here, but in the bark stove. The *YAM*, or *yambei*, is one species of this plant. Linnaeus enumerates eight species.

DIOSCURIA, *Διόσκουρεια*, from *Διός*, *Jupiter*, and *κουρεια*, *infants*, in *Antiquity*, a festival in honour of the *Διόσκουρεια*, or Castor and Pollux, who were reputed to be the sons of Jupiter. It was observed by the Cypriotes, but more especially by the Spartans, whose country was honoured by the birth of these heroes. The solemnity was full of mirth, being a time wherein they shined plentifully of the gifts of Bacchus, and diverted themselves with sports, of which wrestling matches always made a part. Potter, *Archæol. Græc.* lib. ii. cap. 20. tom. i. p. 384.

DIOSMA, in *Botany*, *African Spinus*, a genus of the *pentandria monogynia* class. The characters are these: the flower hath a permanent empalement, which is divided into four acute segments, which are plain at the base; it hath five obtuse petals, which spread open, and are as long as the empalement; it hath five filamina, terminated by oval, erect summits, and a five-pointed hollow nectarium, sitting on the germen, from which arises a single style, crowned by an obsolete stigma; the germen afterward becomes a fruit composed of five compressed capsules, which open lengthways, each inclosing one smooth oblong seed. The several species of these plants grow naturally at the Cape of Good Hope.

DIOSPOROS, in *Botany*, a name given by some of the ancients to the lithospermum or grow-well. Some choose to write it *disphoros*, but this seems erroneous; the plain derivation of the word being from the Greek *Διός*, *Jupiter*, the seed of *Jupiter*. It seems to have obtained this name from its beauty and hardness. Pliny, lib. xxvi.

DIOSPYROS, in *Botany*, the name by which Linnaeus calls the guaiacana of Tournefort and others. See *Indian Date PLUM*.

DIOTA, among *Chemists*, a term used for a circulating or double vessel.

DIOXIA, *δίοξις*, in *Music*, a name sometimes given by the ancients to the *DIAPENTE*.

DIP of the *herman*. See DEPRESSION.

DIPHRI, a stone mentioned by the ancient writers; and said, by Pliny, to be of two kinds, the one black, the other white; and that these carried each of them the mark of one of the sexes, described by a line of the opposite colours; they were therefore called the male and female; the white was called the male, and had the character of the male sex figured in a black line; the other the female, and had the marks of that sex described by a white one. We know no such stones at this time.

DIPHRYGES, or *DIPHRYX*, in the *Ancient Pharmacy*, the scoria or calx of melted copper gathered in the furnace, when the metal was run out.

The word is formed from the Greek *δις*, *twice*, and *φρυξ*, *to roast*.

Dioscorides distinguishes three very different kinds of *diphryges*: one made of a kind of clay, or bole, dried in the sun; another made of marasite, or pyrites, burnt; and a third that is of the faces of copper.

The best *diphryges* is what tastes of copper, is acrid, astringent, and vehemently drying upon the tongue; qualities of which burnt ochre, though fold for *diphryges*, is destitute.

It is an astringent, a potent cleanser, absterive, and drier, represses excrescences of flesh, induces malignant and spreading ulcers to cicatrize; and mixed with turpentine or cerate, dissolves an abscess. Dioscorides, lib. v. cap. 120.

DIPHATHERA, *διπθερα*, among the *Ancients*, a garment made of skins, and worn only by shepherds and country-labourers.

DIPH THONG, *διπθυς*, in *Grammar*, a double vowel, or the union, or mixture, of two vowels pronounced together, so as only to make one syllable; as (1) the Latin *ae*, or *ai*, *ei*, or *oi*; (2) the Greek *ai*, *ei*; (3) the English *ai*, *au*, &c. See VOWEL, and SYLLABLE. The word is Greek, and is compounded of *δις*, *twice*, and *θυς*, *found*.

As answers to *ai*, the proper; and *ae*, the improper diphthong of the Greeks; e. g. *Αἰνέσις*, *Αἰναι*; *σφαῖρα*, &c. And, on the contrary, the Romans, when they had occasion to divide their *ai*, changed it into the Greek, *ai*; e. g. *αιναι*, for *αιναι*, &c.

ai, by some is made a Latin diphthong, as in *ai*, *Caius*, &c. But in *ai*, and *ai*, *i* manifestly belongs to the

the latter syllable; and the Greeks write not $\gamma\alpha\iota$ $\sigma\iota$, but $\gamma\alpha\iota\sigma\iota$; whence it seems plain that $\sigma\iota$, in the Latin tongue, is not a diphthong as in the Greek.

The Latins pronounced the two vowels in their diphthongs much as we do, with this exception, that the two were not heard equally, but the one was somewhat weaker than the other; though the division was made with all the delicacy imaginable; among us most of the Latin diphthongs are lost in the pronunciation; their ae and oe are only spoken as e i , so also the English ea , eo , &c. though written with two characters, are pronounced as simple sounds.

In English, French, and divers other languages, one may distinguish diphthongs with regard to the eye, from diphthongs with regard to the ear.

A diphthong with regard to the eye, is formed of two vowels, meeting in the same syllable, whether the particular sound of each of them be heard in the pronunciation, or whether the sound of one of them be drowned; or, lastly, whether a new sound, different from either of them, result from both. In the two latter cases, it is with some impropriety that we call them diphthongs: the first, only, are real diphthongs, as being such both to the eye and ear.

Diphthongs, with regard to the ear, are either formed of two vowels, meeting in the same syllable, whose sounds are severally heard; or of three vowels in the same syllable, which only afford two sounds in the pronunciation.

On this last occasion, diphthongs, with regard to the ear, are triphthongs with regard to the eye.

English diphthongs, with regard both to the eye and ear, call proper diphthongs, are ai , as in *fair*; au , in *loud*; ee , in *seed*; eo , in *void*; eo , in *food*; and ou , in *house*.

English improper diphthongs, or diphthongs with regard to the eye, are ao , pronounced only like a , as in *Arden*; ea , like a , as in *swear*, *heart*; or like e , as *already*; or like er , as *wear*; eo , like e , in *essence*; or like e , as in *George*; eu , or eo , like u , as *Deuteronomy*; ie , like i , as *chiefs*; oi , like o , in *sovereign*; or like o , in *deceit*; ou , as in *elbow*, *doat*; or, as in *doe*, *economy*; ur , as in *guess*; and ui , as in *guilt*, *revert*.

DIPHYSES, from $\delta\iota\phi\upsilon\sigma\iota\varsigma$, and $\gamma\epsilon\gamma\epsilon\mu\epsilon\iota$, in *Natural History*, a name given by some authors to a kind of stone, which represents both the male and female parts of generation of the human species; and owes its figures merely to the accidental conformation of the hinge and protuberances of a shell, in which it has been formed.

We have a species of chama, whose external form at the mouth represents the female pudenda; but the figure of this stone is owing to the internal shape of the shell in which it has been cast. This is an unknown species of concha anomia, which has such ridges in one shell, and such cavities in the other, that the stone call or moulded in it, has on one side the figure of the female pudenda, and on the other the male; it is usually of a dusky brown colour, and of a ferruginous substance. As the same shell may, however, have received in different places different substances into its cavity, all which would necessarily be of this form, we hear, among authors, of some black, and some white stones of this kind. Authors have treated of this stone in a very idle and fabulous manner; but this is its true history.

DIPLASIASMUS, from $\delta\iota\pi\lambda\alpha\sigma\iota\alpha\sigma\mu\circ\varsigma$, of $\delta\iota\pi\lambda\alpha\sigma\iota\alpha\varsigma$, double, in *Mechanics*, a reduplication of discales.

DIPLASIASMUS is also used for two muscles in the arm, which serve to turn it about.

DIPLOE, from $\delta\iota\pi\lambda\omega\varsigma$, double, in *Anatomy*, a spongy, medullary substance, separating the two tables of the cranium, and together with them constituting the skull.

The substance of the diploe being spongy, easily imbibes the blood; and is found separated into an infinite number of little cells, of different magnitudes, which receive little branches of arteries from the brain, and give passage to the little veins that proceed to the sinuses of the dura mater.

DIPLOIS, from $\delta\iota\pi\lambda\omega\iota\varsigma$, in *Antiquity*, a double pallium, or cloak worn chiefly by the Cynics.

DIPLOMA, from $\delta\iota\pi\lambda\omega\varsigma$, double, an instrument given by some colleges and societies, on taking a degree, on passing examination, as a proof or qualification for any advancement to title, or pre-eminence, or introduction to the exercise of a profession.

DIPLOMA, in *Chemistry*, denotes a double vessel. Thus when one vessel is put into another, the ingredients in the first, and the fire under the last, the chemists call it boiling in diploma.

DIPONDUS, in the *Scripture Language*, is used by St. Luke, to signify a certain coin, which was of very little value. Our translation of the passage is, *Are not two sparrows sold for two farthings?* In St. Matthew, who relates the same thing, we read, *Are not two sparrows sold*

for a farthing? The Greek reads *asferion* instead of *as*. Now *asferion*, as some say, was worth half an *as*, that is to say, four French deniers and $\frac{1}{2}$; and, according to others, two deniers and $\frac{1}{2}$. *Dipondus* seems rather to signify half an *as*. Calaneo Dictio. Bibl. Luke xii. 6. Matt. x. 29.

Dr. Arbuthnot differs in opinion from the author last quoted. He says, that this coin was at first *libellus*, or a pound weight; and even when diminished, it retained the name of *libella*. So that *dipondus* denotes two *as*.

DIPPING, in *Minerology*, a term used to express the deviation of the veins of ore, from that regular and straight line in which they usually run. A great deal of the skill of the miners consists in the understanding of this dipping of the veins, and knowing how to manage it. In Cornwall they have this general rule to guide them in this respect: most of their tin-lodes, which run from east to west, constantly dip toward the north. Sometimes they underlie; that is, they slope down towards the north three foot in eight, perpendicular. This must carefully be observed by the miners, that they may exactly know where to make their air-shafts when occasion requires; yet, in the higher mountains of Dartmoor, there are some considerable lodes which run north and south; these always underlie toward the east.

Four or five lodes may run nearly parallel to each other in the same hill; and yet, which is rare, they may meet all together in one hatch, as it were a knot, which well tins the place, and so separate again, and keep their former distances. Phil. Trans. N^o 69.

DIPPING-Needle, or Inclining Needle, a magnetical needle, so hung, as that, instead of playing horizontally, and pointing out north and south, one end dips, or inclines to the horizon, and the other points to a certain degree of elevation above it.

Or a dipping-needle may be defined, with Mr. Whiston, to be a long straight piece of steel, represented *Tab. Navigationis*, fig. 7. every way equally poised on its centre, and afterwards touched with a load-stone; but so contrived, as not to play on the point of a pin, as does the common horizontal-needle, but to swing in a vertical plane, about an axis parallel to the horizon; and this in order to discover the exact tendency of the power of magnetism.

Mr. Nairne, an ingenious instrument-maker in London, made a dipping-needle in 1772 for the board of longitude, which was used in the voyage towards the north-pole. This is represented *Tab. Navigationis*, fig. 8. The needle AA is twelve inches long, and its axis, the ends BB of which are made of gold, alloyed with copper, rests on friction wheels CCCC, of four inches diameter, each end on two friction wheels; which wheels are balanced with great care. The ends of the axes of the friction wheels, are likewise of gold alloyed with copper, and moved in small holes made in bell-metal; and opposite to the ends of the axes of the needle, and the friction wheels, are flat agates, set in at DDD, finely polished. The magnetic needle vibrates within a circle of bell-metal, EEE, divided into degrees and half degrees; and a line, passing through the middle of the needle to the ends, points to the divisions. The needle of this instrument was balanced before it was made magnetical; but by means of a cross, the ends of which are FFFF (contrived by the reverend Mr. Mitchell), fixed on the axis of the needle, on the arms of which are cut very fine screws to receive small buttons, that may be screwed nearer or farther from the axis, the needle may be adjusted both ways to a great nicety, after being made magnetical, by reversing the poles, and changing the sides of the needle. GG are two levels, by which the line of 0 degrees of the instrument is set horizontal; by means of the four adjusting screws LLLL; H is the perpendicular axis, by which the instrument may be turned, that the divided face of the circle may front the east or west; to this axis is fixed an index I, which points to an opposite line on the horizontal plate K, when the instrument is turned half round; MMMM are screws which hold the glass cover to keep the needle from being disturbed by the wind. When this needle is constructed for sea, it is supported by a universal joint on a triangular stand, and adjusted vertically by a plumb-line and button above the divided circle and the dove-tail work at the upper 90; and the divisions on the circle are adjusted so as to be perpendicular to the horizon by the same plumb-line, and an adjoining screw; and when it is adjusted, a pointer annexed to a screw, which serves to move the divided circle, is fixed at the lowest 90. Whenever the instrument is used to find the dip, it must be so placed that the needle may vibrate exactly in the magnetic meridian. Phil. Trans. vol. lxi. art. 35. Phipps's Voyage, &c. Appendix, p. 119. See also the description of

of a new *dipping-needle*, by Mr. Lorimer of Pensacola, in the Phil. Trans. vol. lxx. part i. p. 82.

The inventor of the *dipping-needle*, Mr. Whiston observes, was, without all question, an Englishman, Robert Norman by name, a compass-maker at Wapping, about the year 1576; this is not only testified by his own account, in his New Attractive, but was allowed by Dr. Gilbert, and other writers of that time. The occasion of the discovery he himself relates, viz. that it being his custom to finish, and hang the needles of his compasses, before he touched them, he always found that, immediately after the touch, the north-point would bend, or decline downward, under the horizon; inasmuch that, to balance the needle again, he was always forced to put a piece of wax on the south-end, as a counter-poise.

The constancy of this effect led him, at length, to observe the precise quantity of the *dip*, or to measure the greatest angle which the needle would make with the horizon.

This, in the year 1576, he found at London to be $71^{\circ} 50'$. It is not absolutely certain whether the *dip* varies, as well as the horizontal direction, in the same place. Mr. Graham made a great number of experiments with the *dipping-needle* in 1723, and found the *dip* to be between 74° and 75° degrees. Mr. Nairne, in 1772, found it to be somewhat above 72° . The trifling difference between the first observations of Mr. Norman, and the last of Mr. Nairne, would lead us to imagine that the *dip* was unalterable; but Mr. Graham, who was a very accurate observer, makes the difference more considerable. Phil. Trans. abr. vol. vii. p. 280, and Phil. Trans. vol. lxxi. art. 35.

It is certain, however, from a great number of experiments and observations, that the *dip* is variable in different latitudes, and that it increases in going northward. It appears from a table of observations made with the marine *dipping-needle*, already described, in a voyage towards the north-pole, in 1773, that in lat $60^{\circ} 18'$, the *dip* was 75° ; in lat. $70^{\circ} 45'$, it was $77^{\circ} 52'$; in lat. $80^{\circ} 12'$, it was $81^{\circ} 52'$; and in lat. $80^{\circ} 27'$, $82^{\circ} 23'$. Phipps's Voyage, &c. p. 122. See also the observations of Mr. Hutchins, made in Hudson's Bay and Straits. Phil. Trans. vol. lxx. part i. art. 14.

Burrows, Gilbert, Ridley, Bond, &c. endeavoured to apply this discovery of the *dip* to the finding of the latitude; and the last author, going farther, likewise proposed the finding of the longitude thereby; but for want of observations and experiments, he could go no length. Mr. Whiston, being furnished with the farther observations of colonel Windham, Dr. Halley, Mr. Pound, Mr. Cunningham, Pere Noel, Pere Feuille, and his own, has improved very much on the doctrine and use of the *dipping-needle*; brought it to more certain rules; and endeavoured, in good earnest, to find the longitude thereby. In order to this, he observes, 1st, That the true tendency of the north or south end of every magnetic needle, is not to that point of the horizon, to which the horizontal needle points, but towards another, directly under it, in the same vertical, and in different degrees under it, in different ages, and at different places.

2dly, That the power by which an horizontal needle is governed, and all our navigation ordinarily directed, is proved to be but one quarter of the power by which the *dipping-needle* is moved; which should render the latter far the more effectual and accurate instrument.

3dly, That a *dipping-needle*, a foot long, will plainly shew an alteration of the angle of inclination, in these parts of the world, in half a quarter of a degree, or $7\frac{1}{2}$ geographical miles; i. e. supposing that distance taken along, or near a meridian; and a needle of four feet, in two or three miles.

4thly, A *dipping-needle*, four feet long, in these parts of the world, will shew an equal alteration along a parallel; as one of a foot long will shew along a meridian; i. e. this will, with equal exactness, shew the longitude, as that the latitude.

This depends on the position of the lines of equal *dip*, in these parts of the world, which are found to lie about fourteen or fifteen degrees from the parallels.

Hence he argues, that as we can have needles of five, six, seven, eight, or more feet long, which will move with strength sufficient for exact observation; and since microscopes may be applied to the viewing the smallest divisions of degrees on the limb of the instrument, it is evident, the longitude at land may be found thereby to less than four miles.

And as there have been many observations made at sea, with the same instrument, by Noel, Peuille, &c. which have determined the *dip*, usually within a degree, sometimes within 1° or $\frac{1}{2}$ of a degree, and this with small needles, of five or six, or at the most nine inches long; it is evident, the longitude may be found, even at sea,

to less than half a quarter of a degree. Thus much premises the observation itself follows.

To find the longitude, or latitude, by the *DIPPING-needle*. If the lines of equal *dip*, below the horizon, be drawn on maps, or sea-charts, from good observations; it will be easy, from the longitude known, to find the latitude; and from the latitude known, to find the longitude, either at sea or land.

Suppose, e. gr. you were travelling, or sailing along the meridian of London, and found the angle of *dip*, with a needle of one foot, to be 75° , the chart will shew, that this meridian, and the line of *dip*, meet, in the latitude of $53^{\circ} 11'$; which, therefore, is the latitude sought. See LATITUDE.

Or, suppose you were travelling, or sailing along the parallel of London, i. e. in $51^{\circ} 32'$ north latitude, and you find the angle of *dip* to be 74° . This parallel, and the line of this *dip*, will meet in the map in $1^{\circ} 46'$ of east longitude, from London; which is, therefore, the longitude sought.

DIPSACUS, in Botany. See TRACHEE.

DIPSACUS, in Medicine, according to some, is the same with a DIABETES.

DIPSAS, a sort of serpent, the biting whereof produces such a thirst as proves mortal; whence it is called *dipsas*, which in Greek signifies *thirsty*. In Latin it is called *serpens*, a *serpent*. Moles speaks of it in Deut. viii. 15.

The Hebrew word *tsalmun* answers very well to the Greek *dipsas*, and expresses the thirst occasioned by the biting of this serpent. Some by the Hebrew *tsalmun* understand a desert or dry place.

DIPTERA, from *dis*, and *pteron*, wing, in Zoology, an order of insects, which have only two wings, and under each wing a style or oblong body, terminated by a protuberance or head, and called a balancer.

DIPTERE, or DIPTERON, in the Ancient Architecture, a temple surrounded with a double row of columns, which form a sort of porticos, called wings, or ifles.

The word is Greek, formed from *dis*, twice; and *pteron*, ala, wing.

DIPTOTES, from *dis*, and *ptotes*, of *ptotes*, cede, in Grammar, a kind of irregular nouns, having only two cases; as *forti*, *fortis*.

DIPTYCHA, in Antiquity, a public register, wherein were written the names of the consuls, and other magistrates, among the heathens; and of bishops, and deacons as well as surviving brethren, among the Christians.

The word *diptycha* is formed from the Greek *dipteron*, or *dipteron*, and that from *diptero*, a masculine noun derived from *ptero*, I fold, or plait. From its future *ptero* is formed *pteron*, a fold, or plait; to which adding *dis*, twice, we have *dipteron*, in the genitive *dipteron*, whence the nominative neuter, *dipteron*, q. d. a book folded in two leaves; though there were some in three, and others in four or five leaves. An ingenious author imagines this name to have been first given them to distinguish them from the books that were rolled, called *rotunda*. See VOLUME and BOOK.

It is certain there were profane *diptycha* in the Greek empire, as well as sacred ones in the Greek church. The former were the matricula, or register, wherein the names of the magistrates were entered; in which sense *diptycha* is a term in the Greek chancery.

DIPTYCHA, sacred. The word is plural; *diptycha* being a double catalogue, in one whereof were written the names of the living, and in the other those of the dead, which were to be rehearsed during the office. We meet with something not unlike the sacred *diptycha* of the Greeks, in the canon of the mass, according to the Latin usage; where the people are enjoined to pray once for the living, and once for the dead; several saints are invoked in different times, &c.

In these *diptycha* were entered the names of bishops, who had governed their flocks aright; and these were never expunged out of the same, unless they were convicted of heresy, or some other gross crime. In the *diptycha* were likewise entered the names of such as had done any signal service to the church, whether they were living or dead, and mention was made of them in the celebration of the liturgy.

Cassaubon, in his observations on Athenensis, lib. vi. cap. 14. supposes the Christians to have borrowed the custom of writing names in a book, and rehearsing them at mass, from the heathens, who entered the names of persons they would do any signal honour to, in the vestra of the Salii; as was done to Germanicus and Verus, sons of the emperor Marcus Aurelius, and long time before, during the age of the republic, to Mamurcus Veturius, and Lucius Volumnius, as we are told by Tacitus, lib. ii. Spartian, Ovid, Festus, Plutarch, &c. But Fa. Rofweyde does not approve this notion of Cassaubon. The pretended St. Dionysius, a very ancient author,

author, says the contrary, and asserts the first establishment of this usage to have been founded on scripture, 2 Tim. ii. 19. Palm xvi. 15. Rowley adds Ecclesiastic. xlv. 1. and takes these to have been the passages the ancient church had a view to, rather than the Salian verses.

The *profane diptycha* were frequently sent as presents to princes, &c. on which occasion they were finely gilt, and embellished; as appears from Symmachus, lib. ii. ep. 81. Those presented were usually of ivory. The first law, De Expend. Ludor. C. Theod. forbids all magistrates below consuls to make presents of *diptycha* of ivory in the public ceremonies.

DIAPYRENON, from *δία* and *πυρρον*, a berry, in Surgery, the name of a probe, with a double bottom at the end, resembling two small berries growing together.

DIRAE, in Mythology. See **FURIES**.

DIRCA, in Botany a genus of the *Standria monogynia* class. Its characters are these: the flower is tubulose, and has no empanment: it has eight stamina, which are longer than the tube; the flower is succeeded by a berry with one cell, including a single seed. There is but one sort of this genus, called by the French *buis de plomb*, *houlewood*; and by the English in America leather-wood, from its lightness. It is a low shrub in this country, seldom rising above four or five feet high; and is very nearly allied to the mezereon.

DIRECT, in Arithmetic. The *Rule of Three DIRECT* is that opposite to the inverse. See *RULE of proportion*.

DIRECT, in Astronomy. We consider the planets in three states; viz. *direct*, *stationary*, and *retrograde*. See **PLANET**.

They are said to be *direct*, when they appear to move forward, according to the succession of the signs; and *retrograde*, when they go the contrary way.

DIRECT, in Matters of Genealogy, is understood of the principal line, or the line of ascendents and descendents; in contradistinction to the collateral lines.

Thus the house of Bourbon is said to descend in a *direct* line from St. Louis. The heirs in a *direct* line always precede those in the collateral line.

A very good historian uses the phrase *DIRECT speech*, or *harangue*, when he introduces any one speaking, or haranguing of himself: when the historian speaks, and only rehearses the chief points of what was delivered by the speaker, it is called an *indirect speech*.

DIRECT $\left\{ \begin{array}{l} \text{Erect} \\ \text{East} \\ \text{West} \end{array} \right\}$ *dials*, are those whole planes lie directly open to the east, or west points of the heavens, or parallel to the meridian of the place. See **DIAL**.

DIRECT south, or north $\left\{ \begin{array}{l} Inclining \\ Reclining \end{array} \right\}$ *dials*. See **DIAL**.

DIRECT, in Music, is a mark set at the end of a staff, especially at the foot of a page upon that line or space where the first note of the next staff is set.

DIRECT, in Optics. *Direct vision* is that performed by *direct rays*; in contradistinction to vision by refracted, or reflected rays.

Direct vision is the subject of optics, which prescribes the laws and rules thereof. See **VISION**.

DIRECT rays are those which pass in right lines from the luminary to the eye, without being turned out of their rectilinear direction by any intermediate body, either opaque or pellucid. See **RAY**.

DIRECT sphere. See **RIGHT sphere**.

DIRECTION, in Astronomy, the motion, and other phenomena, of a planet, when *direct*. See **PLANET**.

DIRECTION, in Astrology, is a kind of calculus, whereby they pretend to find the time wherein any notable accident shall befall the person whose horoscope is drawn.

For instance, having established the sun, moon, or ascendant, as matters, or significators of life; and Mars, or Saturn, as promisers, or portenders, of death; the *direction* is a calculation of the time wherein the significator shall meet the portender.

The significator they likewise call *apheta*, or giver of life; and the promiser, *aureta*, *promissor*, or giver of death.

They work the *directions* of all the principal points of the heavens, and stars, as the ascendant, mid-heaven, sun, moon, and part of fortune. The like is done for the planets, and fixed stars; but all differently, according to the different authors.

DIRECTION, *line of*, in Gunnery, was formerly marked on guns with a slit or cavity at the breech, and a button at the muzzle, so that they were directed in the same manner as sailing-pieces are; but as the platforms on which the cart carriages rest are never laid so exactly level, but that one wheel is always higher than another, this line of *direction* must be false, and has, therefore, in modern practice, been laid aside; and the centre-line of a piece is found every time it is fired, by a plummet, or instrument, which Mr. Muller complains of as a tedious

and uncertain method; and he recommends returning the line of *direction*, as more expeditious, and more certain than the common practice. System of Math. vol. v. p. 90, and 230.

DIRECTION, or Line of DIRECTION, in Mechanics, is particularly used for a line passing from the centre of the earth through the centre of gravity of a body, and the support or fulcrum that bears it.

A man must necessarily fall down as soon as the centre of his gravity is out of the line of *direction*.

DIRECTION, line of, in Mechanics, also denotes that wherein a body moves, or endeavours to proceed.

DIRECTION, angle of, in Mechanics, is that comprehended between the lines of *direction* of two conspiring powers.

DIRECTION, quantity of, in Mechanics, is used for the product of the velocity of the common centre of gravity in a system of bodies, by the sum of their masses.

In the collision of bodies, the quantity of *direction* is the same before, and after the impulse. Bernoulli, Discours sur le Mouvement. Oper. tom. iii. p. 32, and 36.

DIRECTION chamber, in Chemistry. See **CHAMBER**.

DIRECTION of the loadstone, that property whereby the magnet, or a needle touched by it, always presents one of its ends towards one of the poles of the world, and the opposite end to the other pole.

The attractive property of the magnet was known long before its *directive*; and the *directive* long before the inclinatory.

DIRECTION, magnetical, is also used in the general for the tendency, or turning of our earth, and all magnetical bodies, to certain points.

The *direction* of a loadstone denotes its **POLARITY**.

The situation of the earth, we know, is such, that its axis is in the axis of the universe; and therefore its poles, and cardinal points, exactly correspond to those thereof. This situation some account for hence, that it is the most commodious with regard to the aspects and influences of the heavenly bodies, and renders it the fittest habitation for man. Others hold this position of the earth an effect of a magnetic virtue; and suppose a celestial pole, endued with a like magnetic virtue; which, extending as far as our earth, draws the correspondent part thereof, the pole, towards itself.

DIRECTION, number of, in Chronology. See **NUMBER**.

DIRECTLY. In Geometry, we say, two lines lie *directly* against each other, when they are parts of the same right line.

In Mechanics, a body is said to strike, or impinge *directly* against another, if it strike in a right line perpendicular to the point of contact.

A sphere, particularly, strikes *directly* against another when the line of *direction* passes through both their centres. See **PERCUSSION**.

DIRECTOR, in Commercial Policy, a person who has the management of the affairs of a trading company; thus we say, the *directors* of the India COMPANY, South-sea COMPANY, &c. See **BANK**.

DIRECTORS of Creditors, in the Commercial Policy of France, are persons of ability and property, chosen by votes of the creditors, to inspect and examine the debtor's affairs, and to procure as far as possible by common methods of justice, the payment of each person's debt. See **ASSIGNEES**.

DIRECTORS-general of the five great farms of the GABLS and AIDE, &c. in France, are chief commissioners, who have the direction of these farms, each in the districts appointed by the general farmers.

DIRECTOR, in Surgery, a grooved probe, to direct the edge of the knife or scissars in opening sinuses or fistulas, that, by this means, the subjacent vessels, nerves, and tendons, may remain unharmed. Sometimes one end is made in form of a spoon, to contain powders to sprinkle upon wounds or ulcers. Sometimes also it is forked at the end to divide the frænum of the tongue. See *Tab. III. Surgery*, fig. 33. Heister's Surg. Introduct. sect. 36.

DIRECTOR penis, in Anatomy, a muscle of the penis, called more usually **ERECTOR**. See *Tab. Anat. (Splanchn.)* fig. 15. *lit. ee*.

DIRECTORY of public worship, was drawn up by the assembly of divines at Westminster, pursuant to an ordinance which passed the house of lords in 1644, repealing the statutes of Edward VI. and of Elizabeth, for uniformity in the common prayer. This *directory* set aside the use of the Liturgy, and allowed of no church-music besides that of singing the psalms.

DIRECTRIX, in Geometry. See **DIRECTRIX**.

DIRECTRIX of the parabola. See **CONIC SECTIONS**.

DIRIBITORES, among the Romans, officers appointed to distribute tablets to the people at the COMITIA.

DIRIGENT, a term in Geometry, expressing the line of motion, along which a deficient line, or surface, is carried in the genesis of any plane, or solid figure.

Thus,

Thus, if the line AB (*Tab. II. Geometry, fig. 33*) move parallel to itself, and along the line AC, so that the point A always keeps in the line AC, a parallelogram, as ABCD, will be formed, of which the side AB is the descender, and the line AC the *discent*. So also, if the surface ABCD be supposed to be carried along the line CE, in a position always parallel to itself in its first situation, the solid ADEH will be formed, where the surface AD is the descender, and the line CE is the *discent*.

DIRITTA, in the *Italian Music*, a term intimating that the piece is to be played or sung in conjunct degrees. Thus, *contrapunto alla diritta*, according to Angelo Bernardi, is when one is obliged to *raise* or *fall* the voice by the same degrees, i. e. by an equal number ascending or descending, without making a leap, even of the interval of a third. Brofs. Dict. Mus. in voc.

DIS, an inseparable particle prefixed to divers words; the effect whereof is, either to give them a signification contrary to what the simple words had: as in *disfract*, *disfractis*, *disperior*, &c. or to intimate a separation, detachment, distribution, &c. as in *disjunct*, *disjunctis*, *disfractis*, *disperior*, &c.

DISABILITY, in *Law*, is when a man is made incapable to inherit lands, or take any benefit, which otherwise he might do; which may happen four ways; viz. by the act of the ancestor; by the act of the party; by the act of law; and by the act of God.

DISABILITY by the act of the ancestor, is where a man is stinted of treason, or felony; by which attainder his blood is corrupted, and thereby himself and his children are *disabled* to inherit.

DISABILITY by the act of the party himself, is where a man binds himself by obligation, that, upon a surrender of a lease, he will grant a new estate to the lessee; and afterwards he grants the reversion to another, which puts it out of his power to perform it.

DISABILITY by the act of the law, is when a man, by the sole act of law, without any thing by him done, is rendered incapable of the benefit of the law: as, an alien born; so that if a man born out of the king's allegiance, will sue an action, the tenant, or defendant, may say, he was born in such a country out of the king's allegiance, and demand judgment, if he shall be answered; for the law is our birth-right, to which an alien is a stranger, and therefore *disabled* from taking any benefit thereby.

DISABILITY by the act of God, is when the party is *non compos mentis*, or *non sane memoria*, which *disables* him, that in all cases, where he gives, or passes any thing, or estate from him, after his death it may be annulled, and voided.

There are also other *disabilities* by the common law, as of idioy, infancy, and coverture, for making of grants, &c. and by statute, as papists are *disabled* for making any presentation to a church, &c. and officers not taking the oaths for holding offices.

DISABLED, in *Sea Language*, is applied to a ship, when by the loss of her masts, yards, or rigging, or other damage, she is rendered incapable of prosecuting her voyage, without great difficulty and danger.

DISAFFORESTED. See **DEAFFORESTED**.

DISARM, in the *Manège*. To *disarm* the lips of a horse, is to keep them subject, and out from above the bars, when they are so large as to cover them, and prevent the true pressure or appui of the mouth, by bearing up the bit, and so rendering the horse to feel the effects of it upon the bars.

DISARMING, the act of depriving a person of the use or possession of arms. See **ARMS**.

On the conclusion of a peace, it is usual for both sides to *disarm*. We have divers laws for *disarming* papists, and all recusants. Under king George I. a law was made for *disarming* the Highlanders; none of whom, except peers, or gentlemen of 400*l.* per ann. are to wear any arms in the field, on the road, or at market. 1 Geo. I. stat. 2. cap. 34.

The game law has, in effect, *disarmed* all the common people of England, having under 100*l.* a year in landed estate, except the servants of lords of manors. Yet, by the ancient policy of England, the whole nation was obliged to bear arms.

DISBOSSATION, *Disboscat*, is turning wood-ground into arable or pasture, an *affaring*. See **ASSART**.

DISBURDENING of trees, in *Gardening*, the taking off leaves and fruits when too numerous, that those left may grow the larger.

DISC, or **DISK**, *Discus*, in *Antiquity*, a kind of round quoit, or a piece of stone, or metal, about a foot over, used by the ancients in their exercises.

The *discus* of the ancients was flat and round, resembling the apparent figure of the sun.

Vol. II. N^o. 98.

The exercise of the *discus* was one of those practised in the solemnities of their public games: it consisted in pitching, or throwing a *discus* either upward, or straight forward; and he who threw it highest, or farthest, bore away the prize.

Those who practised in this game were called *discoboli*, i. e. *throwers of the discus*.

The poets tell us, that Hyacinth, a favourite of Apollo, playing at the *discus* with that god, was killed by a blow of Apollo's *discus*, which his rival Zephyrus diverted from its course, and cast on the boy's head.

The *discus* was thrown by means of a little cord made of hair, as appears from Claudius, lib. ii. in Eutrop. eum. 22. ver. 359, & seq. Ovid describes this sport, Metam. lib. 2. ver. 175. The Romans learnt the game of the *discus* of the Greeks, and practised it among themselves. Dempster, Paraleip. in Rebus. Antiq. Rom. lib. v. cap. 1. and Pet. Faber, Agonisticon, lib. ii. cap. 1. treat of the direction of the *discus*.

DISC, or **DISK**, in *Astronomy, the body or face of the sun, or moon; such as it appears to us. For, though they are really spherical bodies, they are apparently circular planes.*

The *disc* is conceived to be divided into twelve equal parts, called *digits*; by means whereof it is, that the magnitude of an eclipse is measured, or estimated. Such an eclipse was so many digits, or parts of the sun, or moon's *disc*.

In a total eclipse of either of those luminaries, the whole *disc* is obscured, or darkened in a partial eclipse only part of them. See **ECLIPSE**.

DISC, *illuminated*, of the earth. See **CIRCLE**, of *illumination*.

DISC, *Discus*, in *Botany*, is applied to the central, or middle part of radiated flowers; as being round, and plain like a quoit.

This is sometimes also called the *pelvis*, or *basin*. The *disc* is composed of several *discus* perpendicularly placed.

DISC, in *Optics*, the magnitude of a telescope glass; or the width of its aperture, whatever its figure be, whether a plain, convex, meniscus, or the like.

DISC, in the Greek Liturgy, is nearly the same thing with the *patena* in the Latin. See **PATENA**.

In the Greek church the consecrated bread is laid on a *discus*, as in the Latin church it is on a *patena*. The *discus* only differs from the *patena*, in that it is bigger and deeper, as resembling a plate, which was the proper signification of the word *discus* among the ancients.

DISCEIT, in our *Old Writers*. See **DECEIT** and **DECEPTION**.

DISCENT. See **DESCENT**.

DISCERNING, an act of the mind, whereby it distinguishes between ideas.

On this faculty of *discerning* depends the evidence and certainty of several, even general propositions, which pass for innate truths; and which in reality flow from this clear *discerning* faculty of the mind, whereby it perceives two ideas to be the same, or to be different.

In being able nicely to distinguish one thing from another, where there is the least difference, consists in great measure that exactness of judgment, and clearness of reason, which is to be observed in one man above another; which is quite opposite to wit: this consists most in the assemblage of ideas, and putting those together with quickness and variety, which have the least resemblance to form agreeable visions; whereas judgment separates carefully those ideas, wherein can be found the least difference, to prevent error and delusion. To the well distinguishing of our ideas, it chiefly contributes, that they be clear and determinate; and when they are so, there will not arise any confusion, or mistake, about them, though the senses should convey them from the same object differently on different occasions. See **JUDGMENT**.

DISCEUS, or **DISCIFORMIS Canalis**. See **DISCUS**.

DISCHARGE, in *Electricity*. See **CHARGE**.

DISCHARGE, in *Law*. See **CHARGE**, in *Law*.

DISCHARGE, in *Military Language*, is the dismissal of a soldier from the troop or company to which he belonged, either by his own request, or when after long and faithful service, he is entitled to his majesty's bounty.

To **DISCHARGE**, in *Sea Language*, signifies to unload a ship, or take out her stores, ammunition, artillery, &c. When applied to the crew, it implies to dismiss them from immediate service.

DISCHARGER, or **DISCHARGING Rod**, in *Electricity*, consists of a handle of glass or baked wood. A *Thin-Electricity*, fig. 33, and two bent metal rods B, terminating in points, and capable of being raised into the knob D, which move by a joint C, fixed to the handle A. Thus it may be used either with the points or balls, as occasion requires; and by being made moveable

on a joint, it may be applied to larger or smaller jars at pleasure. By bringing one of these knobs or points to one coated side of a charged electric, and the other to the other side, or to any conductor connected with it, the communication is completed between the two sides, and the electric is discharged.

DISCHARGER, the *universal*, contrived by Mr. Hendy, consists of a flat board A (Tab. II. Electricity, fig. 14) sixteen inches long, four broad, and about one inch thick, and two glass pillars B, B, cemented in two holes upon the board A, and furnished at their tops with brass caps; each of which has a turning joint, and supports a spring tube, through which the wire DC slides. Each of these caps is composed of three pieces of brass, connected in such a manner that the wire DC not only slides through the socket, but may be moved both vertically and horizontally. Each of the wires DC, DC is furnished with an open ring at one end, and at the other end with a brass ball D, which, by a short spring socket, may be slipped on to either extremity, or removed from it at pleasure. E represents a strong circular piece of wood, five inches in diameter, in the surface of which a slip of ivory is inlaid; it rests on a cylindrical foot, sitting the cavity of the socket F, which is fastened in the middle of the board A, and by means of a screw G, the circular board may be fixed at any required height. To this instrument belongs a small press H, composed of two oblong pieces of board, which may be pressed against each other by two screws A, A; the lower of these boards has a cylindrical foot of the same size with that of the circular board E, and thus the press may be fixed in the socket F, in the room of E. Cavallo's Electr. p. 164, &c.

This instrument may be used in a variety of electrical experiments. Thus, glass may be lined with metals, by putting a small slip of gold, silver, or brass-leaf, between two slips of common window-glass, about three inches long, and half an inch wide, and pressing them between the boards of the press H; then, if a flock be made to pass through this metallic leaf, a small part of which projects beyond the slips of glass at each end, the force of the explosion will fix the metal to the glass, that it cannot be wiped off, or even be affected by any of the common menstrua, which would otherwise dissolve it. If a smooth piece of metal, or semi-metal, be fixed on each of the wires, that bear the knobs D, D, and their surfaces be brought near each other, so that the battery may be discharged through them, by connecting one wire of the discharger with the outside of the battery, and the other wire with the inside of it, each surface will be marked with a central spot, and concentric circles, which are more or less distinct, and more or less in number, as the metal upon which they are marked requires a greater or less degree of heat to melt it, and as a greater or less force is employed. If a plain piece of metal be fixed on one of the wires, and a sharp-pointed needle on the other, directed to the surface of the metal, the explosion of a battery repeatedly passed from one to the other, will gradually mark the surface of the metal, opposite to the point, with circles consisting of all the prismatic colours, the coloured rings will appear sooner, and be closer to one another, as the point is nearer to the surface of the metal; and the number of rings depends on the acuteness of the point. See CIRCULAR SPECTRUM COLOURS, and FAIRY CIRCLES.

DISCIPLE, from *discipulus*, one who learns any thing from another. Thus the followers of any teacher, philosopher, &c. are called *disciples*. In the Christian sense, they were the followers of Jesus Christ; in general; but in a more restrained sense, the *disciples* denote those alone who were the immediate followers and attendants on his person; of which there were seventy, or seventy-two. The names *disciple* and apostle are often synonymously used in the gospel history; but sometimes the apostles are distinguished from *disciples*, as persons selected from them, to be the principal ministers of his religion; of these there were only twelve. The Latins keep the festival of the seventy, or seventy-two *disciples*, on July 15; and the Greeks on January 4.

DISCIPLINE primarily signifies instruction and government; but the word is figuratively applied to a fixed method of living, according to the rules of some profession.

We say the *military discipline*, the *ecclesiastical* or *church discipline*, the *regular* or *monastic discipline*, &c.

We do not say *civil discipline*, but instead thereof *polity*.

DISCIPLINE is also used in a peculiar sense for the chastisement, or bodily punishment, inflicted on a religious, who has been caught delinquent; or even for that which the religious voluntarily undergo, or inflict on themselves, by way of mortification.

Among all the austerities practised by the ancient monks

and solitaries, Dupin observes, there is no mention made of *discipline*: in effect, it does not appear to have been in use in antiquity, unless to punish the monks who had been taken tripping.

It is commonly said to be St. Dominic, and Peter Damian, who first introduced the use of *discipline*; but F. Mabillon notes, that Guy, abbot of Pomposi, and others, had practised it before them. It is pretty certain, the practice was first established in the eleventh century, with design to redeem the penances the canons imposed on divers offences; and at length they came not only to redeem for themselves, but also for others. See F. Mabillon.

DISCIPLINE is also frequently used for the instrument wherewith a monk chastises, or mortifies himself; which is usually made of ropes, knotted hair, or twisted parchment; sometimes of broken rods. St. Jerom is painted with *discipline* of iron chains, armed with spun-rowsels, &c. See FLAGELLATION.

DISCIPLINE, *Basil's*, in the *History of the Church of Scotland*, is a common order, drawn up by the assembly of ministers in 1650, for the reformation and uniformity to be observed in the *discipline* and policy of the church. In this book the government of the church by prelates is set aside, church-sessions are established, the superstitious observance of fast-days and fairs days is condemned, and other regulations for the government of the church are determined. This book was approved by the privy-council, and is called the first book of *discipline*.

DISCIPLINE, *military*, denotes the exercise of those laws that are established for regulating the conduct of military men.

DISCIPLINE, *marine*, signifies the training up soldiers for sea-service; in such exercises and manoeuvres as can be performed on board ships of war at sea.

DISCLAIMER, in *Law*, a plea, containing an express denial, renouncing, or *disclaiming*, of a thing alleged. As if the tenant sue replevin upon a distress taken by the lord, and the lord show the taking, saying, that he holds of him as his lord; and that he disclaimed for rent not paid, or service not performed; then the tenant, denying to hold of such lord, is said to *disclaim*, and the lord proving the tenant to hold of him, the tenant loses his land.

Also a man, denying himself to be of the blood, or kindred of another, in his plea, is said to *disclaim* his blood. If a man arraigned of felony, *disclaim* goods; being cleared, he loses them.

Thus likewise in chancery, if a defendant by his answer renounces having any interest in the thing in question, this is a *disclaimer*: to which may be added, a *disclaimer* by renouncing an executorship of a will, or the right to an administration.

DISCLOSED, a term used for chickens or hawks newly hatched; also for buds or flowers just blown.

DISCOBOLII, *Ancient*, from *Discus* and *Bolus*, *throwers*, among the *Ancients*, an appellation given to those who gained the victory at the *discus*. See *DISCUS*.

DISCOIDES *fungi*, in *Natural History*, the name of a genus of the echinodermata, or sea hedge-bogs; the periphery of the base of these is exactly round, and the body of a convex-concave figure. The principal species of this genus is the *subulcus*, which has sometimes a reticulated top, the lines being very neat and elegant, sometimes a plain and smooth top; sometimes it is all over covered with extremely minute and fine *striæ*; and sometimes it is much flatter than at others. Klein's Echinoderm.

DISCONTINUANCE, an interruption, intermission, or cessation, of the course of a thing: as, *discontinuance* of possession, of a plea, process, &c.

The effect of a *discontinuance of possession* is, that a man may not enter on his own land, or tenement alienated, whatever his right be to it, of himself, or by his own authority; but must bring his writ, and seek to recover possession by law. As if a man alien the lands he holds in right of his wife; or a tenant in tail make any feoffment, or lease for life not warranted by the stat. 32 Hen. VIII. by fine, or livery of seisin; such alienations are called *discontinuances*.

The effect of *discontinuance of process*, is, that the opportunity of prosecution is lost, and not recoverable, by beginning a new suit. Not to be *discontinued*, and to be put off without a day, are the same thing; and it is nothing less than to be finally dismissed the court.

Discontinuance of process, in *Common Law*, is helped by appearance; and by statute 32 Hen. VIII. cap. 30. all *discontinuances*, miscontinuances, and negligences therein, of plaintiff or defendant, are cured after verdict.

DISCONTINUANCE of plea, is when divers things should be pleaded to in a suit or action, and some are omitted. If

a defendant's plea answers to part only, it is a *discontinuance*; and the plaintiff may take judgment by *nil dicit*, for that which is not answered; but if the plaintiff plead over, the whole action is *discontinued*.

If a justice-seat be discontinued by the not coming of the justices, the king commonly renews the same by his writ, &c.

DISCORD, in Music, the relation of two sounds, which are always, and of themselves, disagreeable, whether applied in succession or consonance.

If two simple sounds be in such a relation of tune, that is, have such a difference of tune, as that, being sounded together, they make a mixture, or compound sound, which the ear receives with displeasure, it is called a *discord*, as, on the contrary, if it receive it with pleasure, it is called a *concord*; and whatever two sounds make an agreeable, or disagreeable compound, they will have the same effects respectively, if they be applied in succession.

As concords are denominated harmonical intervals, so may *discords* be denominated unharmonical intervals.

Discords are distinguished into *consonants*, and *inconsonants* intervals.

DISCORDS, consonants, by the ancients called *semili*, are such as are apt, or fit for music, next to, and in combination with concords. These are relations, which in themselves are neither very agreeable, nor very disagreeable, and have only a good effect in music by their opposition, as they heighten and illustrate the more natural and essential principles of the pleasure we seek for; or, as by their mixture, and combination with them, they produce a variety necessary to our being better pleased.

Notwithstanding this, they are still called *discords*; as the bitterness of some things may help to set off the sweetness of others, and yet they may still be bitter.

DISCORDS, inconsonants, by the ancients called *emili*, are such as are never chosen in music; as having too great a harshness in them, though even the greatest *discord* is not without its use.

The essential principles of harmony, harmonical intervals, or concords, are but few, in number only eight; the infinite number of other ratios are all *discords*. Hence Mr. Makenzie shows the necessity of taking some of the less upward of these *discords* into the system of music. In order to this he considers the effect of having none but harmonical intervals in the system of music.

1. With respect to a single voice: if that should move always from one degree of tune to another, so as every note, or sound to the next, were in the ratio of some concord; the variety, which is the life of music, would soon be exhausted. For to move by no other than harmonical intervals, would not only want variety, and so weary us with a tedious repetition of the same things, but the very perfection of such relations of sounds would cloy the ear, in the same manner as sweet and luscious things do the taste; which, for that reason, are artfully seasoned with the mixture of sour and bitter.

2. With respect to music in parts, i. e. when two or more voices join in consonance, the general rule is, that the successive sounds of each be so ordered, that the several voices shall be all concords. Now there ought to be a variety in the choice of these successive concords, and also in the method of their successions; all which depends on the movement of the single parts. So that, if these could only move in an agreeable manner by harmonical distances, there are but a few different ways wherein they could move from concord to concord; and hereby we should lose much of the ravishment of sounds in consonance. As to this part then, the thing demanded is a variety of ways, whereby each single voice, or more in consonance, may move agreeably in the successive sounds, so as to pass from concord to concord, and meet at every note in the same, or a different concord, from what they stood in at the last note.

In what cases, and for what reasons, *discords* are allowed, the rules of composition must teach; but only joining these two considerations, &c. we see how imperfect music would be without any other intervals than concords.

Beside the *consonant discords*, used designedly in music, there are several other *discord* relations, which happen unavoidably, in a kind of accidental and indirect manner. Thus, in the succession of several notes, there are to be considered not only the relations of those which succeed others immediately, but also of those betwixt which other notes intervene. Now the immediate succession may be conducted so as to produce good melody; yet among the distant notes there may be very gross *discords*, that would not be tolerable in immediate succession, and far less in consonance. And such *discords* are actually contained in the scale of music. Thus, taking

any one species, e. gr. that with the greater third, and marking the degrees betwixt each term and the next; though the progression be melodious, as the terms refer to one common fundamental, yet there are several *discords* among the mutual relations of the terms; e. gr. from 4th to 7th *g*, is 3:2: 4:5; and from 2d *g* to 6th *g*, is 2:7: 4:1; and from 2d *g* to 4th, is 2:3: 3:4; all *discords*.

The species of counterpoint, wherein there is a mixture of *discords*, is called *figural counterpoint*; of which there are two kinds; that wherein the *discords* are introduced occasionally, to serve as transitions from concord to concord; and that wherein the *discord* bears a chief part in the harmony.

Discords may transiently pass upon the unaccented parts of the measure, without any offence to the ear: this is called *suspension*, because the transient *discord* supposes a concord immediately following.

The harmony of *discords* is that wherein the *discords* are made use of as a solid and substantial part of the harmony. For, by a proper interposition of a *discord*, the succeeding concords receive an additional value. Thus the *discords* are in music what the strong shades are in painting.

The *discords* are the 5th when joined with the 6th; the 4th joined with the 5th; the 6th is of its own nature a *discord*; 6:5 is the 7th.

These *discords* are always to be introduced into the harmony with due preparation, and must be succeeded by concords; which is commonly called the *resolution of the discord*. The *discord* is prepared by substituting first in the harmony in quality of a concord, that is, the same note, which becomes the *discord*, is first a concord to the bass-note immediately preceding that to which it is a *discord*.

The *discord* is resolved by being immediately succeeded by a concord descending from it by the distance only of greater 2d, or lesser 2d.

DISCORDS, appell. of, poemum discordia, a phrase used to signify the subject, or occasion of some misimagination in a society. It is borrowed from the heathen mythology; the poem *sciron*, that at the marriage of Thetis and Peleus, the guests of *discord* threw a golden apple, wherein were written these words, *to the fairest*; which immediately stirred up a dissension between Juno, Pallas, and Venus, each pretending a title to the apple.

DISCOVERT, in Law, denotes an unmarried woman.

DISCOVERY, in Law, the act of revealing or disclosing any matter by the defendant, in his answer to a bill filed against him in a court of equity.

DISCOVERY of accomplices is provided for in the cases of robbery, burglary, house-breaking, and larceny, to the value of five shillings, from shops, ware-houses, stables, and coach-houses, by 4 and 5 W. and M. cap. 8. 10 and 11 W. III. cap. 23. and 5 Anne, cap. 31. which enact, that if any such felon, being out of prison, shall discover two or more persons who have committed the like felonies, so that they may be convicted, he shall in most cases receive a reward of 40*l*. and in general be entitled to a pardon of all capital offences, excepting only murder and treason. And if any such person having feloniously stolen any lead, iron, or other metals, shall discover and convict two offenders of having illegally bought or received the same, he shall by stat. 29 Geo. II. cap. 30. be pardoned for all such felonies committed before such discovery.

DISCOVERY by homi. cap. See CERTIFICATE of Bankruptcy, and PETITION of Bankruptcy.

DISCOVERY, in Dramatic Poetry, a manner of unravelling a plot or fable, very frequent in tragedies, comedies, and romances; wherein, by some unforeseen accident, a discovery is made of the name, fortune, quality, and other circumstances of a principal person, which were before unknown.

A discovery should never be in vain, by leaving those who thus discovered one another in the same situation and sentiments they were in before: in effect, those *discoveries*, which are immediately followed by a peripetia, or change of fortune of some principal character, wherein the unravelling depends, are always the most beautiful.

One of the finest *discoveries* ever brought upon the stage, is that of Oedipus in Sophocles; for the minute he finds himself the son of that Jocasta, who was then his wife, he becomes of the most happy, the most miserable of all men. There are three sorts of *discoveries*: the first by certain marks in the body, either natural, or accidental: such is that of Ulysses, who having received a wound in the thigh by a boar, before the Trojan war, is discovered by the old nurse, upon washing his legs after his return home incognito.

The second by tokens: as the calyx of things, which the priests found with Ion when he was exposed, discovers Creusa, whom he was going to kill, to be his mother.

The

The third is made by remembrance: that is, when the sight or hearing of any thing occasions us to recollect our misfortunes. Thus, when Ulysses heard Democleus telling his actions at Troy, the memory of them struck him, and drew tears from his eyes, which discovered him to Alcinoüs.

But the finest sort is, that which arises from the subject, or incidents of the fable; as that of Oedipus from his excessive curiosity, and the letter that Iphigenia sent by Pyrrhus.

DISCOUNT, in Commerce, a sum deducted, or retained in hand, upon paying a greater. See **DEDUCTION**.

The term is much used among mechanics, and manufacturers, who keep workmen, journeymen, labourers, &c. for the sum advanced them before-hand, which are discounted when the payments are made in course.

DISCOUNT is more particularly used for an allowance made on a bill of exchange, or any other debt not yet become due; to induce the acceptor, or debtor, to advance the money.

In the usual mode of calculating this discount, it is supposed that the whole interest which might be made of the debt till it becomes payable, should be discounted: but this is not just; for though it be true, that from this time to the time when the debt becomes due, such interest might be made of it, yet it is not true, that by paying the whole debt without discount, the debtor loses so much at this time as that interest; because he cannot be said to have lost it, till the time comes when he should receive it; and therefore he cannot be said to lose any more at this time than such a sum, as being laid out at interest from this time till the time of payment of the debt would amount to the interest of the debt for the same time: in order to obtain this sum, find the amount of $1l.$ for the given time, which at the rate r and for the time t , will be $1 + rt$. See **INTEREST**. And rpt is the interest of the principal p for the same time; therefore $1 + rt : 1 :: rpt : \frac{rpt}{1 + rt}$, which is the discount required.

Or, otherwise, find a principal, which, being laid out at a certain rate of interest for the given time of discount, will amount to the debt: this principal is its present worth, and the difference between this and the debt is the true discount. Thus $1 + rt : 1 :: p : \frac{p}{1 + rt}$; and $p - \frac{p}{1 + rt} = \frac{prt}{1 + rt}$ the true discount as before. Hence we have the following rule: divide the continual product of the debt, rate and time by the sum of 1 , and the product of the rate and time. To find the annual discount at 3 per cent. divide 3 by 1.03 ; at 3½ per cent. 3.5 by 1.035 ; at 4 per cent. 4 by 1.04 , &c. and the several quotients will be the discounts required. Thus,

At 3 per cent. the discount is .0291,7621,3592.

3½	-	-	.0338,1642,5121
4	-	-	.0384,6153,8462
4½	-	-	.0430,6220,0957
5	-	-	.0476,1924,7619
6	-	-	.0566,0377,3585
8	-	-	.0740,7407,4074
10	-	-	.0909,0909,0909

The discount of $1l.$ for one year multiplied by any principal will give the annual discount of that principal: e. g. the discount of $100l.$ for a year at 5 per cent. is $4.7619l.$ &c. or $4l. 15s. 2d. 4$; and $95l. 4s. 4d. 4$ will amount to $100l.$ in a year at this interest: whereas it is the common practice to allow $5l.$

The discount on any debt for one year being found equal to $\frac{prt}{1 + rt}$, at $t=1$, Dr. Harris in his Lexicon directs to find the discount of the same debt for any part of one year, by taking the proportional part answering to the time, as the 35th part of the whole discount for that of a year, &c. But it is easy to perceive the erroneous nature of this rule, as well as of the tables which he has given founded upon it. By his rule $1 : \frac{prt}{1 + rt} :: t : \frac{prt}{1 + rt}$

instead of $\frac{prt}{1 + rt}$ the discount required: the former quantity is evidently less than the latter, if t be a fraction, but greater when t is a whole or mixt number. The following rule, by which Mr. Smart has constructed his tables, which are the most accurate of this kind, will give a similar result with the theorem already proposed. Find the interest of $1l.$ for any day or number of days, at any given rate; then divide unit by the sum of 1 , and its interest; and the arithmetical complement of the quotient will be the required discount. Example at 5 per cent.

$1l.$ with its interest for 1 day is $1.0001,3699$
 $2 - 1.0002,7397, &c.$

Then divide unit by	The quotients are,	And arithmetical complements,	Discounts of $1l.$ for 1 day
1.0001,3699	.9998,6303	.0001,3697	2
1.0002,7397	.9997,2601	.0002,7399	4
1.0004,1095	.9995,8921	.0004,1079	3
1.0005,4795	.9994,5235	.0005,4705	4
1.0006,8493	.9993,1554	.0006,8446	5
1.0008,2191	.9991,7856	.0008,2124	0
1.0009,5890	.9989,4202	.0009,5798	7
1.0010,9589	.9988,0533	.0010,9496	8
1.0012,3288	.9987,6864	.0012,3196	9
1.0013,6986	.9986,3201	.0013,6899	10
1.0015,0685	.9984,9549	.0135,351	100
1.0017,4383	.9983,5897	.0160,6007	250

Thus a table of discount may be formed for any number of days. See such a table at twelve several rates in Smart's Tables, 4to edit. See also on this subject Malcolm's Arithm. book vi. chap. 10.

Discounts are also frequently given for the payment of debitors, or bad debts.

DISCOUNT is also used among merchants when they buy commodities on trust, with a condition, that the seller shall discount so much with him per cent. for each payment made before the time expired. See **PROMPT PAYMENT**.

The Sieur de la Porte distinguishes between these two kinds of discount: the first, or that upon bills of exchange, is reckoned like the exchange, at the rate of so much per cent. E. g. At 2 per cent. discount on a hundred pounds, there is only ninety-eight pounds to pay: whereas that on commodities, is not only laid on the hundred pounds, but on the hundred and discount added together. So that discounting for goods at 10 per cent. there is only eight shabed on a hundred and eight, and not on the hundred. This last, he says, is the true discount.

DISCOUNT is also used with less propriety for the tare, or waste of any commodity, fum, &c.

DISCOURSE, in Logic, from *discursus*, I run over, an operation of the human mind, whereby it passes or proceeds from one thing to another, that is, from a known thing to an unknown.

The schoolmen define it an act of cognition, whereby the mind deduces one thing from another: this it does, when, in consequence of an assent given to one proposition, it yields assent to another: so that discourse consists in a dependency of assents; and supposes such an order between the acts, that that belonging to the consequent arises from that belonging to the antecedent. So that the intellect is then said, *discursare*, to discourse; when, from an assent to one or more propositions, it infers or draws an assent to another.

The object of discourse, therefore, or that about which the intellect is employed in discoursing, is the connexion of extremes considered with regard to some third, or medium: thus, when it judges, that every reasonable animal is risible, affirming, that there is a connexion between risibility, and rationality; and then finds, there is likewise a connexion betwixt man and reasonable animal; and afterwards gathering from the connexion found between risible and man, with rational, that man and risible have likewise a connexion, as both are connected with rational; it is said to discourse.

Hence it appears, that discourse, whereon men used to value themselves, does really betray the infirmity of the human understanding: as it denotes a chain or scale of several successive acts of cognition necessary to arrive at a truth. So that there is no discourse in God, who understands all things originally and truly. See **REASONING**.

DISCOURSE, in Rhetoric, is used in the same sense with oration.

DISCOURS FLEUR. Botanists reckon two classes of plants with a *discours fleure*. 1. Such as have the flower compounded, and the seed papous, but the leaves and stalks not milky when broken. 2. The corymbiferous plants, whose flowers are compounded into a *discours* figure, but their seeds not papous. Of the former kind are the flea-banes, ragworts, groundfells, &c. and of the latter are daisies, chamomile, tansy, wormwood, &c. There are distinctions founded by Mr. Ray, but not regarded by the later botanists.

DISCRETE, or **DISJOINT**, *Proportion*, is when the ratio between two or more pairs of numbers, or quantities, is the same, and yet there is not the same proportion between all the four numbers.

Thus, if the numbers 6 : 8 :: 3 : 4 be considered; the ratio between the first pair, 6 and 8, is the same as that between 3 and 4, and therefore these numbers are proportional: but it is only *discretely*, or *disjunctly*; for 6 is not to 8, as 8 to 3; that is, the proportion is broken off between

between 3 and 3, and is not continued all along, as it is in the following, which are called *continual proportionals*, viz. 3:6::12:24.

DISCRETE Quantity, is such as is not continued and joined together.

Such is a number, whose parts, being distinct units, cannot be united into one *continuum*; for in a *continuum* there are no actual determinate parts before division, but they are potentially infinite; therefore it is usually and truly said, that continued quantity is divisible in infinitum. See CONTINUITY.

DISCRETION, in *Law*, the faculty of discerning between right and wrong; and therefore whoever hath power to act as *discretion*, is bound by the rule of reason and law. 2 Inst. 56. 298. Infants, &c. under the age of *discretion*, are not punishable for crimes; and want of *discretion* is a good exception against a witness. 2 Hawk. 434. See AGE, and INFANCY.

DISCRETION, in the *Italian Music*, is used to direct the finger or player to execute his part with care diligently.

DISCRETIVE Propositions, are those where various judgments are made, and denoted, by the particles *but*, *nevertheless*, or by words of the like nature, either expressed or understood. Thus, fortune may deprive me of my wealth, but not of my virtue; they, who cross the seas, change their climate, but not their disposition; are called *discretive propositions*.

DISCUS, among the *Ancients*, a name given to a round shield, consecrated to the memory of some famous hero, and hung up in the temples of their gods, as a trophy of some great action.

From the figure of this *discus*, or rather of that which the Greeks and Romans used to direct themselves with, especially at their public games, and which was a round quail of brass, comes the word so much in use among astronomers, viz. the *disc* of the sun, or moon. See DISC.

DISCUS, **DISCUS**, or **DISCIFORMIS Cometa**, a comet or fiery meteor resembling a round dish or platter. The chief of this kind is called a solar comet, from the likeness of its rays to those of the sun; it is called also *lyca* and *chryseus*, from its bright silver colour mixed with a golden or amber one.

DISCUSSION, in matters of literature, signifies a clear treating or handling of any point, or problem. The usual imports a taking off, or dispelling the difficulties and obscurities with which a thing was embarrassed. We say, such a point was well *discussed*, when it was well treated of, and cleared up.

DISCUSSION is also used, in a medicinal sense, for a dispersing the matter of any tumor, or swelling, through the pores of the body; or an evacuation of some thin matter gathered in any part, by insensible perspiration.

DISCUSSORIA, *Disquisitio*, *Disaggregatio*, *discutienti*. See DISCUTIENTS.

DISCUTIENTS, in *Medicine*, either repellents or remedies proper to open the pores, and evacuate the redundant or peccant humours of the body by insensible perspiration or otherwise.

Discutienti are in this last sense the same with what we otherwise call *diaphoretics*.

DISDIAPASON, in *Music*, a compound concord, in the quadruple ratio of 4 to 1, or of 8 to 2.

The *disdiapason* is produced when the voice goes from the first tone to the fifteenth, and may be called a *sextum*.

The voice ordinarily does not go farther than from its first tone to the *disdiapason*; i. e. it does not go beyond the compass of a double octave; for the *disdiapason* is an octave doubled. It may sometimes rise several tones above a *disdiapason*, but the effort or struggle disfigures it, and makes it false. In reality, the ancient scale, or diatagma, only extended to a *disdiapason*.

DISDIAPASON-Disparis, in *Music*, a concord in a sextuple ratio of 3 to 2.

DISDIAPASON-Disfartia, a compound concord in the proportion of 16 to 3.

DISDIAPASON-Disipa, a compound consonance in the proportion of 10 to 2.

DISDIAPASON-Semidiatia, a compound concord in the proportion of 14 to 3.

DISEASE, in *Medicine*, that state of a living body, wherein it is prevented the exercise of any of its functions, whether vital, natural, or animal. See *Acute* and *Chronic Disease*.

Or, *disease* is an indispotion contrary to nature, whereby the action of some part is immediately injured.

Or, *disease* is a depraved and disorderly state of the solid, and fluid parts; whereby all, or some of the functions, either of the body, or mind, or both, are either abolished, or impaired.

VOL. II. N° 99.

An ingenious author of a late Latin treatise, *De Purpatione*, holds the essence of a *disease* to consist in a want of that equilibrium between the solid and fluid parts, which is necessary to the maintenance of health; others add, that all *diseases* arise either from too lax, or too strict a tension of the fibres.

Of all animals, man is subject to the most *diseases*; and of men, the studious and speculative are most exposed thereto. Other animals have their *diseases*; but they are in small numbers: nor are plants without them; though their maladies scarce exceed half a score. The ancients deified their *diseases*. Volusius De Idolis. lib. viii. cap. 5. Some *diseases* only impair the use of the part immediately affected; as the ophthalmia, gout, &c. Others destroy it entirely; as the *gutta serena*, palsy, &c. Some affect the whole body; as the fever, apoplexy, epilepsy, &c. Others only impair a part; as the asthma, colic, dropsy, &c. Some only affect the body; as the gout; others disturb the mind; as melancholy, delirium, &c. Lastly, others affect both the body and mind; as the mania, phrensy, &c.

The colder the country, in general, the fewer and the less violent are the *diseases*. Scheffer tells us, that the Laplanders know no such thing as the plague or fevers of the burning kind, nor are subject to half the distempers we are. They are robust and strong, and live to eighty, ninety, and many of them to more than a hundred years; and at this great age, they are not feeble and decrepit, as with us, but a man of ninety is able to work, or travel, as well as a man of sixty with us. They are subject, however, to some *diseases* more than other nations: thus they have often distempers of the eyes, which is owing to their living in smoke, or being blinded by the snow. Pleuritis and inflammations of the lungs are also very frequent among them; and the small-pox often rages with great violence. They have one general remedy against these, and all other internal *diseases*: this is the root of that sort of moiss, as Scheffer expresses it, which they call *jertih*. They make a decoction of this root in the whey of rein-deer milk, and drink very large doses of it warm to keep up a breathing sweat; if they cannot get this, they use the stalks of angelica boiled in the same manner: they have not to great an opinion of this as of the other remedy; but the keeping in a sweat, and drinking plentifully of diluting liquors, may go a great way in the cure of their *diseases*, whether either the one, or the other of the drugs, have any virtue or not. They cure pleuritis, by this method, in a very few days; and get to well through the small pox with it, that very few die of it.

It has been always observed, that people of particular paces were peculiarly subject to particular *diseases*, which are owing to their manner of living, or to the air, and effluvia of the earth and waters. Hoffman has made some curious observations on *diseases* of this kind. He observes, that swellings of the throat have always been common to the inhabitants of mountainous countries; and the old Roman authors say, Who wonders at a swelled throat in the Alps? The people of Switzerland, Carinthia, Styria, the Harz forest, Transylvania, and the inhabitants of Conflant, he observes, are all subject to this *disease* from the same cause. See BRONCHOCLE.

The French are peculiarly troubled with fevers, with worms, and with hydrocles and farsecles; and all these disorders seem to be owing originally to their eating very large quantities of cheusons. The people of our own nation are peculiarly afflicted with hoarseness, catarrhs, coughs, dysenteries, consumptions, and the scurvy; and the women with the *flux albus*, or whites; and children, with a *disease* scarce known elsewhere, which we call the rickets. In different parts of Italy, different *diseases* reign. At Naples, the venereal *disease* is more common than in any other part of the world. At Venice, people are peculiarly subject to the bleeding piles. At Rome, tertian agues, and lethargic distempers are most common. In Tuscany, the epilepsy, or falling sickness. And in Apulia they are most subject to burning fevers, pleuritis, and to that sort of madness which is attributed to the bite of the TARANTULA, and which, it is said, is only to be cured by music.

In Spain, apoplexies are common, as also melancholy, hypochondriac complaints, and bleeding piles. The Dutch are peculiarly subject to the scurvy, and to the stone in the kidneys. Denmark, Norway, Sweden, Pomerania, and Livonia, are all terribly afflicted with the scurvy; and it is remarkable, that in Denmark, Sweden, and Norway, fevers are very common; but in Iceland, Lapland, and Finland, there is scarce ever such a *disease* met with; though peripneumonies are very common in these places, as also *diseases* of the eyes and violent pains of the head. The Russians and Tartars are afflicted with ulcers, made by the cold, of the nature of what

we call chilblains, but greatly worse; and in Poland and Lithuania there reigns a peculiar *dysæsthesia*, called the *plaga Pavia*, so terribly painful and offensive, that scarce any thing can be thought of worse.

The people of Hungary are very subject to the gout and rheumatism: they are also more infested with lice and fleas than any other people in the world, and they have a peculiar *dysæsthesia* which they call *crura*.

The Germans, in different parts of the empire, are subject to different reigning *dysæsthesia*. In Westphalia, they are peculiarly troubled with peripneumonies and the itch. In Silesia, Franconia, Austria, and other places thereabout, they are very liable to fevers of the burning kind, to bleedings at the nose, and other hemorrhages; and to the gout, inflammations, and consumptions. In Misnia they have purple fevers; and the children are peculiarly infested with worms. In Greece, Macedonia, and Thrace, there are very few *dysæsthesia*, but what they have, are principally burning fevers and phlegmasies. At Constantinople the plague always reigns; and in the West Indian Islands, malignant fevers, and the most terrible colics. Their *dysæsthesia* are called *endemia*. As the actions, or conditions of the body, so also the *dysæsthesia*, or defects thereof, may be reduced to three general heads; viz. 1. *Dysæsthesia* of the solid parts. 2. Those of the fluid parts. And, 3. *Dysæsthesia* compounded of both.

A popular syllabus of *dysæsthesia* may be given, as follows: the solid parts, i. e. the bones and flesh may be disordered five ways; viz. they may be rendered turbid by tumors; cut with wounds; corroded by ulcers, or caries; removed out of their place, as in hernias, prolapsoes, and dislocations; or discontinued by fractures, and contusions.

Dysæsthesia of the fluids are either in the mass of the blood, or the spirits; those of the blood are reducible to two kinds: those that thicken and inspissate, or which amounts to the same, retard its motion; and those which attenuate, and dissolve, and of consequence accelerate it. To this latter kind belong fevers, and febrile affections alone: all the other diseases of the blood belong to the former.

In too thick a state of the blood, its principles are too crass, and its molecules too big; whence a lentor, lazy motion, and even stoppage, particularly in the sinuous passages of the glands; and hence obstructions, inflammations, scirrhus, sarcomas, verrucae, pulsules, oedemata, intumescences, and other tumors, and congestions, both in the viscera and habit of the body: and hence, again, drowsiness, melancholy, hypochondriacal affections, &c. If this thick blood be too much replete with sharp acid salts, it will destroy the texture of the parts, and break out in ulcers; as in phthisical, scrophulous, scorbutic, and venereal *dysæsthesia*, gangrenes, carbones, cancers, and other erosive tumors, according to the quality and degree of saltness and acrimony; and from the same source arise cephalalgias, cardialgias, colics, gouts, rheumatism, pleuritis, &c. which by abrading the solid substance, frequently emaciate the body.

The *dysæsthesia* of the animal spirits arise either, 1. From an intermission, or retardation of their motion; or a diminution of their quantity; or, 2. From a disorder in their crass, or quality.

To the first class are reduced the catalepsia, apoplexy, coma, carus, palsy, stupor, tremor, &c. To the second belong the mania, phrensy, delirium, fossilancti, melancholy, vertigo, insania, epilepsy, hysterical affections, horror, &c. Add, that as all *dysæsthesia* of the blood arise from external causes, viz. some one, or more, of the non-naturals, as food, air, evacuation, &c. so those of the spirits generally proceed from disorders of the blood. Lastly, the *dysæsthesia* of the fluids, whether those in the blood, or spirits, are seldom confined long thereto; but they presently come to disturb and impede some of the functions of the solid parts; and, at last, corrupt the substance of the solids themselves. Hence compound, or complicated *dysæsthesia*, which are infinitely various.

The learned Boerhaave furnishes us with a much more accurate and scientific division of *dysæsthesia*, into those of the solids and fluids.

DISEASES of the solids he considers, either as of the simple and similar parts, or of the organical.

DISEASES, Similar, are, 1. Those of the last and smallest fibres; which are reducible to too great tension, and laxness, too great strength, or weakness, and a solution of their continuity.

2. Those of the membranes, which, being only assemblages of the fibres just mentioned, are subject to the same disorders.

3. Those of the last and smallest canals, which are formed of such membranes.

4. Of the membranes composed of such canals.

5. Of canals, composed of such membranes, which are all the greater vessels of the body.

6. Of the solid parts, which are composed of canals, compressed and grown together, so as to be void of humour to distend them; or canals growing into one consistent part, the humour hardening together with the vessel that contained it.

Lastly, Supposing these parts all found, *dysæsthesia* may befall them with respect to their structure, from a vice, or vicious application, of the matter of nutrition.

DISEASES, Organical. An organical part, consisting of the several simple parts above mentioned, and fitted to perform any office, by means of some humour contained in it, may be considered, either in itself, as a solid part, or with respect to the humour it contains. In the first view, organical *dysæsthesia* are reducible to four classes.

1. Disorders in the figure, and the circumstances thereof, as roughness, solidity, cavity, &c. To this belong the aneurysms, when one vessel opens into another; the anastomosis, when a rupture is made; the *apertures*, when a breach is occasioned by corrosion; the *spasms*, when is a total obstruction of the cavity, by a viscous granulous matter; the *stricture*, or narrowness of the passage; the *stricture*, or compression of the sides of the cavity; the *stricture*, when the sides are quite joined; and *varicosities*, when the vessel is so emptied, that the sides falling together, the cavity is lost. See DIAPHRAGMS, DIAPHRAGMA, &c.

2. In the number, where it is either deficient or redundant; but the parts seldom err in this respect, so as to occasion a *dysæsthesia*.

3. In magnitude, to which belong nodes, exostoses, and calluses.

4. In the situation, and connexion; as, when the ligaments are too long, or too short, when broken, or overgrown; also distortions, luxations, subluxations, hernia, or ruptures in the groin; scrotum, bladder, prostaticus of the womb, bladder, and rectum; disorders of the tendon, and muscles, particularly their flying out of their places; the relaxation, or rupture of the membranous ligament that should retain them.

Lastly, There is a *dysæsthesia*, common both to similar and organical parts, called solution of continuity.

DISEASES of the fluids, considering these fluids simple, and in themselves, may be reduced to disorders in respect of quantity and quality; but considering them as contained in solids, they may err too, in place and proportion.

As to the first, such an abundance of the humours as disturbs the animal functions, is called a plethora; and as to *dysæsthesia* from the defect of humours, we scarce know of any.

As to the second, such quality of the humours as disturbs the animal functions, is called cacochymia. Now, this is either in the fluids, considered in themselves, their own parts, and composition; or considered as they concur towards constituting some part of the body.

If the morbid quality be considered in the particles of the humour, it must either consist in an augmentation of bulk, whence the emphysemata, atrophy, lymphitis, and synxetis; or in the diminution thereof, as in the dyspnea, and anæmia; or an increase of solidity, whence too great an attenuation; or a decay thereof, whence a lentor, stagnation, and cohesiveness or in the figures, as when of spherical, it becomes angular, and consequently, with respect to the part it is applied to, sharp; whence acrimones, both acid, alkaline, muriatic, ammoniac, saponaceous, vitriolic, &c. and elasticities; or in rigidity, and flexibility; or in elasticity; or in cohesion, and divisibility. See ATROPHIA, &c.

Again, all the juices being considered together, the principal disorders they are subject to, are, too great fluidity, or tenacity; or too much velocity in their vessels, or too little.

Lastly, considering the fluids as contained in the solids, there arise divers *dysæsthesia*, merely from their changing of place: these may be reduced to two classes, viz. the grosser humours, intruding themselves into the finer canals; and the humours, extravasating, or getting out among the solid parts; whence inflammations, aneurysms, varices, encysted, oedemata, pulsules, dropsy, spongy swellings of the head, breast, abdomen, and uterus; and emphysemata.

Add, that the humours collected, and stagnating among the parts, grow purululent, ichorous, erob, &c. and sharp; and thus destroy the tender flamina, or follicles; whence sinuses, fistulas, ulcers, gangrenes, sphacelus, cancers, and the like.

These are the prime differences of the *dysæsthesia* of the body; and from these arise most of the rest, so that they may be regarded, not only as *dysæsthesia*, but as the crises of *dysæsthesia*. See each further explained under its respective article in this work. See also NOSTOLOGY.

Thera

There is also another division of *diseases*, in use among physicians, taken from certain external accidents, which are common to a great many different *diseases*; which distinction, too, has its use, though they generally run it too far. *Diseases* are by this distinguished, 1. With respect to their cause, into idiopathy, sympathy, protopathy, dæmonopathy, hereditary, connate, and acquired.

2. With respect to their subject, into *diseases* of old age, children, adults, men, women, maids, pregnant, parturient; and into endemical, epidemical, &c. 3. With respect to season, into vernal, autumnal, continued, and intermitting. 4. With respect to their effects, into benign, malignant, curable, incurable, mortal, and contagious. 5. With respect to their state, into beginning, progress, state, declension, and end. And lastly, With respect to duration, into most acute, which terminate in four days, acute, in twenty; and chronic, which are all those of longer continuance.

DISEASES, *Acute*, is that which terminates, or comes to its period, in a few days; or, as the physicians express it, *cito et tam prout terminatur*.

In this sense, the word stands opposed to *chronical*. All *diseases* which hold above forty days, are reputed chronic.

Dr. Quincy thinks an *acute disease* may be defined, that which is attended with an increased velocity of blood.

Acute diseases are the more dangerous, in that beside the violence of the symptoms, if there be not time to empty the *prima viæ*, it is very difficult to stop their progress, and save the patient.

Acute diseases are usually divided into those simply called *acute*; and those which, by reason of the vehemence of the symptoms, are called *most acute*.

DISEASES, *Chronic*, stand in opposition to *acute diseases*, which are speedy, and hasten to a crisis; as fevers, small-pox, &c.

Chronic diseases are usually owing either to some natural defect in the constitution, or to an irregular manner of living; and evacuation of one kind or another, is nine parts in ten of their remedy, according to Dr. Cheyne.

The sources of chronic distempers, says the same author, are, 1. Viscidity in the juices, or the over largeness of their constituent particles; which not being sufficiently broken by the conculsive powers, stop, or retard the circulation. Or, 2. Too great abundance of sharp acrimonious salts; whereby the juices themselves are rendered so corrosive, as to burst or wear out the solids. Or, 3. A relaxation, or want of due force and springiness of the solids themselves.

An excess in the quantity of our meat and drinks begets the first; the bad condition of the same foods, the second; and both together, with want of due exercise, the third.

Several authors have given us very compendious theories of *diseases*, reducing them all to some one general disaffection. Boerhaave deduces all the *diseases* of the human frame from the scorbutus; Musgrave, from the arthritis; Dr. Woodward, from the bile. Others imagine all *diseases* the effects of a virus, which has lurked in the seed ever since the sin of Adam; Helmont, and Serenus the Dane, take them to depend on some extraneous ferment, formed in or out of us. Lastly, as appearing from the observations of Pliny, Kertcher, Langius, and Bonomo, that there are little worms in several blood, pulseless, carbuncles, and the such, divers physicians have taken occasion to suspect, that all *diseases* arise from insects.

DISEASES of soldiers. See DIRT, and SOLDIERS.

DISEASES, Pueral. The chest of *puerile diseases*, for idleness, or profit sake, or for other occasional purposes, has been too common in all ages, and is too difficult to be discovered in all cases; though, in many, there are ways of coming at the truth. We have had a very late instance of a young lady, who puzzled several of our best physicians, to account for the nature of a *disease*, which showed itself in a singular kind of excoriation; and the secret perhaps had never been discovered, had not a bottle of *agua fortis* been accidentally found in her chamber; the touching the arms, &c. with which, had occasioned all the appearances, which some strange fault in the juices had been before caused of.

Disimulation in regard to *diseases*, may be reduced to three kinds. In the first, the sickness is pretended by words only, and really is not: of this nature are the pretended head-ach, colic, and the like; which as the patient can only know, the physician may always be deceived. In the second, there are not only words for testimonies of the sickness, but there appear signs and marks of it on the body, which yet are only counterfeited to serve certain purposes. Scabbiness, leprosy, and even the exulceration of the lungs may be thus counterfeited; the last by a pretended spitting of blood. Gravitation is often pretended also. Our beggars often

contrive the means of these to excite compassion. In the third kind of dissimulation of *diseases*, we are to include the concealing a *disease*, which really exists, instead of the owning of one which does not.

In the discovery of these deceptions, on which the credit of the physician often depends, it is not mere medical knowledge that will succeed, but there must be added to it a sagacity in exploring all circumstances and outward accidents and especially those things which relate to the genius, temper, and state of the person suspected. The *dæmoniacs* of former ages, exorcised by priests, who wanted to propagate the credit of their religion, or their own family, have generally been cheats of this kind, and might have been discovered by any who had talents and opportunities for the proper examinations. Sylvaticus, an Italian author, has given an excellent set of rules for the discovery of these frauds, and all others of pretended sicknesses, to which we refer the curious reader.

DISEASES of infants. See INFANTS.

DISEASES, Pestilential or epidemic. Many think that the cause of all these is in the air, and is exhaled in vapours through the pores of the earth.

It is generally observed, that *pestilential diseases* seize first the cattle; which is not wonderful, since they naturally carry their noses near the ground, and suck in the vapours as they rise, or feed on the herbage that is infected by them. It often happens, that the vapours do not rise so high as to affect men at all; but though in this case the plague would be naturally confined to the cattle alone, yet it gets among men by means of the food eaten by them, and before tainted with the contagion. There is no doubt but that the flesh of animals that die of *diseases*, partakes somewhat of the nature of these *diseases*; and when they are pestilential, may spread a pestilence among us, which, perhaps, would otherwise never have reached us.

The plague once begun, frequently joins itself with such other *diseases* as the people it attacks are most subject to; hence, in the northern nations, where the fevers is frequent, it is often seen that the plague and fevers appear mixed. These two *diseases*, in their nature somewhat agreeing, make each other the worse and more violent; but on the contrary, there are other *diseases* depending on such contrary causes, that the plague, if the patient survives, proves a cure to them.

Dr. Hodges instances the consumption, and the king's evil, as two diseases of this kind; which, though in themselves of the most terrible kind, and when in an advanced stage usually baffling all remedies, yet he saw persons in the plague that last raged in London, cured of both by the plague; the symptoms of the disease appearing more mild in these than in other cases, and the patients at once recovering of both complaints.

He also tells us of some people terribly afflicted with the gout for many years, who being at that time affected by the contagion, had the plague with less violent symptoms than others; and were, on its going off, cured of the gout also.

A fever is usually a concomitant symptom of the plague, but it is not an inseparable sign of it. A palpitation of the heart is another of the usual, but not constant symptoms; where this comes on, it is usually very violent, and often is so loud, that it may be heard at a considerable distance.

The plague is less contagious than is usually supposed, and those who escape the terror of it, often escape it wholly. Hodges gives us an instance of a poor woman who had the plague soon after her delivery, and suckled her young child as she lay ill of it. She had a craniocæc on her breast, near the nipple, which the child sucked at; and yet the mother recovered, and the child never caught the infection at all; though this seemed a circumstance under which there could be no escaping.

Hodges, treating of the prognostics of an imminent plague, tells us, that one very remarkable one is the change of chronic distempers in general into acute ones, and those attended with very violent symptoms; and a murmur among the cattle happening at the same time, form together a prognostic not easily to be got over, without the terrible sequel of a general pestilence.

If the plague is very terrible at its first appearance, it never is of long duration; and on the contrary, when it comes, from a scarce perceptible beginning, more and more violent, it is generally of a long continuance. What time it takes from the beginning to the height the same it takes from the height to the final period.

The most fatal symptoms in the last plague in London, and which usually prefigured death very near, were hæmorrhages from the nose or ears, fluxes of the menstrua in women, diarrhoeas, dysenteries, and greenness and blackness of the excrement.

The first sweats coming on without giving ease, and long nauzeousness continuing afterwards, are also terrible symptoms. The pulse and urine, which are the two great things to judge by in most illnesses, in these preface nothing at all. The pulse is fallacious in the highest degree; and the urine often appears as well in the height of the plague, as while the person was in health. Among the several preservatives for particular places, the two best are the burning sweet-scented woods in the time, and some of the resins, such as frankincense and the like; the other is the firing a number of cannon every morning and evening. Hodges de Pest. See EPIDEMIC, and PLAGUE.

DISEASES of Plants. M. Tournefort, in an extensive dissertation on this subject, in the Memoirs de l'Academie des Sciences, refers all the *diseases* of plants to the following causes:

1. The too great abundance of the nutritious juice.
2. The defect, or want of this juice.
3. Some ill qualities it acquires.
4. Its unequal distribution in different parts of the plant.
5. External accidents.

The *diseases*, principally observed by our gardeners, are, 1. Barrenness, when the tree, though seeming fresh and healthy, bears no blossoms; or, if it does, they soon fall; or, if they set, the fruit drops before it comes to maturity.

2. Blasting of the buds, occasioned by a frost happening when the leaves and blossoms are wet; by this means the pores are shut, and the vital juices suffocated; when if the sun break out on a sudden, they turn yellow, with round fiery specks growing on them; whence frequently proceed tumors, like warts, which, rotting, grow full of maggots. Mr. Mortimer adds, that the want of rain in blossoming-time often occasions the dropping off of the blossoms, for want of sap; he, therefore, recommends the watering of them.

3. Consumption, proceeding from a want of sustenance, through the failure of the nourishing juices, or from obstructions of the veins and roots; or ill digestion, and secretion of humours, &c.

4. The mofs; an account of which see under the article Moss.

5. The jaundice, which, though it does not hinder the tree from appearing sound, yet, when it begins to sprout, the leaves become of a whitish green, and as they grow bigger, turn yellow: this frequently arises from external causes, as the mildew; but, chiefly, from a stony or chalky soil, impregnated with an acid salt.

6. Mildew, a kind of epidermal *disease*, most frequent and fatal in the spring season: it is properly a corrosive and nipping dew, proceeding from pent up vapours now exhaled, and returned back on the tender opening buds, which infects them by its acrimony, and obstructs the circulation of the nutritive juices; by which means the leaves begin to fade and wither, and both the blossoms and fruit are much prejudiced.

7. A thick fog, or too abundant dew, Agricola assures us, occasions the same *diseases* as the mildew, only in a less degree.

8. Falling of the leaves; which happens when the trees, sprouting too soon, are either surprised by excessive heat, or violent cold.

9. Uredo, or scorching: of which there are two kinds: the first happening from the fall of a subtile dew, or small rain, immediately followed by the piercing beams of the sun, which suddenly closes the pores, before dilated, and burns up the leaves: the second happening from the like fervour in the internal parts of the tree, viz. in the pith, occasioned by some inward failing: Agricola imputes it to the fault of the gardeners, who, in transplanting trees, frequently cut off the lesser filaments and roots, as also the greater roots, without covering the wounds with wax, or the like.

10. Scurf, or leprosy, a *disease* chiefly of the bark, caused by a too great dilatation of the pores, whereby too much perishable matter transuding, it hauges and hardens on the bark, which by this means, chaps and cracks; and thus a sort of lepra is formed, perispiration is obstructed, &c. Add, that this scurfy skin proves a harbour for vermin, which live both on the bark and tree.

11. The worm, a little animal, generated in the corrupted substance of the bark, blossoms, fruit-leaves, pith, and roots. M. Gentle mentions another kind, called cockchafers, which stick to the roots of young tender trees, and bark, and kill them. There is a third sort, called breezers, or gad-flies, which gnaw the bark. The worm is a very frequent *disease*, whereby young hopeful trees are, all of a sudden, brought to languish and decay.

12. Rotten roots, occasioned chiefly by their being planted too deep. This *disease* is incurable.

13. Blights: a particular account whereof, see under the article Blight.

Some disorders arise in the tree itself, and others in the soil and other things about it. Of the last kind are weeds, which are of the utmost ill consequence to all sorts of trees while young, and should be pulled up by hand after rain: if they are too strong rooted for this, they must be dug up; and this will have a double advantage, as the stirring the earth about their roots will do the trees very great good. When the trees are grown to any considerable height, they require no care about weeds, for they kill them with their own droppings. Suckers are another distemper of trees arising from the tree itself: they must be pulled off, or cut up close to the place where they come out, opening the earth to come at them there. Over-much wet often is a very great prejudice to trees, and especially to those kinds which naturally love a dry soil. This is to be remedied by cutting drains; and if a drip fret the body of the tree by the head (which will certainly decay it), the place must be first cut smooth, and then some loam or clay mixed well with horse-dung, is to be applied to the place, which will defend it from mischief till a new bark is formed over it. All wounds made in trees in winter are much harder to cure than those made in summer; and for these it is proper to add some tallow to the mixture of loam and dung.

When trees are barked-bound, which is easily seen by the unnatural tightness and flaking of the bark over them, it is to be remedied by cutting through the bark with a knife from the top to the bottom of the tree. This may seem a dangerous remedy to those who have not experienced it, but it never was found to do any injury to trees. It is to be done in February or March; and if the wound gape very much it may be filled up with cow-dung, which will defend the tree from injury till it heals. The digging about the root of the tree is a very good practice also on this occasion, and the cutting off of the dead or withered branches.

The grubs of beetles called teredones and cofts, which get between the bark and the tree, do great mischief; if the places can be found out where they lie, it is proper to pierce into the bark with a pointed instrument upon them, and then to open a small hole below to let out whatever moisture may be there. When trees of the fruit kind are burnt up and blistered on the bark with hot and dry seasons, and this is followed by a vast number of the puccerons or tree-lice, which feed on the juices, some recommend the boring of a large hole in the side of the tree, and pouring in some brandy, then stopping up the hole with a pin of the same wood. The tree suffers nothing by this, but the juices are so much altered for the present by it, that these animals do not like them, and consequently quit their habitations. See PUCKERON.

If a tree is by any accident barked or stripped all round, so that it cannot grow any longer, the proper method is to cut it off just above some principal branch; the stump must be cut off slanting and covered with clay, and the branch will soon become the body of a tree in the place of the other: the place where the stump is cut off being covered with a bark in the manner of a tree that is grafted.

Deer and hares, as also rabbits, are apt to bark trees, and do them great mischief. The defences against deer are by paling them round, or painting the lower part of the tree, but the first is much the better method. The hares and rabbits may be kept off by tying bands of straw round the foot of every tree as far as they can reach. Evelyn recommends the rubbing them over with human dung made into a soft paste with urine, so that it may be laid on with a brush; but this is attended with great trouble, as it must be renewed after every hard rain. Some use tar and lime mixed together, but this always damages the tree more than these creatures would have done; and in general straw-bands, where any thing is necessary, do best.

DISEMBARK, signifies to land goods from on ship-board.

DISEMBOGUE. When a ship poises out of the mouth of some great gulf or bay, they call it *disembogue*. They say, also, of a river, that at such a place, or after it has run so many leagues, it *disembogues* itself into the sea.

DIS-ERGOT, in the *Mangee*. See ERGOT.

DISFIGURING, in Law. See MAYHEM.

DISFRANCHISING, the taking away one's freedom, or privilege. See FRANCHISE.

DISGORGE, in the *Mangee*, is used for discharging or discharging an inflammation or swelling; thus, if a horse's legs are gorged or swelled, we say he must be walked out to *disgorge* them.

DISGUISE. Persons doing unlawful acts in *disguise*, are by our statutes sometimes subjected to great penalties, and even declared felons. Thus persons convicted of hunting in *disguise* in forests, parks, or warrens, or of unlawful hunting in the night, are to suffer as felons.

But

But the principal act of parliament in this respect is that commonly called the *BLACK ACT*.

DISH, in *Mining*, is a trough made of wood, about twenty-eight inches long, four inches deep, and six inches wide; by which all miners measure their ore. If any be taken selling their ore, not first measuring it by the bar-masser's dish, and paying the king's duties, the seller forfeits his ore, and the buyer forfeits for every such offence forty shillings to the lord of the field, or farmer.

DISHERISON, an old word, of the same import as disinheriting. Our lord the king, considering his own damage, and disinherison of the crown, &c. Stat. 8 Richard II. Henry IV.

DISHERITOR, a person who disinherits, or puts another out of his inheritance. The sheriff shall, forthwith, be punished as a *disheritor* of our lord the king, and his crown. Stat. 3 Edw. I.

DISJUNCT Proposition. See *DISCRETE Proposition*.

DISJUNCTIVE, something that separates, or disjoins. Thus, *or*, *either*, &c. are called *disjunctive conjunctions*; which, in connecting a discourse, do yet separate the parts thereof. E. g. *Aut Caesar, aut nullus; either Caesar, or nothing*. Hence neither advanced, nor gave back. *Disjunctive conjunctions* may also be called *partitive, distributive, and alternative*.

DISJUNCTIVE propositions, in *Logic*, are compound propositions, consisting of two members, or parts, connected by a *disjunctive conjunction*.

The first proposition of a dilemma is usually a *disjunctive proposition*.

*You must either obey the king, or be a rebel.
But you must not be a rebel.
Therefore you must obey the king.*

DISK. See *Disc*, and *Discs*.

DISLOCATION, the putting a bone out of joint, by some violence, usually called by the physicians, *luxation*. See *LUXATION*.

We have an instrument of Mr. Ercke's invention for the reduction of *dislocated shoulders*, described in the Philosophical Transactions, N^o 476.

DISMASTED, in *Sea Language*, denotes the state of a ship, when the loss her masts by engagement or bad weather.

DISMEMBERED, in *Heraldry*, is applied to birds that have neither feet nor legs; as also to lions and other animals, whose members are separated. See *MAZED*.

DISMES, *Dicimus*, in our *Law Books*, *itibus*. See *TERRE*.

DISMISSION of a bill, in *Chancery*. If the plaintiff does not attend on the day fixed for the hearing, his bill is *dismissed* with costs. It may be also *dismissed* for want of prosecution, which is in the nature of a *non-suit* at law; if he suffers three terms to elapse without moving forward in the cause.

DISMOUNTING, in the *Military Art*, the act of unhorsing. Thus, to *dismount* the cavalry, the dragoons, or the like, is to make them alight.

To **DISMOUNT the carriage**, is to break their carriages, wheels, and axle-trees, so as to render them unfit for service. Horses are also *dismounted* when they are rendered unfit for service.

DISORDERLY Horses. See *NUSANCE*.

DISORDERLY Persons. See *VAGABONDS*.

DISORIENTATED, from *dis*, and *orient*, *east*, a term applied to a thing that is turned, or removed from the east, to which it was originally directed.

But the word is most frequently used in a figurative sense, for the disconcerting, or putting a man out of his way or element. Speak of law to a physician, or of physic to a lawyer, and they will both be *disorientated*.

Andrew Marvel uses the word *disorientated*, instead of *disorientated*: Geneva had *disorientated* our geographer.

DISPARAGEMENT, in *Law*, is used for the matching an heir, &c. in marriage, below his or her degree or condition; or against the rules of decency. The word is a compound of the privative particle *dis*, and *par*, *equal*.

DISPART, in *Gunnery*, is used for setting a mark on the muzzle-ring of a piece of ordnance so that a sight-line taken upon the top of the base ring against the touch-hole, by the mark set on or near the muzzle, may be parallel to the axis of the concave cylinder. The common way of doing which, is, to take the two diameters of the base ring, and of the place where the *dispart* is to stand, and divide the difference between them into two equal parts, one of which will be the length of the *dispart*, which is set on the gun with wax or pitch, or fastened there with a piece of twine or marlin; but an instrument may be made to do it to all possible nicety. See *Line of Direction*.

DISPART Frontlet. See *FRONTLET*.

VOL. II. N^o 99.

DISPATCH, a letter on some affair of state, or other business of importance, sent with care and expedition, by a courier express.

The business of *dispatches* lies on the secretaries of state, and their clerks. The king gives directions to his ministers abroad by *dispatches*.

The word is also used for the packet, or mail, containing such letters.

The French, during the reign of Lewis XIV. had a *conseil des dispatches*, council of *dispatches*, held in the king's presence, at which the dauphin, the duke of Orleans, the chancellor, and four secretaries of state, assisted.

DISPAUPER. When any person, by reason of his poverty, is admitted to sue in *EXCEMA pauperis*; if afterwards, before the suit be ended, the same party have any land or personal estate fall to him, or that the court, wherein his suit is depending, think fit for that, or some other reason, to take away the privilege from him, he is then said to be *dispaupered*.

DISPENSARY, or **DISPENSATORY**, a name given to divers collections of recipes for compound medicines, wherein are specified the ingredients, proportions, and circumstances, of the preparation and mixture; the same with what we otherwise call a *pharmacopoeia*, or *antidotaire*. Such are the *Dispensaries* of Meuse, Cordus, that of the College of Physicians at London, and Edinburgh, Quincy, &c.

The apothecaries, in and about London, are obliged to make up their compound medicines according to the formulas prescribed in the College *Dispensary*, and are enjoined to keep always ready in their shops, all the medicines therein enumerated.

DISPENSARY is likewise used for a magazine or office of medicines, kept ready to be *dispensed* at the prime cost of the ingredients, for the benefit of the sick poor.

Of which kind we have had two or three in London, maintained by the college of physicians; one at the college itself, first begun in the year 1663; another in St. Peter's alley, Cornhill; and a third near Covent-garden: where the best medicines were sold for their intrinsic value, and patients were advised every day, but Sunday, at one of the three places. There are at this time several supported by voluntary contribution.

DISPENSATION, in *Law*, &c. a permission to do something contrary to the standing laws; or a relaxation, or suspension of a law, on some just occasion.

Some confound *dispensation* with equity; but they are very different things; for equity is only the correction, or modification, of a law which is too general; but a *dispensation* suspends the obligation of the law itself, and can, therefore, be only given by the legislative power.

The king of France grants *dispensation* of age to some nobility, to be admitted before the legal age; but the greatest dealer in *dispensations* is the pope, who claims the office, *jura divina*, and extends it to every thing: indeed, the more sober of the Romanists themselves deny, that he can give a *dispensation* for a thing contrary either to the divine law, or the law of nature; and confine him to what is contrary to positive laws, as to things relating to fairs, marriages, holding several benefices, &c. And even in these things they set bounds; thus, say they, a *dispensation* in the first degree of affinity, as that of father and daughter, brother and sister, would be abusive and null. But it is certain the pope does not apprehend itself under any such severe restrictions.

The right of giving *dispensation*: they thus prove. It is certain the church has power to make laws: a power which the apostles themselves exercised, and which their successors have continued to exercise after them. Whoever can make a law, can annul it; and much more, can he dispense with it in certain cases: the church, then, may dispense with the laws itself has made, and we find it to have done accordingly in all ages. See *PREMUNIRE*.

The archbishop of Canterbury has a power, by stat. 25 Henry VIII. c. 21. of *dispensing* in any case, within the realm, wherein *dispensation*, not contrary to the law of God, were formerly granted by the see of Rome, as well to the king as to his subjects: but in extraordinary matters, or in a case that is new, the king and council are to be consulted; and the *dispensation* must be confirmed under the broad seal: and during the vacancy of the archbishop's see, the guardian of the spiritualities may grant *dispensation*. Every bishop, of common right, has the power of *dispensing* in common cases.

DISPENSATIONS for parsonage. See *CHAPELAIN* and *PLURALITY*.

DISPENSATION of the king, makes a thing prohibited lawful to be done by the person that has it, though a thing evil in itself will not admit of a *dispensation*. When an offence wrongs none but the king, or if the suit is only the king's for the breach of a penal law, that is not to the damage

of a third person, the king may *dispenſe*: but in caſe the ſuit is the king's, for the benefit of another, he cannot. It was formerly held that the king might in many caſes *diſpenſe* with penal ſtatutes, and the exerciſe of this *diſpenſing* power was one of the moſt ignominious badges of ſlavery and engines of tyranny, which ever diſgraced and haraſſed this country; but by 1 W. and M. ſtat. 2. c. 2. it is declared, that the ſuſpending or *diſpenſing* with laws by regal authority, without the conſent of parliament, is illegal: it is alſo a maxim in law, that it requires the ſame ſtrength to diſſolve, as to create an obligation. See Blackk. Com. vol. 1. p. 142, 185, 342. and vol. 2. p. 429, 432. See **PREROGATIVE**.

DISPENSATION *by ſynonymy*. See **NON-ESTANTE**.

DISPENSATION, in *Pharmacy*, the diſpoſition and arrangement of ſeveral medicines, either ſimple or compound, all weighed in their proper doſes, or quantities; in order to be employed in the making of a compoſition.

DISPERSION, in *Opticks*. *Point of DISPERSION*, is a point from which refracted rays begin to diverge, when their refraction renders them divergent.

It is called *point of diſperſion*, in oppoſition to the point of *converſe*, which is the point wherein converging rays concur after refraction.

But the latter is more uſually called *Junct*, and the former, *virtual focus*.

DISPERSION of Light, occaſioned by the REFRACTIBILITY of the rays, or the nature of the refracting MEDIUM. See **ABERRATION**, and **INFLECTION**.

DISPERSION of Mankind, in the *Hiſtory of the World*, was occaſioned by the CONVERSION of *tanais*, and took place in conſequence of the overthrow of Babel at the birth of Peleg; whence he derived his name: and it appears by the account given of his anceſſors, Gen. chap. xi. 10—16, to have happened in the tenth year after the flood, according to the Hebrew chronology, and by the Samaritan computation in the 421ſt. However, various difficulties have been ſuggeſted by chronologers concerning the true age of this event. Sir John Marſham and others, in order to reconcile the Hebrew and Egyptian chronologies, maintain a *diſperſion* of mankind before the birth of Peleg; others, unable to find numbers ſufficient for the plantation of colonies in the ſpace of 101 years, according to the Hebrew computation, fix the *diſperſion* towards the end of Peleg's life, thus following the computation of the Jews: Petavius aſſigns the 153d year after the flood; Cumberland, the 180th; and Uſher, though he generally refers it to the time of Peleg's birth, in one place aſſigns the 138d after the flood for this event. Mr. Shuckford ſuppoſes the *diſperſion* to have been gradual, and to have commenced with the ſeparation of ſome companies at the birth of Peleg, and to have been completed thirty-one years after. According to the calculation of Petavius, the number of inhabitants on the earth at the birth of Peleg amounted to 32,768; Cumberland makes them 30,000; Mr. Mede ſtates them at 7000 men, beſides women and children; and Mr. Whifton, who ſuppoſes that mankind now double themſelves in four hundred years, and that they doubled themſelves between the deluge and the time of David in fifty years at a medium, when their lives were fix or ſeven times as long as they have been ſince, by his computation, produces about 2389, a number much too inconfiderable for the purpoſes of ſeparating and forming diſtinct nations. This difficulty induced Mr. Whifton to reject the Hebrew, and to adopt the Samaritan chronology, as many others have done; which, by allowing an interval of 401 years between the flood and the birth of Peleg, furniſhes, by the laſt mentioned mode of computation, more than 240,000 perſons. Marſh. Can. Chron. ſec. 1. Petav. Doctrin. Temp. lib. ix. c. 14. Cumb. Orig. Gent. Antiq. p. 142—154. Uſher ad A. M. 1757 & 1787. Whifton's View Chron. O. T. As to the manner of the *diſperſion* of the poſterity of Noah from the plain of Shinar, it was undoubtedly conducted with the utmoſt regularity and order. The ſacred hiſtorian informs us, that they were divided in their lands, every one according to his tongue, according to his family, and according to his nation; Gen. x. 5, 20, 31; and thus, as Mr. Mede obſerves, they were ranged according to their nations, and every nation was ranged by their families, ſo that each nation had a ſeparate lot and each family in every nation. The following abſtract will ſerve to give a general idea of their reſpective ſettlements: Japhet, Noah's eldeſt ſon, had ſeven ſons, viz. Gomer, whoſe deſcendants inhabited thoſe parts of Aſia, which lie upon the Euxine ſea and Hellespont northward, containing Phrygia, Pontus, Bithynia, and a great part of Galatia; the Gallaſians, according to Joſephus, were called Gomeriſ; and the Cimmeri, according to Herodotus, occupied this tract of country; and from theſe Gomeriſs, Cimmeri or Celsi, Mr. Camden de-

rives our ancient Britons, who ſtill retain the name Cymro or Cynru; Magog, the ſecond ſon of Japhet, was probably the father of the Scythians on the eaſt and north-eaſt of the Euxine ſea; Madai planted Media, though Mr. Mede aſſigns Macedonia to his ſhare; Javan was the father of the Grecians about Ionia, whoſe country lies along upon the Mediterranean ſea; the radicals of Javan and Ionia being the ſame 21; Tubal and Meſhech belonged Cappadocia and the country which lies on the borders of the Euxine ſea; and from them, migrating over the Caucasus, it is ſuppoſed the Ruſſians and Muſcovites are deſcended; and Thim occupied Thrace. The ſons of Shem were five: Elam, whoſe country lay between the Medes and Meſopotamians, and was called by the Gentile writers Elymais; and Joſephus calls the Elamites the founders of the Perſians; Aſhur, who was driven out of Shinar by Nimrod, afterwards ſettled in Aſſyria, and there built Nineveh and other cities; Arphaxad, who gave name to the country which Ptolemy calls Arraphacina, a province of Aſſyria, though Joſephus makes him the father of the Chaldees; Lud, who inhabited and gave name to the country of Lydia about the river Maender, remarkable for its windings, in Asia Minor; and Aram, the father of the Aſſyrians. Ham, the youngſt ſon of Noah, had four ſons, viz. Cuſh, whoſe poſterity ſpread into the ſeveral parts of Arabia, over the borders of the land of Elom, into Arabia Felix, up to Midian and Egypt; Mizraim, the father of them who inhabited Egypt and other parts of Africa; Phut, to whom Bochart aſſigns the remaining part of Africa, from the lake Trimides to the Atlantic ocean, called Lybia; and Canaan, to whom belonged the land of Canaan, whence the Phoenicians derived their origin. Mede's Works, vol. 1. diſc. 50. p. 276, &c. Bochart, Phaleg. lib. iii. & iv. Patrick in loc. Shuckford's Conn. vol. 1. book 1. and Un. Hiſt. vol. 1. part 3. book 1. chap. 2. § 6.

Dr. Bryant has advanced a new hypotheſis on this ſubject, and ſupported it with his uſual acuteness and learning: he maintains, that the *diſperſion* as well as the CONVERSION of *tanais* was local, and limited to the inhabitants of the province of Babel; that the ſeparation and diſtribution recorded to have taken place in the days of Peleg, Gen. x. 25, 31, 32, which was the reſult of divine appointment, occaſioned a general migration; and that all the families among the ſons of Noah were concerned in it: the houſe of Shem, from whom Meſſiah was to ſpring, was particularly reſpectful in this diſtribution; the portion of his children was near the place of ſeparation; they in general had Aſia to their lot; as Japhet had Europe, and Ham the large continent of Africa. But the ſons of Cuſh would not ſubmit to the divine diſpenſation; they went off under the conduct of Nimrod, and ſeem to have been for a long time in a roving ſtate: however, at laſt they arrived at the plains of Shinar, and having ejected Aſhur and his ſons, who were placed there by divine appointment, ſeized his dominions, and laid there the foundation of a great monarchy. But afterwards fearing left they ſhould be divided and ſcattered abroad, they built the tower of Babel, as a land-mark, to which they might repair, and probably to answer the purpoſes of an idolatrous temple, or high altar, dedicated to the hoſt of heaven, from which they were never long to be abſent. They only, viz. the ſons of Cuſh or the Cubites, and their aſcendents from other families, who had been guilty of rebellion againſt divine authority, and of wicked ambition and tyranny, were puniſhed with the judgment of confounded ſpeech through a failure in ſilial utterance, and of the *diſperſion* recorded in Gen. x. 8, 9; in conſequence of which they were ſcattered abroad from this city and tower, without any certain place of deſtination. The Cubites invaded Egypt or the land of Mizraim, in its infant ſtate, ſeized the whole country, and held it for ſome ages in ſubjection; and they extended likewiſe to the Indies and Guagee, and ſtill farther into China and Japan. From them the province of Cuſhan or Cuſhen in Egypt derived its name; here they obtained the appellation of royal ſhepherds; and when they were by force driven out of the country, after having been in poſſeſſion of it for two hundred and ſixty or two hundred and eighty years; the land which they had been obliſed to quit was given to the Iſraelites, who were alſo denominated ſhepherds; they ſhould not be confounded with the former or the antecedent inhabitants of Goffien. Bryant's Analyſis of Ancient Mythol. vol. iii. p. 16, &c.

DISPERSION of inflammation, in *Medicine*. See **INFLAMMATIONS**.

DISPLANTING, among *Gardeners*, is the plucking up a tree or plant out of the ground.

DISPLANTING ſcop, an inſtrument for taking up plants with earth about their roots.

DISPLAYED,

DISPLAYED, in *Heraldry*, is understood of the position of an eagle, or other bird, when it is erect, with its wings expanded, or spread forth.

DISPONDEE, in the *Greek* and *Latin Poetry*, a double spondee, or a foot consisting of four long syllables: as *judicium, elatante, Jovis, Caesar*.

DISPOSITION, from *dis*, and *pono*, I place, in *Architecture*, is the just placing of all the several parts of an edifice, according to their proper nature and office. See **BUILDING**.

DISPOSITION, in *Logic*, is that operation of the mind, whereby we put the ideas, propositions, and arguments which we have formed concerning one subject, into such an order as is fittest to gain the clearest knowledge of it, to retain it longest, and to explain it to others in the best manner: the effect of this is called **METHOD**. Watts's *Logic*.

DISPOSITION, in a *Military Style*, is the arrangement of an army or body of men upon the most advantageous ground, and in the best situation for a vigorous attack or defence.

DISPOSITION, in *Rhetoric*, is defined, by Cicero, the act of disposing the things, or arguments, invented or found out, into a proper order; or a due placing, or ranging, the several parts of speech, or discourse.

The *disposition* makes one of the great branches, or divisions, of rhetoric. Horace was the first among the Greeks, that made them sensible of the beauty of *disposition*; and Cicero among the Romans.

The *disposition* is of the same necessity in oratory, as the marshalling of an army in order to a battle; or a beautiful composition in architecture, painting, &c. Horace enjoins it expressly in poetry: *Singula quæque locum in nostro versu habent*. The *disposition*, then, is the order, or arrangement, of the parts of an oration; which parts are usually reckoned four, viz. the *exordium*, or *beginning*; the *narratio*, or *confirmation*; and the *peroration*, or *conclusion*. Though some make them fix, viz. the *exordium*, *dispositio*, *narratio*, *confirmatio*, *confutatio*, and *peroratio*; as indicated in this popular verse:

Exorsus, narratio, facti, firmi, refutatio, peroratio.

But the *dispositio* is more naturally referred to the *exordium*; and the *confirmatio* to the *confirmatio*.

The *dispositio* is either *natural* or *artificial*. *Natural*, is the order the parts are above rehearsed in. *Artificial*, is when, for some particular reason, we recede from the order of nature. See each part under its proper article, **EXORDIUM**, &c.

DISPROPORTION, a term of relation implying a want of proportion, or symmetry.

DISPROVING, in *Rhetoric*. See **REFUTATION**.

DISPUTE, or **DISPUTATION**, from *dis*, and *suta*, I think, in the *Schools*, &c. a contest, or combat, either by word or writing, on some point of learning or religion, for a degree, prize, exercise, or even for the mere sake of truth, or advantage of a party, or the honour of a triumph. See **THESES**.

The *Port Royalists* take occasion to observe, that nothing gives so many different lights and openings, for discovering the truth, as *disputation*. The movement of a mind, employed fully in the examination of any subject, are usually too cool and languid; the mind needs a certain degree of heat to awake its ideas. Now, by the oppositions in a *dispute*, we come to find wherein the difficulty lies, and the vigour the mind has acquired enables us to surmount it.

DISQUISITION, from *dis*, and *quæro*, I enquire, an enquiry into the nature, kinds, and circumstances of any problem, question, or topics in order to gain a right notion of it, and to discourse clearly about it.

DISSECTION, from *dis*, and *secô*, I cut, in *Anatomy*, the operation of cutting and dividing the parts of an animal body, with a knife, scissors, &c. in order to see and consider each of them apart.

The ancients made *dissections* of living men: as we read of Herophilus and Erasistratus; and, in our own times, of Corpus and Vesalius.

Yet, Le Genèrè observes, that the *dissection* of a human body, even dead, was held a sacrilege till the time of Francis I. And the same author assures us, he has seen a consultation held by the divines of Salamanca, at the request of Charles V. to settle the question, whether or no it were lawful, in point of conscience, to *dissect* a human body, in order to learn its structure? See **ANATOMY**.

DISSEISIN, in *Law*, an unlawful dispossessing a man of his land, tenement, or other innalienable and incorporeal right.

Disseisin is of three sorts; viz. *single disseisin*, committed by force, without force and arms; and *disseisin by force*, for which see **DROVING**; and *fresh disseisin*. See

also **RE-DISSEISIN** and **POST-DISSEISIN**. *Wrongful force* makes no defect in law.

Assises are called writs of *disseisin*, which lie against disseisors in any case: whereof some are termed *little writs* of *disseisin*, as being vicinial, that is, liable before the sheriff in the county-court, because determinable by him without assise.

DISSEISOR, he who *disseiseth*, or puts another out of his land: as *disseisor* is he who is portus.

If a *disseisor*, after he has expelled the right owner, gains peaceable possession of the lands five years without claim, and continues in possession, so as to die seised, and the land descends to his heirs, they will have a right to the possession till the owner recovers at law; and the owner shall lose his estate for ever, if he doth not prosecute his suit within the time limited by the Statute of limitations.

DISSEMINATE vocatur. See **VACUUM disseminatum**.

DISSENSERS, a general denomination of equal import with non-conformists.

It expresses certain sects, or parties, in England, who, in matters of religion, church-discipline, and ceremonies, dissent from, or disagree with the church of England, and have a toleration by law for the same. Such, particularly, are the presbyterians, independents, anabaptists, and quakers. See **PREBAPTISTANS**, &c.

At the Revolution, a law was enacted, that the Statute of queen Elizabeth, and king James I. concerning the discipline of the church, should not extend to protestant dissenters: but the persons dissenting are to subscribe the declaration of 30 Car. II. c. 1, and take the oaths of the declaration of fidelity, &c. And they must not hold their meetings until their place of worship is certified to the bishop, &c. or to the justices at their quarter sessions, and regulated there; also they are not to keep the doors of their meeting-houses locked, &c. If any person disturbs them at their worship, on conviction at the sessions, he shall forfeit 20*l.* Stat. 1 W. and M. And there are many statutes relating to dissenters before the toleration act: as 5 and 6 Edw. VI. c. 1. 23 Eliz. c. 1. 3 Jac. I. c. 4. 13 Car. II. c. 1. 17 Car. II. c. 22 Car. II. c. 1. 1 W. and M. c. 18. 10 Anne, c. 2. 1 Geo. I. c. 6. &c.

DISSEPIPIENTUM, among *Banians*, the thin septum separating the cells of the fruit of plants.

DISSIDENTS, a denomination applied in Poland to those of the Lutheran, Calvinistic, and Greek profession. The king of Poland engages by the *pacta conventa* to tolerate them in the free exercise of their religion, but they have often had reason to complain of the violation of these piousness.

DISSIMILAR leaves, denote the two first leaves of any plant as its first shooting out of the ground. They are thus called, because they usually are of a different form from the common leaves of a grown plant. These Dr. Grew observes to be nothing but the very lobes of the seed thus expanded, and thus advanced.

Their use is for the protection of the plumes, which being young and tender, is thus guarded on each side, and has also some rain and dew gradually conveyed down to it by this means. See **PLUMES**.

DISSIMILAR, in *Anatomy*. Authors divide the parts of the body into *similar*, and *dissimilar*.

Dissimilar parts, by some called *also compound*, and *organo* parts, are such as may be divided into various parts, of different structure, &c. Thus the hand is divisible into veins, muscles, bones, &c. whole subdivisions are neither of the same nature nor denomination.

DISSIMILITUDE, in *Geometry*, &c. See **SIMILITUDE**.

DISSIMILITUDE, or **DISSIMILI**, in *Rhetoric*, &c. an argument, wherein, from *dissimilar*, or unlike things, other *dissimilar* are deduced.

Thus Cicero, *Si barbarorum est in domo vivere, nostra censura sempiternum tempus spectare debet*. Catullus furnishes a very beautiful argument from *dissimilitude*.

*Solæ occideret et redire possunt,
Nobis cum simul occidit brevis lux,
Nec est perpetua una dormienda.*

DISSIMULATION, in *Morals*, the act of dissembling, by fallacious appearances, or false pretensions.

Good princes regard *dissimulation* as a necessary vice; but tyrants consider it as a virtue.

It is apparent that secrecy is often necessary, to oppose those who may be willing to circumvent our lawful intentions. But the necessity of precaution would become very rare, were no enterprizes to be formed, but such as could be avowed openly. The frankness with which we could then act, would engage people in our interests. Marthal Biron would have saved his life, by dealing ingenuously with Henry IV.

With respect to *dissimulation*, three things are to be observed; 1. That the characters of those are not to be elicited,

effected, who are referred and cautions without distinction. 2. Not to make secrets of unimportant matters. 3. To conduct ourselves in such manner, as to have as few secrets as possible.

DISSIPATION, in *Physics*, an insensible loss, or consumption, of the minute parts of a body: or, more properly, that flux whereby they fly off, and are lost. See *EFFLUVIA*.

We do not say *dissipation*, but loss of blood, in speaking of the blood discharged at a wound, or in any other sensible manner: on the contrary, we say *dissipation*, or expence, of spirits: this is more copious than that of the solid parts; and consequently, the reparation ought to be more copious.

DISSIPATION, *Circle of*, or *ABERRATION*, in *Optics*, denotes that circular space upon the retina of the eye, which is occupied by the rays of each pencil in indistinct vision: thus, if the distance of the object, or the constitution of the eye be such, that the image falls beyond the retina, as when objects are too near; or before the retina, when the rays have not a sufficient divergency, the rays of a pencil, instead of being collected into a central point, will be *dissipated* over this circular space: and all other circumstances being alike, this circle will be greater or less, according to the greater or lesser distances from the retina of the foci of refracted rays. But this circle causes no perceptible difference in the distinctness of vision, while that circle is not greater than some determinate magnitude; as soon as it exceeds that magnitude, we begin to perceive an indistinctness, which increases as the circle of *dissipation* increases, and at length the object is lost in confusion. This circle is also greater or less, according to the greater or less magnitude of the visible object; and though it is not easy to assign the diameter of the said circle, it seems very probable, that vision continues distinct for all such distances, or so long, as these circles, or the pencils of light from them do not touch one another upon the retina; and the indistinctness begins, when the said circles begin to interfere. It has been often observed, that a precise union of the respective rays upon the retina is not necessary to distinct vision; but the first author that ascertained the fact beyond all doubt, was Dr. Jurin. See a variety of observations and experiments on this subject, in his *Essay on Distinct and Indistinct Vision*, in *Smith's Optics*, Appendix. See *MOONS*, and *VISION*.

DISSIPATION, *Radius of*, is the radius of the circle of *DISSIPATION*.

DISSOLVENT, something that *dissolves*, i. e. divides, and reduces a body into its smallest parts. See *DISSOLUTION*.

Thus, *AQUA REGIA* is the *dissolvent* of gold; *AQUA FORTIS* of silver, and other metals; water, of salts and gums; spirit of wine, of resins; spirit of vinegar, of pearls, corals, &c.

Sea-salt is found the proper *dissolvent* of gold. This, in almost any form, whether as a fluid, or a solid, or a spirit, does the business: accordingly, this is a basis, or fundamental ingredient, of *aqua regia*.

So nitre is the proper *dissolvent* of silver, and has that effect, in whatever form it is applied: and, accordingly, it is the basis of *aqua fortis*.

Spirit of nitre, added to that of sea-salt, makes it *dissolve* gold the better: but spirit of sea-salt, added to spirit of nitre, disables it from having any effect on silver. Yet Mr. Homberg furnishes an instance of a *dissolution* of silver made by the *dissolvent* of gold. An *aqua regia* may be composed of spirit of salt, and spirit of nitre, only in such small quantity each, that they may float separately in a third liquor, and not meet often enough to unite, at least not in any quantity. This water may be made so weak as not to *dissolve* gold, but only extract a slight yellow tincture from it, that scarce takes off any thing of the weight of the metal: nor will it *dissolve* silver, as being too weak; so that both metals are safe from it. But this *aqua regia*, after it has *dissolved* gold as far as it can do: that is, after it has extracted a yellowish tincture from it, is still in a condition to *dissolve* silver.

This phenomenon Mr. Homberg accounts for hence: that spirit of salt, whether alone, or joined with spirit of nitre, being employed in keeping those few particles of gold *dissolved*, will not meddle with the silver: which, by this means, receiving the impression of the greater quantity of spirit of nitre alone, is *dissolved* thereby. But the experiment cannot be inverted, i. e. *aqua regia* cannot begin with *dissolving* silver lightly first, and afterwards *dissolve* gold, because spirit of nitre does not hinder spirit of salt from acting on gold, as spirit of salt does spirit of nitre from acting on silver.

Dissolvents are usually called by the chemists, *menstruums*. **DISSOLVENT**, *Universal*. See *ALCAHEMIST*.

DISSOLUTION, in *Chemistry*, *Pharmacy*, and *Physics*, a

dissolution, or analysis, of the structure of a mixed body: whereby, what was one, and contiguous, is divided into little parts, either homogeneous, or heterogeneous. See *ANALYSIS*, and *DIVISION*.

Dissolution, then, is a general name for all reductions of concrete bodies into their smallest parts, without any regard either to solidity or fluidity: though, in the usual acceptance of the word among authors, it is restrained to the reduction of solid bodies into a state of fluidity, by the action of some fluid *menstruum* or *dissolvent*, in which case an union is formed between the integrant parts of one body, and those of another of a different nature; so that it is nothing else than an act of COMBINATION: this is more properly expressed by *SOLUTION*, as a branch of *dissolution*.

According to the opinion of F. Tertius de Lanis, adopted by the learned Boerhaave, in his *Chemistry*, the power, or faculty, of dissolving, is lodged in fire alone.

Other fluids, commonly supposed dissolvents, only produce their effect by means of the fiery spicula they abound with. Even air, which is judged a powerful *menstruum*, owes all its force to the rays of light diffused therein.

Sir Isaac Newton accounts for all *dissolution*, and the several phenomena thereof from the great principle of attraction; and, in effect, the phenomena of *dissolution* furnish a great part of the arguments and considerations, whereby he proves the reality of that principle.

A specimen of that great author's way of philosophizing on the subject of *dissolution*, takes us follows:

When salt of tartar dissolves by lying in a moist place, is not this done by an attraction between the particles of the salt of tartar, and those of the water which float in the air in form of vapours? And why does not common salt, or salpêtre, or vitriol, do the like, but for want of such an attraction? And when *aqua fortis*, or spirit of vitriol, poured on steel filings, dissolves the filings, with a great heat and ebullition, is not this heat and ebullition effected by a violent motion of the parts? And does not that motion argue, that the acid parts of the liquor rush towards the parts of the metal with violence, and run forcibly into its pores; till getting between the outermost particles and the main mass of metal, they loose them therefrom, and let them at liberty to float off into the water? When a solution of iron, in *aqua fortis*, dissolves lapis calaminaris, and lets go the iron; or a solution of copper dissolves iron immersed in it, and lets go the copper; or a solution of mercury in *aqua fortis*, poured on iron, copper, tin, or lead, dissolves the metal, and lets go the mercury; does not this argue, that the acid particles of the *aqua fortis* are attracted more strongly by the lapis calaminaris, than by iron; by iron, than by copper; by copper, than by silver; and by iron, copper, tin, and lead, than by mercury? And is it not for the same reason, that iron requires more *aqua fortis* to dissolve it, than copper; and copper, more than the other metals; and that of all metals, iron is dissolved most easily, and is most apt to rust; and next after iron, copper? When *aqua fortis* dissolves silver, and not gold; and *aqua regia* dissolves gold, and not silver; may it not be said, that *aqua fortis* is subtle enough to penetrate the pores of gold as well as of silver, but it wants the attractive force to give it entrance; and the same of *aqua regia*, and silver? And when metals are dissolved in acid *menstruums*, and the acids, in conjunction with the metal, act after a different manner; so as that the taste of the compound is milder than that of the simples, and sometimes a sweet one; is it not because the acids adhere to the metallic particles, and thereby lose much of their activity? And if the acid be in too small a proportion to make the compound dissolvable in water; will it not, by adhering strongly to the metal, become unactive, and lose its taste; and the compound become a tasteless earth? For such things as are not dissolvable by the moisture of the tongue are insipid. Newt. Opt. in Calc.

Dr. Friend gives us a mechanical account of *dissolution*, in the instance of salt dissolved in water; which is the most simple operation that falls under this head. This motion he ascribes to that attractive force, which is so very extensive in natural philosophy, that there is no kind of matter but what is under its influence. It may be observed, he says, that the corpuscles of salts, which are the most simple of any, are wital very minute, and, for their bulk, very solid; and therefore they exert a very strong attractive force, which, *ceteris paribus*, is proportional to the quantity of matter. Hence it comes to pass, that the particles of water are more strongly attracted by the saline particles than they are by one another: the particles of water, therefore, cohering but loosely, and being easily movable, approach the corpuscles of salts, and run, as it were, into their embraces; and the motion of them is quicker, or slower, according

to their less or greater distances; the attractive force, in all bodies, being strongest at the point of contact. Therefore, if salt be thrown into the middle of a dish full of water, we shall find the aqueous particles, which are in the middle of the dish, sharp and pungent to the taste; but the water upon the sides of the vessel almost insipid: so that, when such a motion once arises, the aqueous particles are carried with the same force toward the salts; and the moment of them is to be estimated from the ratio of their weight, and celerity conjointly. By the force of this impulse, they open to themselves a passage into the pores of the salts, which are very numerous; and, at length, they so break and divide its texture, that all cohesion of the parts is destroyed: hereupon, being separated and removed to a convenient distance from one another, they are dispersed, and float here and there about the water.

Mr. Geoffroy furnishes some curious experiments on cold dissolution: it is nothing surprising, that a simple dissolution should be cold; that common water, for instance, wherein sea-salt, or sal ammoniac, or vitriol, has been cast, should become colder by the mixture of such salts; it being obvious, that the salts, being of themselves destitute of motion, and coming to share that which the fluidity gives the water, must diminish it, when they become intimately mixed therewith by dissolution; and it is generally agreed, among philosophers, that heat is a motion, and cold a cessation, or, at least, a diminution of motion.

Yes, notwithstanding this general principle, it is no great wonder all dissolutions are not cold, as those are of all volatile alkalis in common water; but that some are hot, as those of all fixed alkalis. This difference may be accounted for hence, that all fixed alkalis having been calcined by a vehement fire, they have impudently retained in the pores some of the particles thereof. But it is surprising, that dissolutions, accompanied with fermentation, &c. where the matters boil and swell, and that with a great noise, should be cold, and make the thermometer fall, when immersed therein.

This coldness, with so considerable an augmentation of motion, is somewhat extraordinary. But this is not all; for of these cold fermentations, there are some that emit hot vapour. Thus it is with a mixture of oil of vitriol, and sal ammoniac; for a thermometer being plunged in the mixture, and another a little higher to receive only the fumes thereof, the first thermometer is seen to fall very hastily, through the coldness of the fermentation; and the latter to rise, through the heat of the vapours. Mr. Geoffroy adds an experiment, showing that cold water is rendered still colder, for a few moments, by throwing a large quantity of live coals therein.

Dissolution of metals, &c. by fire, is particularly called *fusio*.

Dissolution of the blood, is an affection of that humour, directly opposite to coagulation.

The *dissolution* is such a comminution of the fibrous parts of the blood, as indicates for it that separation of the crassamentum from the serous part, which always exists in healthy blood, on its cooling out of the body.

This *dissolution* is frequently the consequence of malignant and pestilential fevers, and shows itself in petechiae, or purple spots; also of certain poisons, particularly the bites of venomous beasts, &c.

Dissolution of parliament. See PARLIAMENT.

DISSONANCE, or **DISCORD**, in *Music*, a false consonance, or concord.

A *distance* is properly the result of a mixture, or meeting, of two sounds, which are disagreeable to the ear: such are *ditone*, *tritone*, *sexta fissa*, *redundans*, *quarta*, *sexta*, &c.

Dissonances are sometimes used in music, and have a good effect therein, though it be only occasionally. See DISCORD.

DISSYLLABLE, a word of two syllables; as *fortune*, *lament*, &c.

The *pondeus*, *trocheus*, *iambus*, and *pyrrhichius*, are *dissyllable* feet. See SPONDEE, &c.

DI-STAFF, an instrument about which flax is tied, in order to the spinning of it.

DI-STAST, *stipite*, a name sometimes given to the *attractibility* of authors. See THISTLE.

DISTANCE, properly denotes the shortest line between two points, objects, &c.

Distance, according to an ingenious author, cannot of itself and immediately be seen. For *distance* being a line directed endwise to the eye, it projects only one point in the fund of the eye, which point remains invariably the same, whether the distance be longer or shorter. Dr. Berkeley, Essay on Vision.

A late eminent mathematician observes, that the *distance*

here spoken of is *distance* from the eyes; and that what is said of it must not be applied to *distance* in general. The apparent *distance* of two stars is capable of the same variations as any other quantity or magnitude. Visible magnitudes consist of parts into which they may be resolved, as well as tangible magnitudes; and the proportions of the former may be assigned, as well as those of the latter: so that it is going too far to tell us, that visible magnitudes are no more to be accounted the object of geometry than words, and that the ideas of space, and things placed at a *distance*, are not, strictly speaking, the object of sight, and are not otherwise perceived by the eye than by the ear. Mr. Maclaurin, in his account of Sir Isaac Newton's Discoveries, p. 225. The word is also used figuratively for an interval, not only in respect of place, but also of time, or quality. Thus, we say the *distance* of the creation of the world, from the nativity of Jesus Christ, is upwards of four thousand years: the *distance* between the Creator and creature is infinite.

For the division of DISTANCES, or the manner wherein we come by the idea of *distance* in objects, see VISIBLE.

DISTANCE, in *Astronomy*. The *distance* of the sun, planets, and comets, is found from their PARALLAX.

The proportional or relative *distances* of the planets are deduced with great exactness from the theory of gravity: for Kepler has long since discovered that the squares of their periodical times are as the cubes of their *distances*. Epit. Astron. lib. iv. See also Greg. Astr. book i. prop. 40. If we, therefore, suppose the mean *distance* of the earth from the sun to be 100000, we shall obtain by the preceding analogy, from the periodical times which are known, the relative *distances* of the other planets: thus,

The periodical revolutions to the same fixed star in days and decimal parts of a day.

Mercury. Venus. Earth. Mars. Jupiter. Saturn.

87.9692 224.6176 365.2564 686.9782 4332.11410759.275

Relative mean *distances* from the Sun.

38710 72333 100000 152369 520096 954006

In order to find the real *distance* of the earth, and for an account of the real *distances* of the other planets, see PARALLAX and PLANETS.

For the *distances* of the secondary planets from the centres of their respective primaries, see SATELLITES.

That of the fixed stars, as having no sensible parallax, we can do little more than guess at.

Dr. Hooke, by exact observation with a telescope of sixteen feet, perpendicularly placed, first discovered, that the *distances* of the stars from the zenith is not the same at all times of the year: particularly the bright star in the Dragon's Head he found twenty-seven or thirty seconds nearer the zenith of Greenwich college, in the winter solstice, than the summer; and, after him, Mr. Flamsteed observed the like variations in the pole-star. See LIGHT.

DISTANCE of the sun from the moon's node, or apogee, is an arch of the ecliptic intercepted between the sun's true place, and the moon's node, or apogee. See NODE.

DISTANCE, Cartae. See CARTAE.

DISTANCE of the hostiles, in Fortification, is the side of the exterior polygon.

DISTANCES, in Geometry, are measured by the chain, demipedala, and the like. See CHAIN, &c.

DISTANCES, Inexactiles, are found by taking bearings thereto from the two extremes of a line, whose length is given. See PLAIN-TABLE, THEODOLITE, &c.

DISTANCE, in Geography, is the arch of a great circle intersected between two places.

To find the *distance* of two places A and B (Tab. Geogr. fig. 4.), far remote from each other. Assume two stations, C and D, from which both the places A and B may be seen; and with a proper instrument find the angles ADC, CDB, ACD, and DCB; and measure the *distance* CD.

Then in the triangle ACD we have two angles given, ACD and ADC, together with a side; from which, by an easy rule in trigonometry, delivered under the article TRIANGLE, we find AD.

So also, in the triangle CDB, the base DC, and the angles at the same, being given; DB is found.

Lastly, in the triangle ADB, having the sides AD and DB, together with the included angle ADB; the *distance* required, AB, is found by the rules given for the resolution of triangles.

The height of a remote object being known, to find its *distance*, when the eye first descends it; and, again, the height of the eye being given, to find the *distance* to which the eye can reach on the surface of the sea, or land. Add the height of the eye AB (fig. 9.) to the

femidiameter of the earth BC, by which you have AC; and since in the reſtangled triangle ADC the ſides AC and DC are given, the angle DCA is found by the common rule for reſolution of triangles, the quantity of which angle forms the arch DB; which arch, converted into feet, or the like, gives the *diſtance* required.

Suppoſe e. g. the height of the eye AB five feet, which is ſomewhat leſs than in a man of ordinary ſtature; ſince BC is 19695539, AC will be 19695544; and the angle DAB will be found $89^{\circ} 57' 43''$; conſequently DCB, or the arch DB, is $2' 17''$, or $137''$; and therefore, ſince $1''$, or $3600''$, make 343752 Paris feet, DB is 130815 feet.

After the ſame manner we find the *diſtance* DB; to which an object of a given altitude AB may be ſeen; and, conſequently, we know what diſtance we are off from an object of a given altitude, when we firſt diſcover the top thereof. See *HORIZON*.

DISTANCE, Apparent, in Optics, that *diſtance* which we judge an object to be from us when ſeen afar off, being commonly very different from the true *diſtance*; becauſe we are apt to think that all very remote objects, whoſe parts cannot well be diſtinguiſhed, and which have no other object in view near them, to be at the ſame *diſtance* from us, though perhaps the one is thouſands of miles nearer than the other, as is the caſe with regard to the ſun and moon.

M. De la Hire enumerates five circumſtances, which aſſiſt us in judging of the *diſtance* of objects; viz. their apparent magnitude, the ſtrength of the colouring, the direction of the two eyes, the parallax of the objects, and the diſtinctneſs of their ſmall parts. Dr. Smith maintains, that we judge of *diſtance* principally, or ſolely, by the apparent magnitude of objects; and concludes univerſally, that the apparent *diſtance* of an object ſeen in a glaſs, is to its apparent *diſtance* ſeen by the naked eye, as the apparent magnitude to the naked eye is to its apparent magnitude in the glaſs: but Alhazen long ſince obſerved, that we do not judge of *diſtance* merely by the angle under which objects are ſeen; and Mr. Robins clearly ſhews the hypotheſis of Dr. Smith to be contrary to fact, in the moſt common and ſimple caſes. Thus, if a double convex glaſs be held upright before ſome luminous object, as a candle, there will be ſeen two images, one erect, and the other inverted: the firſt is made ſimply by reflexion from the neareſt ſurface; the ſecond, by reflexion from the farther ſurface, the rays undergoing a refraction from the firſt ſurface both before and after the reflexion. If this glaſs has not too ſhort a focal *diſtance*, when it is held near the object, the inverted image will appear larger than the other, and alſo nearer; but if the glaſs be carried off from the object, though the eye remain as near to it as before, the inverted image will be diminiſhed to much farther than the others that it will, at length, appear very much leſs than it, but ſtill nearer. Here, ſays Mr. Robins, two images of the ſame object are ſeen under one view, and their apparent *diſtances* immediately compared; and it is evident that thoſe *diſtances* have no neceſſary connexion with the apparent magnitude. This experiment may be made ſtill more convincing, by ſticking a piece of paper on the middle of the lens, and viewing it through a ſhort tube. He obſerves farther, that the apparent magnitude of very diſtant objects, is neither determined by the magnitude of the angle only under which they are ſeen, nor is the exact proportion of that angle compared with their true *diſtance*, but is compounded alſo with a deception concerning the *diſtance*; ſo that if we had no idea of difference in the *diſtance* of objects, each would appear in magnitude proportional to the angle under which it was ſeen; and if our apprehenſion of the *diſtance* was always juſt, our idea of their magnitude would be, in all *diſtances*, unvaried; but in proportion as we err in our conception of their *diſtance*, the greater angle ſuggeſts a greater magnitude. By not attending to this compound effect, Mr. Robins apprehends that Dr. Smith was led into his miſtake.

Montucla alſo, without being apprized of what Mr. Robins had written, made ſimilar objections to the hypotheſis of Dr. Smith. Dr. Porterfield has made ſeveral remarks on the five methods of judging concerning the *diſtance* of objects above recited from M. De la Hire; and he has added to them, the conformation of each eye. See *CIRCLE OF DISSIPATION*. This, he ſays, can be of no uſe to us, with reſpect to objects that are placed without the limits of diſtinct viſion. But the greater or leſs confuſion with which the object appears, as it is more or leſs removed from thoſe limits, will aſſiſt the mind in judging of its *diſtance*: the more confuſed it appears, the farther will it be deemed. However, this confuſion hath its limits; for when an object is placed at a certain

diſtance from the eye, to which the breadth of the pupil bears no ſenſible proportion, the rays proceeding from a point in the object may be conſidered as parallel; in which caſe, the picture on the retina will not be ſenſibly more confuſed, though the object be removed to a much greater *diſtance*. The moſt univerſal, and often the moſt ſure means of judging of the *diſtance* of objects, he ſays, is the angle made by the optic axes; our two eyes are like two different ſtatues, by the *diſtance* of which *diſtances* are taken; and this is the reaſon why thoſe perſons who have loſt the light of one eye, fo frequently miſs their mark in pouring liquor into a glaſs, ſnuffing a candle, and ſuch other actions as require that the *diſtance* be exactly diſtinguiſhed. With reſpect to the method of judging by the apparent magnitude of objects, he obſerves, that this can only ſerve, when we are otherwiſe acquainted with their real magnitude. Thus he accounts for the deception to which we are liable in eſtimating *diſtances*, by an extraordinary magnitudes that terminate them; as, in travelling towards a large city, caſtle, or cathedral, we fancy them to be nearer than they really are. Hence alſo animals and ſmall objects ſeen in a valley, contiguous to large mountains, or on the top of a high mountain or building, appear exceeding ſmall. Dr. Jurin accounts for the laſt recited phenomenon, by obſerving that we have no diſtinct idea of *diſtance* in that oblique direction, and therefore judge of them merely by their pictures on the eye. Dr. Porterfield obſerves, with reſpect to the ſtrength of colouring of different objects, that if we are aſſured they are of a ſimilar colour, and one appears more bright and lively than the other, we judge the brighter object to be the nearer. When the ſmall parts of objects appear confuſed, or do not appear at all, we judge that they are at a great *diſtance*, and *vice verſa*; becauſe the image of any object, or part of an object, diminiſhes as the *diſtance* of it increaſes. Finally, we judge of the *diſtance* of objects by the number of intervening bodies, whereby it is divided into ſeparate and diſtinct parts; and the more this is the caſe, the greater will the *diſtance* appear. Thus, *diſtances* upon uneven ſurfaces appear leſs than upon a plane, becauſe the inequalities do not appear, and the whole apparent *diſtance* is diminiſhed by the parts that do not appear in it: and thus the banks of a river appear contiguous to a diſtant eye, when the river is low and not ſeen. Accidents de la Vue, p. 358. Smith's Optics, vol. i. p. 52. and Rem. p. 51. Robins's Tracts, vol. ii. p. 230, 247, 251. Porterfield on the Eye, vol. i. p. 105, vol. ii. p. 387, &c. See PRIESTLEY'S Hiſt. of Viſion, p. 205; and p. 689, &c. See VISIBLE.

DISTANCE, in Navigation, is the number of miles, or leagues, that a ſhip has ſailed from any point. See *SAILING*.

DISTANCE, Line of, in Perspective, is a right line drawn from the eye to the principal point. Such is the line OF (*Tab. Perspective*, fig. 12.), drawn between the eye O, and the principal point F.

This, as it is perpendicular to the plane, or table, can only be the *diſtance* from the eye to the table.

DISTANCE, Point of, in Perspective, is a point in the horizontal line at ſuch *diſtance* from the principal point, as is that of the eye from the ſame.

Such are the points P and Q (*Tab. Perspective*, fig. 12.) in the horizontal line PQ; whole *diſtance* from the principal point F, is equal to that of the eye from the ſame F.

DISTASTE, or DISCOURT, a loſs of appetite, or an aversion, or repugnance, to foods which are commonly eaten.

Diſtaſte is held, by phyſicians, one of the principal diſorders of the ſtomach. It ariſes from a want of ſenſation in the upper orifice of the ventricle, which may be occaſioned various ways: as by a too great abundance of food; thick, heavy humours in the ſtomach; fat, viſcid aliment; obſtructions of the laſteals; ſuppreſſions of the uſual evacuations; intermiſſions of the ordinary exerciſes, a defect of the nerves, in having their natural faculty aboliſhed, or ſuſpended as in a lethargy, and apoplexy; and according to Syllivius, by a groſs viſcid ſaliva, or a thick bile, aſcending out of the ſmall guts into the ſtomach.

DISTEMPER, in Medicine. See *DISEASE*.

DISTEMPER is alſo uſed in *Painting*, for the working up of colours with ſomething elſe beſides bare water, or oil.

If the colours be prepared with the former of theſe, that kind of painting is called *limning*; and if with oil, it is called *painting in oil*, or ſimply *painting*.

If the colours be mixed with ſize, whites of eggs, or any ſuch proper glutinous, or unctuous ſubſtance, and not with oil, they then ſay, it is done in *diſtemper*; as thoſe of the admirable cartoons, formerly at Hampton court.

The best method of compounding the colours with the vehicles, is to mix the colours in water; then to levigate the colours in part of it, and afterwards to put each kind into a proper pot, adding as much more of the melted size as will bring it to a due consistence, and mixing the whole well together in the pot, with a proper brush or wooden spatula. Warm water may be afterwards added, if necessary, for grinding the colours, or for working.

The pots must be tied with bladders. This method of painting is chiefly confined to fences, and groffer works, where the effect depends more upon the perspective art, and opposition of the colours, than on their brightness.

DISTENSION, the act of stretching a thing; also a state of a thing violently stretched, and distended. See **TENSION**.

DISTENSION, *Distensio*, *Διένσις*, in the *Ancient Music*, was used for the differences of sounds with relation to acute and grave. Wallis's *Append.* ad *Ptolem.* Harm. p. 154. Nature in this respect, strictly speaking, assigns no limits. But, with regard to our use, the ancient musicians held, that the nature of what sounded, and also of what was to judge, that is, the human ear, was to be considered: for, neither the human voice, nor even any instrument, can give intervals or *distensions* immenely great or small, nor could the ear judge of such. Aristoxenus fixes the least interval or *distension* in practice, to the *distis enharmenica*. As to the greatest, he thinks it does not exceed two octaves, and a fourth, or a fifth, if we consider any human voice, or three octaves, if we consider one and the same instrument. He does not deny that the extent of the voice, considered in different subjects, as in men and children, may go even beyond four octaves. Aristoxen. p. 21. edit. Meibom.

DISTICH, *Διστίχον*, a couplet of verses; or a piece of poetry, the sense whereof is comprehended in two lines. There are excellent morals in Cato's *Distichs*. See Vignuel de Marville on the *Distichs* of Cato, tom. i. p. 54, 55. Hexameter and pentameter verses, otherwise called elegiacs, are disposed in *distichs*.

DISTICHIASIS, in *Medicine*, a disorder of the eye-lids; wherein, instead of one, they have two rows of cilia, or hairs.

The word is formed of *dis*, twice, and *cilix*, or *cilices*, order, rank.

In the *distichiasis*, over the common, and natural hairs, there grows another extraordinary row, which frequently eradicates, and tears up the former; and, pricking the membrane immediately inswelling the eye, occasions pain, and draws defluxions upon it.

It is cured by plucking up the second rows of hairs with nippers, and cauterising the pores out of which they issued.

DISTICHOUS Stalk, in *Botany*. See **STALK**.

DISTILLATION, or **DISTILLATION**, in *Chemistry* and *Pharmacy*, the art, or act, of separating, or drawing off the spirituous, aqueous, oleaginous, or saline parts of a mixed body from the grosser and more terrestrial parts, by means of fire; and collecting and condensing them again by cold.

The use of *distillation* is very great; it being by means hereof that waters, spirits, essences, and extracts, are chiefly made.

Distillation is usually performed by means of fire raised to a greater or lesser degree, as circumstances require.

The fire is either applied immediately to the vessels wherein the matters are to be *distilled*, or it is applied mediately, by means of water, sand, iron filings, &c. These different methods of applying the fire, are called *bath*, *balneum*; *balneum Mariæ*, or *maris*; *balneum ardensum*, &c. They are also called *baths*; as sand-bath, water-bath, &c.

Distillation is twofold: 1. *Per ascensum*, by ascent; when the matter to be *distilled* is above the fire, and the spirit, or other principle, is raised from it.

2. *Per descensum*, by descent; when the matter which is to be *distilled* is below the fire, and the vapour drawn from it is precipitated to the bottom of the vessel.

Distillation by ascent is either *right*, or *oblique*.

DISTILLATION, *Right*, is performed with a common **ALMBIC**, or cucurbit; wherein the liquor is raised, and descends again, in form of drops, into a receiver. This is chiefly used when the texture of the body is such as allows of an ascent, as in vegetables.

DISTILLATION, *Oblique*, is performed sideways, and in crooked vessels, as **RETORTS**. This has been called *distillation per later*. Its use is, for such bodies as consist of heavier particles, and which cannot be raised without a strong impulse, nor even by the strongest, to such as the top of the almbic; of which kind are almost all minerals and metals.

Mr. Woulfe, F. R. S. has contrived an apparatus for

distilling a variety of substances, by which the fumes of vapours, that usually escape in the ordinary method of *distillation*, and are often injurious to the lungs, are condensed by passing into water, or some other fluid. See *Tab. Chemical Vessels*, fig. 7. A is a retort, in the room of which may be substituted, on some occasions, an iron pot, with a stone ware head, having its neck inserted into the receiver. B is a receiver, into the neck of which that of the retort is inserted: this has a spout at its bottom, through which the distilled liquor passes into the bottle C, and an opening in the side at D, into which one end of a tube, bent at right angles, is inserted: the other end of the tube passes into a vessel H, open at both ends, having its lower opening closed with a glass stopple. Through the upper mouth of the vessel H, one end of another tube I, bent twice at right angles, passes, while the other end is inserted into a bottle F, and immersed in the water or other fluid contained in that bottle. The crooked tubes are fitted into the mouth of the vessel H, by means of a cock, in which are two semicircular notches, through which the tubes pass, and by lute. The tube which passes into the bottle F is fitted into its mouth by means of a cock, with a semicircular notch, but without lute. The vapour that is raised from the substance exposed to heat in the retort, passes into the receiver B, where part of it is condensed, and flows into the bottle C, while the rest of it passes through the tube at D into the vessel H. From this vessel the vapour that remains still uncondensed passes through the crooked tube I into the water contained in the bottle F, by which it is all condensed excepting some elastic air, which is extricated in almost all *distillations*. This elastic

air rises through the water, and escapes at the semicircular notch of the cock in the mouth of the vessel, which on this account is not accurately closed with lute. In most *distillations*, a quantity of air is absorbed at different times during the process; and in this case the external air will press on the liquor in the bottle F, and force it through the tube I, into the vessel H, from which it may be taken by opening the stopple L. The use of the vessel H is to receive the liquor that may be thus raised from the bottle F, and to prevent it from passing into the receiver B, and from thence into the bottle C, where it might spoil the distilled liquor. By *distilling* 12 lb. of British sal ammoniac with 20 lb. of quick-lime and two gallons of water, Mr. Woulfe obtained 84 lb. of volatile alkaline spirit, strong enough to make *essence de luce*, which was collected in the bottle joined to the receiver; and on adding two other gallons of water, he obtained 7 lb. of weak volatile spirit. Two stone gallon bottles, with three quarts of water in each, were successively made use of to condense the vapour; as the one was heated by the fumes, the other was substituted in its room; and by the condensed vapour, the fix quarts acquired an increase of 24 lb. in weight; and it appeared from experiments made with a view to compare the strength of the alkali thus condensed by water with that of the strongest alkaline liquor first obtained, that a pound of the former was to a pound of the latter as 120 to 260; so that the quantity saved was nearly equal to 5 lb. of volatile alkali, which would have been lost by the common method of *distillation*. Mr. Woulfe observed a singular difference betwixt the alkaline liquor collected in the bottle joined to the receiver, and that condensed by the water in the bottle F; a considerable heat was excited by mixing the latter with the vitriolic acid, whereas there was no heat in a mixture of the former with the same acid.

Mr. Woulfe likewise *distilled* 14 lb. of common salt with an equal quantity of oil of vitriol, diluted with 7 lb. of water, and collected 9 lb. 54 oz. of spirit of salt in the bottle C, and 6 lb. 12 oz. of the same spirit condensed in six quarts of water in the bottle F; and the residuum weighed 18 lb. 6 oz. so that there was a loss of 8 oz. or 74th of the whole, most of which was probably elastic air. The strength of the acid condensed in water was found to be to the strength of that collected in the bottle C, as 200 to 109; so that the 6 lb. 12 oz. of the former is equal to near 13 lb. 1 oz. of the latter, and so much was saved by this method of *distillation*.

He observes, that the slower the *distillation* was conducted, the more concentrated were the acid vapours condensed in water; and that the most concentrated portion of the acid of sea-salt is the most volatile; and that in strength it is to the vitriolic acid, whose specific gravity was to that of water as 24 to 13, in the proportion of 442 to 31; and moreover, that the vapour of spirit of salt condensed in water contained no vitriolic acid, though the spirit collected in the bottle C contained some of that acid. Mr. Woulfe formed a machine **ATHER**, by applying the vapour of rectified spirit of wine to this very concentrated vapour of spirit of salt.

and condensing the combined vapours in spirit of wine. The process for this purpose was briefly as follows: the necks of two retorts, one of which contained the spirit of wine, and the other the sea-salt and vitriolic acid, from which the marine acid was to be distilled, opened into one receiver, where the vapours meet; from this receiver the vapours passed through a tube into spirit of wine contained in a bottle; and those which were not there condensed, passed through another tube into spirit of wine contained in a second bottle. By a farther distillation and cohobation, with flaked lime, of the several liquors collected in the receiver, and in the spirit of wine in which the vapours were condensed, a very subtle penetrating æther was produced. The apparatus for this purpose is represented in fig. 8. B is a glass tubulated retort, coated with loam up to B, and placed in the furnace A: D is another tubulated retort fixed in a vessel with sand in the furnace C. E is a stone vessel, in which the vapours of B and D are combined together; F is the bottle for receiving the liquor which distills; G is a tube about three quarters of an inch bore fitted to E, and H a crooked pipe about a quarter of an inch bore; I and K are glass vessels containing spirit of wine, and L is a crooked glass tube.

Mr. Woulfe apprehends that his method of condensation may be applied to the distillation of vitriolic acid, to the rectification of phosphorus, the vapours of both which substances should be condensed by means of water; to the rectification or distillation of vitriolic æther, the vapours of which should be condensed in spirit of wine; and to many other distillations. Phil. Trans. vol. lvii. for 1767. art. 50. or Dict. Chem. vol. iii. ad fin.

DISTILLATION by descent, is where the fire is applied on the top, and all around the vessel, whose orifice is at the bottom; and, consequently, the vapour not being able to rise upwards, it is forced to precipitate, and distill down to the bottom. This method of distillation has many faults, is absolutely unnecessary, and is entirely neglected.

There is a second kind of distillation by descent, called *per deliquium*; which is a natural liquefying, or resolving, of salts into a liquor, by means of moisture.

In the resolution of simples, an excellent method to preserve their virtues is, in lieu of fire, or any other foreign heat, which might alter or destroy these virtues, to make use of the heat of a dunghill made of putrefied herbs.

The process and measures of distillation are very different, according to the different subjects to be distilled. Care should be taken that no greater heat is applied than is just necessary to raise the substances to be distilled: this is proper, both for the success of the operation, and for preventing the breaking of the vessels.

Acid spirits are usually drawn into a *reverberatory FURNACE*, and with a vehement fire; ponderous woods, as guaiacum, box, &c. are distilled in a retort, after the same manner. In these, first comes a little phlegm, and then, the fire increasing, the spirits fly out in white clouds: when they cease to come, the matter in the receiver is filtrated through a tuncel, which lets pass the spirits, leaving a black fetid oil behind. See CONCENTRATION.

Odoniferous plants, as balm, wormwood, sage, hyssop, &c. are distilled by the *COCURBIT*, or vesica; first pouring a strong decoction of the same plant hot upon the plant itself bruised, or adding common water to the plant, whether dry or fresh, cut with threes into small pieces, and letting the whole digest in a close vessel two days: then about half the water, or spirit, is drawn away by distillation; and what remains, being pressed, filtrated, and evaporated, to the consistence of honey, is the extract of the plant. Lastly, drying what remained in the cloth after expression, and burning it, they make a lixivium of its ashes; which being filtrated, and evaporated to dryness, what remains is the fixed salt of the plant.

Plants not odoniferous, are sometimes managed thus: the plant, being pounded, and two thirds of the stem-bark, or retort, filled with it, they pour a good quantity of the expressed juice of the same plant upon it, so as the bruised matter may float therein, without sticking any where to the vessel; then they draw off about half as much water as there was juice, which is the distilled water of that plant: what remains being pressed in a cloth, and the juice settled, they filtrate, and evaporate it to two thirds; and, setting it in a cool place, the essential salt floats into crystals.

There is a method of **DISTILLING cold**; which is thus performed; they take, for instance, four pounds of flowers, more or less, and put them in three or four pints of water, and put the whole in a limbeck, which they lute exactly; then place it in a vessel half filled

with ice, beaten and salted, as if they meant to freeze the water; then fit on a receiver, and lute it well: then, wetting a linen cloth in hot water, they cover the limbeck-head therewith, repeating this several times; by which means, the finest parts are raised from the flowers. But care must be taken, that all the superfluous water bath been first emptied out of the limbeck.

Dr. Beal, in the Philosophical Transactions, mentions an extraordinary kind of cold distillation, viz. made by frost and cold air: his thermometer being exposed out of doors, during the severe frosts of 1665, fine clear drops, like dew, ascended to the top of the tube, which afterwards, in time, re-descended into the stem, and filled the space of half an inch; and, though the spirit of wine itself was tinged very deep, yet this second spirit was clearer and brighter than any crystal. The like he did by exposing his thermometer to the hot air in the middle of summer; and hence takes occasion to recommend a farther prosecution of this pyrotechnia.

The ascent of fluids, we are taught by philosophy, is effected two ways: 1. By their specific gravity; and, 2. By impulse.

The first way of elevation is manifest, from this lemma, viz. that particles of bodies which swim in any fluid, if they be specifically lighter, must be borne upwards by that fluid; hence, as distilled liquors are carried upwards through the air, it is to be inquired, how they come to be specifically lighter than air.

Now, a fluid will be specifically lighter than another, when, under a larger surface, it has an equal, or a less gravity: according to this proportion, the bulk of the fluid ought to be increased in distillation; and how easily, by the help of fire, it may be increased, or, which is the same thing, rarified, will appear, from what we have said under the articles **HEAT**, and **RAREFACTION**.

It is known, by computation, that the proportion of the specific gravity of water to that of air, is something more than as eight hundred to one: hence, therefore, similar spheres, or solids, are as the cubes of their diameters; and the specific gravity decreases reciprocally in the very same proportion as the cubes of the diameters increase; in order to make a particle of water lighter than a particle of air, no more is necessary than to rarefy it till its diameter becomes ten-times greater; which, in this case, is but a very small degree of rarefaction: for the cube of the diameter, in a particle so rarefied, is 1000: if the diameter be made eleven times greater, the cube will be 1331; and if twelve, 1728: so that water, when rarefied but twelve degrees, will be above doubly lighter than air; and if the rarefaction be carried on farther, it may easily be collected from the increase of the numbers, that a particle of water may be rendered almost infinitely lighter than air. Now, the elevation of bodies equally fluid, and heavy, is always proportionable to their different aptitude to be rarefied; that is, they ascend quicker, upon the application of any force, the more susceptible they are of rarefaction: but, in bodies whose aptitude to rarefy is equal, the time of ascent is to be determined by their specific gravity.

But it is not only specific gravity that serves to elevate bodies in distillation; but an external impulse may also cause their ascent: the impulse we have here to do with, comes from the fire; whose particles, though extremely small and light, yet may raise bodies much heavier than themselves, by acting upon them with a certain degree of force. For since the moment of a body, or that force by which it acts upon another, is in a compound ratio of the quantity of matter, and celerity; the celerity may be so increased, as to give a sufficient force to the body, though the quantity of matter in it be ever so small. Let some heavy body, therefore, be supposed to descend, with no other moment than what it receives from its own gravity; in this case, then, the air, which is much lighter, may be moved with such celerity, as not only to sustain that body, but to mount it up higher; and the more rapid the impetus of the air is, or the surface of the body more distended, the higher and swifter will the elevation be.

So fire, though it be a body of the minutest size, may be moved with that rapidity, as to acquire and communicate what force can be desired towards removing any obstacles. When, therefore, the moment of fire is augmented in the manner explained, so as to exceed the force of the distilled body, it will remove it from its former situation; or, what is here the same thing, because the direction of its motion tends upwards, it will carry it up. And thus, particles specifically heavier than the air contained in the retort, as those of acid spirits are, ascend by a more violent impulse of the fire used in distillation.

Another thing to be noted, is, that the same quantity of matter is elevated so much the easier, in proportion as the

the surface is enlarged: for the more this is diffused, the more particles of fire it receives. Having, therefore, this united force to drive it up, it more easily ascends; so that, by the same degree of fire, bodies will not equally arise, though they are equally heavy, if there be that difference in their surfaces already supposed.

The air, also, has no small share in the business of an impulse: for, being rarefied by the fire, it is not only impelled upwards itself, but it carries other particles up with it: and it may be learned, by many very familiar experiments, what impetus bodies, so rarefied, exert. Whoever, therefore, well considers these things, viz. specific levity, an impelling force, and the extent of surface; and what may be effected by them; and how many ways, and in what proportions, all of them may be changed; will very easily account for all the variety which is found in the several processes of distillation.

DISTILLATION, COMBINATORY, a term introduced into use by Dr. Shaw, in his Essay on Distillation, to express that sort of rectification of distilled spirits which is done with ADDITIONS; and which he otherwise calls improper rectification, by way of distinction from that proper rectification, which is the only method of reducing a spirit to its utmost degree of purity and perfection.

In the *combinatory distillation*, many ingredients are added in order to rectify the spirit, as the distillers express it; and some part of these actually come over and mix themselves along with the spirit so intimately, as not to be separable again without great difficulty. This is done with a design to alter, improve, or abolish the natural flavour of the spirit; but instead of rectifying it, they only obscure and pervert its true qualities. In the business of rectification, properly so called, of the malt spirit, all that is necessary is the re-distilling of the low wines procured from the wash; the again distilling over of the spirit thus obtained, and called proof spirit, into a totally inflammable liquor called alcohol. This is done by the common process, only taking care not to increase the fire by sudden spurts, so as to raise the oil with the spirit, which if once mixed will not be easily separated again, and scarce ever perfectly, whatever care is used.

The methods of combinatory rectification, on the other hand, are very numerous, every distiller having his peculiar nostrum about it. Malt spirit is the general subject of this process, and the means used to rectify it on this plan may be reduced to three heads. 1. That by fixed alkaline salt alone. 2. That by fixed alkaline salts and acid spirits. And 3. That by saline bodies and flavouring additions. The general method is that by fixed alkaline salts alone; but it is surprising to see in how careless and slovenly a manner this is done by the generality of our distillers, though we are allowed to excel all other nations in it. The effect of this operation, when carefully performed is to attenuate and thin the spirit, and to keep back a part of its gross and fetid oil, and so far to alter the part of the oil which comes over, as scarce to leave the spirit distinguishable for a malt spirit.

This end is greatly promoted by a prudent and steady management of the fire, and by leaving out the faints; but this is a thing our distillers never attend to: they hurry over the operation, working the still in its full force, and by this means raise and carry over the oil; though the whole business of the process is to keep it back; and they even suffer the fullness bitter oil, made into a kind of liquid soap with the salt in this process, to run among the spirit with the faints; by this the whole intent of the process is frustrated, and the spirit rendered much harder to clean than it was before.

This operation is usually performed upon proof spirit, and the quantity allowed is from eight to fourteen pounds of salt of tartar, fixed nitre, pot-ash, or more commonly calcined tartar, to the piece. The tartar being only roasted to a blackness in this last process, is sold under the absurd notion of a vinous salt; and the dealers will often praise the vinosity of their spirit, because distilled from this salt; but the truth is, that this salt never fails to give, instead of a vinosity, a saponaceous, urinous, or lixivial taste and smell. This is the great misfortune that attends the method of rectifying by means of fixed salt, for they all of them become volatile in part during the operation; and this volatile portion passes over the helm with the spirit, and impregnates it, uniting itself also with that portion of oil yet retained in the spirit, and much more firmly combining it and the spirit together than they were before; so that in reality the spirit thus rectified is no other than an alkaline or tartarified spirit, as the chemists call it, a thing extremely different from a true vinous spirit.

This method, therefore, though it were practised to the utmost perfection, would never do what was intended by it, but would alter, instead of rectifying the spirit.

Hence there appears the necessity of some acid to deaden the force of the alkali thus used in the rectification. The necessity of this, gave occasion to the method of mixing acids and alkalis together for these purposes. The acids used by our distillers on this occasion, are those of the mineral kingdom, because of their cheapness; and the most common in use among them are oil of vitriol, spirit of nitre, oil of sulphur, and the like. The most celebrated rectifiers in the malt way have got their reputation by the use of these acids. There is some choice, however, to be made of the spirits according to the greater or lesser foulness and need of rectification, and they must not only be well proportioned, but carefully introduced, and regularly mixed; and indeed without some skill and judgment in the management of these corrosives, no distiller ought to attempt to meddle with them.

These strong and violent acids at best are not so well adapted to the work as the milder ones, particularly the sulphureous spirit of vitriol, which comes over in the rectification of the oil; to this may be added the common *spiritus nitri dulcis*, and Mr. Boyle's acid spirit of wine well prepared.

Some of our rectifiers, instead of the fixed salt, use quick-lime, which cleanses and dephlegmises considerably; but this method requires the assistance of acids also afterwards, to take off not only the alkaline disposition, but also the stinking flavour it leaves behind it. Some also use chalk, virgin earth calcined, and burnt animals bones. These are of considerable use in the rectifying of brandy without rendering the spirit any more unfit for the purpose of the compounders than before, or requiring much acid afterwards.

The great art of using the flavouring ingredients in rectification, is the proper admixture of salts in the operation, for without these the flavours added by this means do very little. The salts used on this occasion are either the fixed alkalis, as pot-ash and calcined tartar, or decrepitated common salt, or calcined vitriol, alum, or sandiver. The flavouring ingredient is to be applied afterwards, and the whole quantity of the spirit either drawn over again, or not, as the occasion and nature of the addition requires. But these saline bodies perform so very little, that the spirit is usually left impregnated with a flavour from its own oil, which is but badly hidden, or overpowered by the other ingredients. The most common flavourers, as they call them, are these: mace, orris-root, parsnip, artichok, rhodium, raisin-stalks, damask-roses, wine-lees, rape or grape-hulks, and the oil of wine. The last of these is infinitely preferable to all the others, but is not so well known. These and the like ingredients judiciously mixed, will, when the spirit is very well purified first, give the flavour of foreign brandies with some tolerable exactness; but if this is not attained, their flavour will be lost in the original one, and the general taste resulting from the whole will be like nothing at all. The ultimate perfection aimed at in all the processes of *combinatory distillation*, is the separating of the English malt spirit at one operation, so as to render it tasteless and inodorous, and yet vinous; or else to make it resemble the French brandy, arrack, or some other low-flavoured vinous spirits.

This is certainly practicable, though not usually practised to the perfection that it might be: the principal thing to be endeavoured after, is the obtaining of a tasteless spirit, capable of receiving any impression, and then the business of flavouring is easy. The method of rectifying, by fixed alkaline salts, is capable of great improvement, as by steeping the spirit first brought near to the state of alcohol, upon a well-dried salt of tartar, or any other cheaper, but pure fixed alkali; by this means it will be almost totally freed of its oil without volatilising much of the salt, as it does in the way of distillation: by this means a weak inclure of salt of tartar may be procured, and an acid added to this, to take off the effects of the alkali in the spirit; the whole is then to be distilled, and the fire being well managed, a very clean spirit will be thus procured at one operation, such as can no way else be obtained at once.

The use of the compound neutral salts in rectification seems not yet to be sufficiently known; what is meant by these salts is a fixed alkaline salt saturated with an acid one. Such a salt has indeed been expected from the *copos mortuum*, or white saline cake, remaining upon the distillation of the spirit of nitre with oil of vitriol; but it proves too hard, stony, and insoluble, to be of any great use on this occasion: a much better effect may be expected from soluble tartar, carefully prepared, and properly used; though even this is apt to render the spirit a little saponaceous. Some compound neutral salts have been made, however, upon this foundation, that would rectify common malt spirit from proof at a single operation.

tion, much better than all the other more perplexed and tedious methods in use. A prudent use of fine dry sugar may also be of some service, as it readily unites with the essential oil, and detains and fixes it without imparting any unwholesome or other nauseous flavour to the spirit rectified upon it. Another hint to this purpose, which may be made to turn to very good account, is that given by the ingenious method invented by Dr. Cox, of taking all the oil out of the volatile salts, by first bringing them to a neutral state with the spirit of salt, and then subliming them with salt of tartar, which does the business to perfection. In the case of spirits the acid may be varied, and virgin-earth, chalk, calcined flints, or the like absorbents used instead of salt of tartar, and yet the general effect will be the same. Shaw's Essay on Distillery.

DISTILLATION, Brewing for. See BREWING.

DISTILLATION of salt water, in order to obtain fresh. See SALT-WATER.

DISTILLED Juice of tor. See TAR-water.

DISTILLED Waters. The waters distilled from plants and other medicinal things, may receive something from the vessels in which they are distilled, which may in some degree alter their properties. Even water alone distilled in glass vessels, and in those of metal, differs so much, that these two distillations being mixed, will render one another turbid. The Florentine academicians have taken this change of waters under their consideration, among the many other minutiae of natural and experimental philosophy omitted by others. They found that common water distilled in leaden vessels would render all other waters turbid, on mixing with it; whether it were spring, fountain, river, or well water, except alone the water of the conduit at Pisa: an experiment that proved a quality in that water, different from all others, though never before suspected in it. The experiment being repeated at various seasons afterwards, the water of this conduit was sometimes found to grow turbid also; but this was at such times as other waters, from rain, &c. had blended themselves with the genuine water of the spring. Waters distilled in glass vessels, and mixed with waters distilled in lead vessels, were supposed by the Florentines indeed not to render one another turbid; but, by the observations often made by the curious Redi, it proved that they did. See Redi's Observat.

Common water distilled in gold, silver, or glass, with a glass head, and kept in glass, remains always clear; but, in crystal of Pisa, it grows turbid in a few hours, then milky, and in a few days yellow, and after all this bitter; whereas in crystal of Rome or Venice, the same water does not grow turbid till after two or three days, and never becomes yellow or bitter in it; and in crystal of Paris it will scarce grow turbid, but after a very considerable time. The various materials used in the making of these several kinds of crystal, at the glass-houses of these different places, and the various manner of working them, are the occasion of this great difference in them; and on these principles we may find a new and more than ordinary way of judging of the goodnests of glasses, which seem equal to one another. See WATERS.

DISTILLED Waters of laurel-leaves. See LAUREL.

DISTILLER, a person who distils spirits for sale. Such a person is liable to the duties; and is not allowed to have any still or number of stills, which singly or together contain less than a hundred gallons under the penalty of 100*l.* and the wash-still shall contain at least four hundred gallons, exclusive of the head, under the same penalty. 2 Geo. III. c. 5. and 14 Geo. III. c. 73.

Distillers are to enter their warehouses, stills, and vessels, &c. at the next office of excise, on pain of 20*l.* and persons occupying any such stills forfeit 50*l.* and the vessels are to be marked by the ganger. 8 and 9 W. c. 19. 22 Geo. II. c. 40.

Distillers who use private pipes, &c. for conveyance of distilled liquor, forfeit 100*l.* 10 and 11 W. c. 4. They shall also make holes in the breast of the still for taking gages and samples and provide locks on the still-heads, the holes, discharge-cocks, and furnace doors, under a penalty of 50*l.* and of 200*l.* for breaking or wilfully damaging such lock or furnishing, after it has been secured by the officer. 12 Geo. III. c. 46. 14 Geo. III. c. 73.

Distillers are required to give notice to the officer of excise, before they receive any wine, cyder, &c. or any kind of fermented wash, on pain of 50*l.* and also before they charge or open the still, expelling and describing the number and marks of the wash-batches used; and they are prohibited from charging the still with any other, under a penalty of 120*l.* 24 Geo. II. c. 40. 12 Geo. III. c. 46. 14 Geo. III. c. 73.

Distillers, in preparing grist for wash, that use more

wheat than in the proportion of one quarter of wheat to two quarters of any other grain, forfeit 50*l.* 23 Geo. II. c. 9.

Excise officers may enter warehouses, &c. used by distillers and dealers, to take account of liquors, by day or night; and persons obstructing them forfeit 50*l.* 6 Geo. I. c. 21. and 5*l.* a gallon is forfeited for all liquors concealed, 3 W. c. 15.

Retailers of distilled liquors, or such as sell the same in less quantity than two gallons, must take out a licence which is to be granted only to those who keep taverns, victualling-houses, inns, coffee-houses, or ale-houses; who, within the limits of the head office of excise in London, pay 10*l.* a year rent and parish rates, and in places where the occupiers are not rated, 1*l.* a year; and who, in other parts of the kingdom, pay to church and poor. They must first be licensed to sell ale in the places where they dwell. Retailers without licence forfeit 10*l.* which may be either levied, and is in no case to be mitigated below 5*l.* or the offender may be committed to hard labour for two months; and by another act, the forfeiture is 50*l.* 16 Geo. II. c. 8. 17 Geo. II. c. 17. 24 Geo. II. c. 40. 16 Geo. II. c. 12. 9 Geo. III. c. 6. 13 Geo. III. c. 56. Hawkers of spirituous liquors in the streets, &c. are liable to a forfeiture of 10*l.* 9 Geo. II. c. 23. 11 Geo. II. c. 26. Persons giving away spirituous liquors, or paying wages in them, shall be deemed retailers. 9 Geo. II. c. 23. Keepers of gaols, work-houses, &c. selling spirituous liquors, or knowingly suffering them to be sold, except such as are prescribed by a physician, surgeon, or apothecary, forfeit for the first offence 100*l.* and for the second their office. Debts for spirituous liquors cannot be recovered, unless they have been contracted, or the liquors delivered at one time to the value of 20*l.* or upwards; and distillers knowingly selling or delivering distilled liquors to unlicensed retailers, forfeit 10*l.* and treble their value; and the retailer, convicting the distiller, is entitled to a share of the penalty, and is himself indemnified. Persons riotously refusing officers, or assaulting informers, and their aids or abettors, are guilty of felony, and liable to seven years transportation. 22 Geo. II. c. 40. No liquor exceeding one gallon shall be removed without a permit. 6 Geo. I. c. 21. British spirits made from corn are allowed on exportation as merchandise, a bounty or drawback of 3*l.* 12*s.* per ton; provided that they are not exported in casks containing less than a hundred gallons, and in vessels of less burden than a hundred tons; except to Africa and Newfoundland, whither they may be exported in any vessels of more than seventy tons 2 Geo. III. c. 5. and 6 Geo. III. c. 46.

DISTILLERY, the art of distilling BRANDY and other spirits. This art was first brought into Europe by the Moors of Spain, about the year 1150: they learned it of the African Moors, who had it from the Egyptians; and the Egyptians are said to have practised it in the reign of the emperor Dioclesian, though it was unknown to the ancient Greeks and Romans. Anderson's Hist. of Commerce, vol. i. p. 83. See FERMENTATION, and MALT distillery.

DISTINCT notion, or idea, according to M. Leibnitz, is, when we can enumerate marks and characters, enough whereby to recollect a thing.

Such, e. gr. is this; that a circle is a figure bounded with a curve line that returns into itself; all the points whereof are equally distant from one middle part. Or, it is that wherein the mind perceives a difference from all other ideas.

Distinctive base, in Optics, is that distance, from the pole of a convex glass, in which objects, beheld through it, appear distinct, and well defined: so that the distinct base coincides with what we otherwise call the focus. The distinctive base is caused by the collection of the rays proceeding from a single point in the object, into a single point in the representation; and therefore concave glasses which do not unite, but scatter and dissipate the rays, can have no real distinctive base.

DISTINCTION, a diversity in things, or conceptions.

Logicians define *distinction*, an assemblage of two, or more words, whereby disparate things, or their conceptions, are denoted.

There are three kinds of *distinctions*, taken from the three different modes of existence: the first *real*; the second, *modal*; and the last *rational*.

DISTINCTION, Real, is that between things which may exist, or be conceived to exist, apart from each other: such is that between two substances, or the modes of two substances.

DISTINCTION, Modal, is that between several things, one whereof may exist without the other; but not *vice versa*, the other without that: such is that between the mind, and

and an act of will; between wax, and its hardness; water, and its freezing, &c.

DISTINCTIO Rationis, or Rational DISTINCTION, is that between several things, which are really one and the same, and whereof one cannot exist without the other, nor, *vice versa*, the other without this: such is that between a thing, and its essence; between the essence, and properties, &c.

Of this distinction some authors admit two kinds; the one barbaously called *Rationis ratiocinatio*, having some foundation in things; as when we distinguish the justice of God from his mercy: the other called *ratiocinatio ratiocinantis*, which has no foundation at all; and therefore is, by many, quite rejected.

Though others contend, that there is no distinction *ratiocinantis*, but is, at the same time, a *real distinction*: thus, say they, God, and just God, are, to each other, as milk, and white milk; and a just God, and merciful God, a white milk, and sweet milk. But when I say, milk is distinguished from white milk, or white milk from sweet milk, the distinction falls between whiteness and sweetness, which is a *real distinction*. See **REALISTS**.

DISTINCTION, Metaphysical, called also by the schoolmen *aliqua, altera, et diversitas*, is a non-agreement of being, whereby this entity is not that, or one thing is not another.

DISTINCTIO, or DISTINGUO, in the *Schools*, an expedient to evade an argument, or to clear up, and unfold an ambiguous proposition, which may be true in one sense, and false in another. The respondent was hard pressed, but he disengaged himself by a *distinction*. Moliere makes T. D. say to his mistress, who had told him, he must submit to the will of a person he loved: *Distinction, Mademoiselle, pour l'intérêt de son amour, Concédez-moi la passion, Nèze*.

DISTORTION, in Medicine. **DISTORTIO oris**, or **DISTORTION of the mouth**, is a contraction, or shortening of one side of the mouth, occasioned by a convulsion, or a palsy of the muscles of one side of the face.

When a *distortion* arises from a convulsion, it is on the same side with the convulsion, the force of the convulsed part being superior to that of the sound part: on the contrary, when it arises from a palsy, it is on the opposite side, the paralytic part being here surmounted by that which is sound.

In a *distortion of the mouth*, the patient can only spit on one side; and if he laughs, or pronounces the letter O, he only moves one side of his mouth.

The Greeks call this disorder *εναρτοσ αμμοσ, σπασμοσ ομμοσ*. This malady is often the effect of carelessness and ill habits. A remarkable instance of this kind is mentioned by Winlow; in which, by carelessness, dressing, and leaning, the back-bone of a young lady became crooked, and bent sideways in contrary directions, like the letter S.

DISTORTION of the eye, is called also **SQUINTING**, or **STRABISMUS**.

DISTORTOR oris, in *Anatomy*, a muscle of the mouth, called also **ZYGOMATICS**.

DISTRACTION, in Medicine, sometimes denotes the act of pulling a fibre, membrane, or the like, beyond its natural extent; and what is capable of this enlargement, is said to be *distrahile*.

DISTRAIN, in Law. **To DISTRAIN**, is to attach, or seize on one's goods, for the satisfaction of a debt.

DISTRESS, in Law, a compulsion resorted to in certain real actions, for bringing a man to appear in court, or pay rent, or other duty denied; and by the common law, *distresses* for rent were not to be sold, but only detained for enforcing payment of the rent; but this is altered by statute.

The method of *distress* for rent has been much altered in this case. If any tenant of lands or tenements shall fraudulently carry away his goods, to prevent *distress*, the landlord may within thirty days after *distress* them wherever they shall be found, as if they had been on the premises; but no such goods shall be *distressed*, if sold, *bona fide*, for valuable consideration before seizure, to any person not privy to the fraud. Tenants committing such fraud, or others assisting, shall forfeit double the value of the goods carried off, to be recovered by action of debt, &c. and where they shall not exceed fifty pounds value, the landlord may exhibit a complaint before two justices of the peace, who are to examine the fact, and enquire into the value of the goods, and thereupon order the offender to pay double value, leviable by *distress* and sale; or for want thereof, commit the offender to the house of correction for six months. Landlords or their agents may, with the assistance of a constable, seize any goods fraudulently concealed in any house, out-house &c. And in case of a dwelling-house, on oath first made to some justice, or reason to suspect that such

goods are therein, may break open the same, and *distress* them. They may also *distress* for rent, any cattle, or flock of their tenants, feeding on any common; or corn growing on the land, which they shall cure, and lay up when ripe, in any proper place, giving notice to the tenant within a week where lodged; and dispose thereof toward satisfaction of the rent and charges; the appraisement to be taken when cut and cured. But if after *distress* so taken, before the product be ripe and gathered, the tenant shall pay the rent, and charges of the *distress*, the said *distress* shall cease. Persons may secure *distresses* lawfully taken, and sell them upon the premises, in like manner as may be done of the same, by 2 W. and M. and any persons may go to and from the premises, to view, appraise, buy, or take away the goods of the purchaser; and if a recous be made for the *distress*, the persons aggrieved shall have the remedy given by the said statute. Stat. 11 Geo. II. cap. 19.

The usual effect of *distress* is to drive the party *distressed* to replevy the *distress*, and to take his action of trespass against the *distrainger*; or else to compound with him for the debt, or duty, for which *distress* was made.

There are several things not *distressable* for a *distress* must be of a thing, whereof a valuable property is in somebody; and, therefore, dogs, bucks, conies, &c. that are *feræ naturæ*, cannot be *distressed*.

Again although it be of a valuable property, as a horse, (yet when a man or woman is riding on him) or an ax (in a man's hand cutting wood) and the like, are for that time privileged, and cannot be *distressed*.

Again, valuable things shall not be *distressed* for rent, which are for the benefit and maintenance of trades, and which, by consequence, are for the commonwealth, and are by the authority of the law there; as an horse in a smith's shop; materials in the weaver's shop for making cloth; cloth, or garments, in the tailor's shop; sacks of corn, or meal in a mill, or a market; nor any thing *distressed* for damage feasant, for it is *castella legi*.

Again, nothing shall be *distressed* for rent, which cannot be rendered again in as good a plight as it was at the time of the *distress* taken; as sheaves or flocks of corn cannot be *distressed* for rent, but for damage-feasant they may. Again, benefits belonging to the plough shall not be *distressed*.

Lastly, furnaces, cauldrons, or the like, fixed to the freeholds, or doors, or windows of an house, or the like, cannot be *distressed*; when a *distress* is taken that has life in it, it must be brought into the common pound, or kept in an open place, where the owner may give it food.

Distress is divided, by Briton, into *real* and *personal*.

DISTRESS, personal, is made by *distressing* a man's moveable goods, and seizing all the profits of his hands and tenements, from the teste, or date of the writ, for the defendant's contempt in not appearing to an action brought against him when he was summoned, or attached; and the issues so returned by the sheriff, are forfeited to the king, and eleated into the exchequer.

DISTRESS, real, is made on immovable goods. It differs from an attachment in this, that it cannot be taken by any common person, without the compass of his own fee; except it be presently after the cattle, or other things, are driven, or borne off the ground, on purpose to avoid *distress*.

Distress is also divided into *finite* and *infinite*.

DISTRESS, finite, is that limited by law, how often it shall be made to bring the party to trial of the action; viz. once, twice, &c.

DISTRESS, infinite, is without limitation, till the party come; as against a jury, which refuses to appear upon certificate of assize, the process is *venire facias, habere corpus*, and *distress infinite*.

Lastly, *distress* is again divided into *grand distress*, by Fitzherbert called *magna distress*; and *ordinary distress*.

DISTRESS, grand, is that made of all the goods and chattels the party has within the county.

DISTRIBUTION, the act of dividing a thing into several parts, in order to the disposing each in its proper place. See **DIVISION**.

DISTRIBUTION, in Architecture. **DISTRIBUTION of the plan**, denotes the dividing, and dispensing the several parts, and members, which compose the plan of a building.

DISTRIBUTION of ornaments, is an equal, orderly placing of the ornaments in any member, or composition of architecture. See **ORNAMENT**.

DISTRIBUTION, in Law, the surplus of an estate, or *par avire vic*, is distributable by administrators. See **ADMINISTRATOR**.

For the *distribution* of the estates of intestates, see **INTESTATE**.

DISTRIBUTION, in Logic, is a kind of division which distinguishes

tinguishes an universal whole into its several kinds or species. The rules of a good *distribution* are much the same as those of *division*.

DISTRIBUTIONS, *manus* and *quotidian*, in *Ecclesiastical Matters*, denote certain small sums of money, appointed by the donors, or founders thereof, to be distributed to such of the canons of a chapter as are actually present, and assiduous at certain offices.

DISTRIBUTION, in *Painting*, denotes the disposition of the objects and lights in a picture. See *CLARA-OBSCURE*.

DISTRIBUTION, in *Printing*, the taking a form asunder, separating the letters, and disposing them in the cases again, each in its proper cell.

DISTRIBUTION, in *Rhetoric*, is a kind of description; or a figure whereby an orderly division and enumeration is made of the principal qualities of a subject.

For example, He has understanding to see our faults, justice to restrain them, and authority to punish them. Their throat is an open sepulchre; they flatter with their tongues; the poison of asps is under their lips; their mouth is full of cursing, and lies; and their feet are swift to shed blood.

DISTRIBUTIVE, that distributes, from *dis*, *afunder*; and *tributus*, to give.

DISTRIBUTIVE, in *Justice*, is that whereby we give every person what belongs to him. See *JUSTICE*.

DISTRIBUTIVE, in *Grammar*. See *NUMERALS*.

DISTRICT, the territory, or extent of jurisdiction, of a judge.

A judge or officer, cannot act out of his own district. See *JUDGE*.

DISTRICT, in *Law*, properly denotes the place wherein a man has the power of distraining; or, the circuit, or territory, wherein one may be compelled to appear.—Where we say, *hæret de son fief*; others say, *extra districtum suum*.

DISTRINGAS, a writ directed to the sheriff, or other officer, commanding him to distrain one for a debt to the king; or for his appearance at a certain day. See *DISTRESS*.

DISTRINGAS *juratori*, a writ directed to a sheriff, whereby he is commanded to distrain upon a jury to appear, and to return issues on their lands, &c. for non-appearance. This writ issues for the sheriff to have their bodies in court, &c. at the return of the writ.

DISVELOPED, in *Heraldry*, is used much in the same sense with displayed. Thus colours, said in an army to be flying, are, in heraldry, said to be *disveloped*.

DISUNITE, in the *Mange*, is used for a horse that drags his haunches, that gallops false, or upon an ill foot. See *GALLOP*.

DITCH, in *Agriculture*. In marshes, and other wet land, where there are no hedges, the common fence or inclosure for land is a ditch. They allow these ditches six feet wide against high ways that are broad, and against common five feet. But the common ditches about inclosures, dug at the bottom of the bank, on which the quick is raised, are three feet wide at the top, one at the bottom, and two feet deep; by this means each side has a slope, which is of great advantage; for where they neglect this, and dig them perpendicular, they are always washing down; beside in a narrow bottomed ditch, if cattle get down into it, they cannot stand to turn themselves to crop the quick; but where the ditch is four feet wide, it should be two and a half deep; and where it is five wide, it should be three deep, and so in proportion.

DITCH, in *Fortification*, called also *foss* and *moat*, a trench dug round the rampart, or wall of a fortified place, between the scarp, and counterescarp. See *Tab. Fortif. fig. 21. lit. b b b*, &c.

Some ditches are dry; others full of water; each whereof have their advantage. The earth dug out of the ditch serves to form the rampart.

The ditch in front should be of such breadth as that the tallest tree may not reach over it, i. e. from eighteen to twenty feet, and about seven or eight feet deep; and the ditches on the sides are about ten feet wide, and six feet deep; though the rule others give for the dimensions of the ditch, is, that it afford earth enough to build the rampart of due magnitude. The space between the rampart and ditch, being about six feet, is called the *berm*, or *fig*.

DITCH-water. See *WATER*.

DITHYRAMBIC, something that relates to the *dithyrambus*. We say, a *dithyrambic* verse, *dithyrambic* poem, *dithyrambic* beat, &c. A compound *dithyrambic* word, Mr. Dacier observes, has sometimes its beauty and force. Some moderns call compositions which are in the taste of an ode, only not distinguished into strophes, and consisting of all kinds of verse indifferently, *dithyrambic* odes.

Dithyrambic poetry owes its birth to Greece, and the trans-

ports of wine. It favours strongly of its original; admitting of no rules, but the fallies of a fiery imagination. And yet art is not quite excluded; but delicately applied, to guide and restrain the *dithyrambic* impetuosity, and only indulge it in flights that are pleasing. In effect, what our poets say of the ode, is more true of the *dithyrambic* than of the ode, that its disorder is an effect of art.

DITHYRAMBUS, *Διθύραμβος*, in the *Ancient Poetry*, a hymn in honour of Bacchus, full of transport, and poetical rage.

The measure, which is what distinguishes this kind of poetry, is said to have been invented by *Dithyrambus*, a Thelian; but Pindar attributes it to the Corinthians; and the modern etymologists furnish us with another origin of the word.

In effect, the verse might be called thus from the god it was consecrated to, who himself was named *Dithyrambus*; either on account of his having been brought twice into the world, according to the fable of Semele and Jupiter, or by reason of his having triumphed twice; from *dis*, *twice*, and *triumph*, *trionphos*. Be this as it will, the ancients, we are told by Aristotle and Horace, gave the appellation *dithyrambus* to those verses wherein none of the common rules or measures were observed; much like those called by the French *vers libres*, by the Italians *versi sciolti*; and by the modern Greeks *politi*, a name they give to prose, which these verses resemble more than poetry.

We have now no remains of the *dithyrambi* of the ancient poets, so that we cannot say precisely what their measure was; all we know is, that it is very bold and irregular. The poets not only took the liberty to forge new words for the purpose, but they made double, and compound words, which contributed very much to the magnificence of the *dithyrambus*.

Horace has sometimes imitated them. Dacier, F. Commaire, and some of our modern writers, have composed Latin pieces of all kinds of verse indifferently, according as the subject and words presented themselves, without any order, or distribution into strophes, and call them *dithyrambi*. See *PINDARIC*.

DITONE, *DITONUM*, in *Music*, an interval comprehending two tones, a greater and a less. See *INTERVAL*, and *TOPE*.

The word is formed of *dis*, *twice*; and *tonos*, *tone*.

The ratio of the sounds that form the *ditone* is of 4 to 5; and that of the *semi-ditone*, of 5 to 6. F. PASTON makes the *ditone* the fourth kind of simple concords; others make it the fifth discord, dividing the *ditone* into eighteen equal parts, or commas, the nine on the acute side go to the greater tone. Salomon de Caux.

DITONIC, *DITONICUS*, in *Music*, according to Zarlino, is the pure and natural diatonicism, or the diatonic of Didymus; in which not one of the sounds it is in the least altered: such is the plain chant of the church. But the genus *diatonicum ditonum* of Ptolemy, which coincides with the *diatonic* of Pythagoras, and results from that division of a monochord bearing the name of Euclid's section of the canon, is expressed by $144 \times 1 = 1$. But these ancient systems have justly been laid aside, since the invention of a temperament, as being unfit for the execution of musical compositions in several parts. Smith's Harmon. p. 33.

DITONICUM *Diatonum*. See *GENUS*.

DITRIGLYPH, in *Architecture*, the space between two triglyphs. See *TRIGLYPH*.

DITRIHEDRIA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *dis*, *twice*, *tri*, *three*, and *hedra*, *a side or plane*. The bodies of this genus are spars composed of twice three planes, being formed of two trigonal pyramids joined base to base, without the intervention of any intermediate column. Of this genus there are five known species: 1. One with long and pointed pyramids, found in the mines of Cornwall, and some other parts of England: 2. One with long and broad pyramids, found loose in the fissures of the alabaster quarries of Blackenberg, in Germany. 3. One with short and broad pyramids, found in the mines of Rammelsberg. 4. One with extremely broad deformed pyramids, found in the alabaster quarries at Blackenberg, and sometimes in the mines of Goltzsch in Saxony. 5. One with short, but sharp-pointed pyramids, found very frequently in the mines of the Harz Forest, and sometimes on Mendip Hills with us. Hill's Fossils, p. 218.

DITTANDER, or *Pervinca-vera*, or *Pur Man's Pepper*, *Lepidium*, in *Botany*, a genus of the *tribus* *Primula* class. Its characters are these: the flower has four oval petals placed in form of a cross, and six awl-shaped stamens, two of which are shorter than the other; in the centre is situated a heart-shaped germen, which turns to

a spear-shaped seed-vessel with two cells, divided by an intermediate partition, containing oblong seeds. There are several species.

The leaves of the broad-leaved *dittander*, bruised and mixed with hog's lard, and applied as a cataplasm to the hips, flux the sciatica; when chewed, they cause a great flux of rheum; and by that means are said to help scrophulous humours of the throat. The women in Suffolk give them boiled in ale, to hasten the birth.

The *dittander* with a grana leaf, or iberis, is also commended for its virtues in sciaticas, when applied as the former; and hence it has been sometimes called the *sciatia-crafi*.

DITTANY, *white*, *Dittamnus*, in *Botany*, a genus of the *decandria monogynia* class. Its characters are these: the flower hath five petals, which are unequal, and ten stamens, which are as long as the petals. In the centre is situated a five-cornered germin, which afterward becomes a capsule, with five cells joining together, enclosing several roundish, hard, shining seeds. We have but one species, which is the white *dittany*, commonly called *fraxinella*.

There are three varieties of this plant: one with a pale red flower, striped with purple; another with a white flower, and one with shorter spikes of flowers; but as they have been observed to vary when propagated by seeds, they are to be esteemed only feminal varieties.

This is a very ornamental plant for gardens; and as it requires very little culture, deserves a place in all good gardens. It hath a perennial root, which strikes very deep into the ground.

The *fraxinella*, or white *dittany* of authors, is cultivated in gardens with us, and grows wild in France, Italy, and Germany. It generally grows about two feet high. The leaves much resemble those of the common ash-tree, whence it has its name; the flowers are produced in long spikes, and are of a whitish red, mixed with purple. The cortical part of the root is sometimes brought to us, dried and rolled up in the form of quills.

This root should be chosen plump and full, white within and without, little hardened with small fibres, and clean. It is alexipharmic, antelmintic, diuretic, and uterine, but now very rarely used.

DITTANY, *softest*. See *HOREHOUND*.

DITTANY of *Croci*. See *WILD MARJORAM*.

DITTO, in *Books of Accounts*, written contractedly *D^o*, signifies the same, viz. as the preceding article.

The word is corrupted from the Italian *ditto*, the said; as in our law-phrases "the said premises," meaning the same as were aforementioned.

DIVAL, in *Heraldry*, the herb NIGHT-SHADE, a plant with poisonous berries, looking like black cherries, used by such as blazon with flowers and herbs instead of colours and metals, for fable, or black. See *SABLE*.

DIVALIA, in *Antiquity*, a feast held among the ancient Romans on the twenty-fifth day of December, in honour of the goddess Angerona; whence it is also called *ANGERONIA*.

On the day of this feast, the pontifices performed sacrifice in the temple of Voluptus; or the goddess of joy and pleasure, who, some say, was the same with Angerona; and supposed to drive away all the sorrows and chagrins of life.

DIVAN, a council-chamber, or court, wherein justice is administered, in the eastern nations, particularly among the Turks.

Divan is an Arabic word, signifying the same with *synodus* in the Turkish dialect.

There are two sorts of *divans*, that of the grand signior called the council of state, which consists of seven of the principal officers of the empire; and that of the grand vizir, composed of six other vizirs, or counsellors of state, the chancellor and secretaries of state, for the distribution of justice.

The word is also used for a hall, in the private houses of the orientals. The custom of China does not allow the receiving of visits in the inner parts of the house, but only at the entry, in a *divan* contrived on purpose for ceremonies. Le Compte.

Travellers relate wonders of the silence and expedition of the *divans* of the East.

DIVAN-BEGHIS, the appellation of one of the ministers of state in Persia.

The *divan-beghis* is the superintendent of justice; his place is the last of the six ministers of the second rank, who are all under the atemadalet, or sixth minister.

To the tribunal of the *divan-beghis* appeals lie from sentences passed by the government. He has a fixed stipend, or appointment, of 50,000 crowns, that he may render justice *gratu*. All the sergeants, uthers, &c. of the court, are in the service of the *divan-beghis*. He takes cognizance of the criminal causes of the chams, gover-

nors, and other great lords of Persia, when accused of any fault, and receives appeals from the daruga.

There are *divan-beghis* not only at court, and in the capital, but also in the provinces, and other cities of the empire.

This officer is not confined by any other law or rule, in the administration of justice, but the Alcoran, which also he interprets at pleasure. He takes no cognizance of civil causes.

DIVER, in *Ornithology*, the English name of the *COLYMBA*, a genus of water birds; the characters of which are these: they have narrow, straight, and sharp bills; the upper mandible is the longest, with the edges of each bending in, the nostrils are linear, their heads are small, the tongue pointed, long, and serrated near the base, their wings short, their feet placed far backward on the body, and near the tail, which is short, consisting of twenty feathers, and their legs broad and flattened, their claws broad like the nails of one's fingers. They are called *colymbi*, and in English *divers*, from their great expertness in diving, and long continuance under water.

There are properly two subordinate genera of these birds; the one having the feet not webbed, but the toes loose, yet all widened by a membrane, and having no tail. Those of the other genus have webbed feet like the duck, and have tails.

Of each of these genera there are several species. See *TAB. IV. Birds*, N^o. 47, and articles *DON-CHICK*, *SEA-TURTLE*, *DOVE*, *LUMME*, and *FLOODEE*.

DIVER, *black*. See *SCOTTER*.

DIVER, *don*. See *DUN-DIVER*.

DIVERGENCY. For the point of *divergency* or *divergence* in *Optics*, see *VIRTUAL FOCUS*.

DIVERGENT, or **DIVERGING** *line*, in *Geometry*, are such whose distance is continually increasing.

Lines which converge one way, *diverge* the opposite way. **DIVERGENT**, or **DIVERGING**, in *Optics*, is particularly applied to rays, which, issuing from a radiant point, or having in their passage undergone a refraction, or reflection, do continually recede farther from each other.

In which sense the word is opposed to *convergent*, which implies the rays to approach each other; or to tend to a centre, where, being arrived, they intersect; and, if continued farther, become *diverging*.

Concave glasses render the rays *diverging*; and convex ones, *converging*.

Concave mirrors make the rays converge; and convex ones, *diverge*. See *FOCUS*.

It is demonstrated, in *Optics*, that as the diameter of a pretty large pupil does not exceed $\frac{1}{2}$ of a digit, *diverging* rays, flowing from a radiant point, will enter the pupil, parallel, to all intents and purposes, if the distance of the radiant from the eye be 40,000 feet. See *LIGHT*, and *VISION*.

DIVERGING hyperbola, is one whose legs turn their convexities towards one another, and run towards quite contrary ways.

DIVERSIFYING, in *Rhetoric*, is of infinite service to the orator; it is an accomplishment essential to his character, and may fitly be called the subject of all his tropes and figures. Vossius lays down six ways of *diversifying* a subject. 1. By enlarging on what was briefly mentioned before. 2. By a concise enumeration of what had been insisted on at length. 3. By adding something new to what is repeated. 4. By repeating only the principal heads of what had been said. 5. By transposing the words and periods. 6. By imitating them. Voss. Rhet. lib. v. p. 281, seq.

DIVERSION, in *Medicine*, the turning of the course or flux of humours from one part to another, by proper applications.

DIVERSION, in *War*, the act of attacking an enemy in one place, where he is weak, and unprovided, with design to make him call his forces from another place, where he was going to make an irruption, or is to be attacked with greater force.

The Romans had no way to drive Hannibal out of Italy, but to make a *diversion*, by attacking Carthage.

DIVERSITY. This differs from distinction in this, that the latter is the work of the mind; but the former is in things themselves, antecedent to the operation of the mind. For things that are several, are different; even though I do not conceive them. See *DISTINCTION*.

The *diversity*, or difference of things, therefore, arises from their essential attributes. See *IDENTITY*.

DIVERSITY, in *Painting*, consists in giving every part or figure in a picture its proper air and attitude. The skilful painter has the penetration to discern the character of nature, which vary in all men; whence the countenances and gestures of the persons he paints continually vary.

The word *diving* is derived from *N78* *Alia*, *Gol*: so that the *diver* is the *diver*, or *diver*, as Calvius renders it; or, such as own a *Gol*.

DIVING, the art, or act of descending under water, to considerable depths, and abiding there a competent time.

The uses of *diving* are very considerable, particularly in the fishing for pearls, corals, sponges, &c. See *PEARL-FISHING*.

There have been divers methods proposed, and engines contrived, to render the business of *diving* more safe and easy. The great point in all these is to furnish the *diver* with fresh air, without which, he must either make but a short stay, or perish.

Those who dive for sponges in the Mediterranean, help themselves by carrying down sponges dip in oil in their mouths. But conducting the small quantity of air that can be contained in the pores of a sponge, and how much that little will be contracted by the pressure of the incumbent air, such a supply cannot long subsist the *diver*. For it is found by experiment, that a gallon of air included in a bladder, and by a pipe reciprocally inspired and expired by the lungs, becomes unfit for respiration in little more than one minute of time. For though its elasticity be but little altered in passing the lungs, yet it loses its vivifying spirit, and is rendered effete.

In effect, a naked *diver*, Dr. Halley assures us, without a sponge, cannot remain above two minutes enclosed in water; nor much longer with one, without suffocating; nor without long practice, near so long; ordinarily persons beginning to be suffocated in about half a minute. Besides, if the depth be considerable, the pressure of the water in the vessels makes the eyes blood-shot, and frequently occasions a spitting of blood.

Hence, where there has been occasion to continue long at the bottom, some have contrived double flexible pipes, to circulate air down into a cavity enclosing the *diver*, at with armour, both to furnish air, and to bear off the pressure of the water, and give leave to his breast to dilate upon inspiration; the fresh air being forced down one of the pipes with bellows, and returning by the other of them, not unlike to an artery and vein.

But this method is impracticable when the depth surpasses three fathoms; the water embracing the bare limbs so closely, as to obstruct a circulation of the blood in them; and whilst pressing so strongly on all the junctures where the armour is made tight with leather, that if there be the least defect in any of them, the water rushes in, and instantly fills the whole engine, to the great danger of the *diver's* life.

DIVING-BELL, is a machine contrived to remedy all these inconveniences. In this the *diver* is safely conveyed to any reasonable depth, and may stay more or less time under the water, as the bell is greater or less.

It is most conveniently made in form of a truncated cone, the smallest base being closed, and the larger open. It is to be poised with lead, and so suspended, that it may sink full of air, with its open base downward, and as near as may be in a horizon parallel to the horizon, so as to close with the surface of the water all at once.

Under this coverle the *diver* sits, sinks down with the included air to the depth desired; and if the cavity of the vessel can contain a ton of water, a single man may remain a full hour, without much inconvenience, at the depth of five or six fathoms.

But the lower you go, still the more the included air contracts itself, according to the weight of the water that compresses it; so that at the depth of thirty-three feet the bell becomes half full of water; the pressure of the incumbent water being then equal to that of the atmosphere; and at all other depths, the space occupied by the compressed air in the upper part of the bell, will be to the under part of its capacity filled with water, as thirty-three feet to the depth of the surface of the water in the bell below the common surface thereof. And this condensed air, being taken in with the breath, soon insinuates itself into all the cavities of the body, and has no ill effect, provided the bell be permitted to descend so slowly as to allow time for that purpose.

One inconvenience that attends it, is found in the ears, within which there are cavities which open only outwards, and that by pores so small, as not to give admission even to the air itself, unless they be dilated and distended by a considerable force. Hence, on the first descent of the bell, a pressure begins to be felt on each ear, which, by degrees, grows painful, till the force overcoming the oblique, what contrivances these pores, yields to the pressure, and letting some condensed air slip in, presently eases the ear. The bell descending lower, the pain is renewed, and afterwards it is again eased in the same manner.

But the greatest inconvenience of this engine is, that the

water entering it, contracts the bulk of air into so small a compass, that it soon heats, and becomes unfit for respiration: so that there is a necessity for its being drawn up to recruit it; besides the uncomfortable abiding of the *diver*, who is almost covered with water.

To obviate the difficulties of the *diving-bell*, Dr. Halley, to whom we owe the preceding account, contrived some farther apparatus, who did not only to recruit and refresh the air from time to time, but also to keep the water wholly out of it at any depth; which he effected after the following manner.

His *diving-bell* (see *Tab. Hydraulica*, fig. 1.) was of wood, three feet wide at top, five feet at bottom, and eight feet high, containing about sixty three cubic feet in its concavity, coated externally with lead to heavy, that it would sink empty; a particular weight being distributed about its bottom *B*, to make it descend perpendicularly, and no otherwise. In the top was fixed a meniscus glass *D*, concave downwards, like a window, to let in light from above; with a cock, as at *B*, to let out the hot air; and a circular fast, as at *L.M.*, for the *diver* to sit on: and below, about a yard under the *bell*, was a flange furnished from it by three pipes, each charged with a hundred weight, to keep it steady, and for the *diver* to stand upon to do their business. The machine was fastened by the snail of a ship by a *gir*, which was secured by stays to the masts-head, and was directed by braces to carry it overboard clear of the side of the ship, and to bring it in again.

To supply air to this *bell* when under water, he had a couple of barrels, as *C*, holding thirty-six gallons each, cased with lead, to sit to sink empty, each having a bung-hole at bottom, to let in the air they descended, and let it out again as they were drawn up again. In the top of the barrels was another hole, to which was fixed a leather pipe, or hose, well prepared with bees wax and oil, long enough to hang below the bung-hole; being kept down by a weight appended. So that the air driven to the upper part of the barrel by the encroachment of the water, in the descent, could not escape up this pipe, unless the lower end were lifted up.

These air-barrels were fitted with tackle, to make them rise and fall alternately, like two buckets; being directed in their descent by lines fastened to the under edge of the *bell*, so that they came readily to the hand of a man placed on the stage to receive them; and who taking up the ends of the pipes as soon as they came above the surface of the water in the barrels, all the air included in the upper part thereof was blown forcibly into the *bell*; the water taking its place.

One barrel thus received and emptied upon a signal given, it was drawn up, and at the same time the other let down; by which alternate succession fresh air was furnished so plentifully, that the learned doctor himself was one of five, who were all together in nine or ten fathoms depth of water for above an hour and a half, without the least inconvenience; the whole cavity of the *bell* being perfectly dry.

All the precaution he observed was, to be let down gradually about twelve feet at a time, and then to stop, and drive out the water that had entered, by taking in three or four barrels of fresh air, before he descended further. And, being arrived at the depth intended, he let out as much of the hot air that had been breathed, as each barrel would replace with cold, by means of the cock *B*, at the top of the *bell*, through whose aperture, though very small, the air will rush with too much violence, as to make the surface of the sea boil.

Thus, he found any thing could be done that was required to be done underneath. And by taking off the stage, he could, for a space as wide as the circuit of the *bell*, lay the bottom of the sea far dry as not to be over-shoes therein. Besides, that by the glass-window so much light was transmitted, that, when the sea was clear, and especially when the sun shone, he could see perfectly well to write or read, much more to listen, or say hold of any thing under him that was to be taken up. And by the return of the air-barrel he often lent up orders written with an iron pen on a plate of lead, directing how he would be moved from place to place.

At other times, when the water was troubled and thick, it would be as dark as night below: but in such cases he was able to keep a candle burning in the *bell*.

Dr. Halley observes, that they were subject to one inconvenience in this *bell*; they felt at first a small pain in their ears, as if the end of a tobacco-pipe were thrust into them; but after a little while there was a small puff of air, with a little noise, and they were easy. This he supposes to be occasioned by the condensed air forcing up a valve leading from some cavity in the ear, full of common air; but when the condensed air pressed harder, it forced the valve to yield, and filled every cavity. On

of the *diver*, in order to prevent this pressure, stopped his ear with a pledge of paper; which was pulled in so far, that a surgeon could not extract it without great difficulty.

The same author intimates, that by an additional contrivance he has found it practicable for a *diver* to go out of the *bell* to a good distance from it: the air being conveyed to him in a continued stream by small flexible pipes, which serve him as a clue to direct him back again to the *bell*. For this purpose, one end of one of these pipes, kept open against the pressure of the sea, by a small spiral wire, and made tight without by painted leather, and sheep's guts drawn over it, being open, was fastened in the *bell*, as at P, to receive air, and the other end was fixed to a leaden cap on the man's head, reaching down below his shoulders, open at bottom, to serve him as a little *bell*, full of air, for him to breathe at his work, which would keep out the water from him, when at the level of the great *bell*, because of the same density as the air in the great *bell*. But when he floated down lower than the level of the great *bell*, he shut the cock F, to cut off the communication between the two *bell*s. Phil. Trans. abstr. vol. iv. part ii. p. 188, &c. vol. vi. p. 550, &c.

The air in this *bell* would serve him for a minute or two; and he might instantly change it, by raising himself above the great *bell*, and opening the cock F. The *diver* was furnished with a girdle of large leaden weights, and cloths of lead for the feet, which, with the weight of the leaden cap, kept him firm on the ground; he was also well clothed with thick flannels, which being first made wet, and then warmed in the *bell* by the heat of his body, kept off the chill of the cold water for a considerable time, when he was out of the *bell*.

Mr. Martin Triewald, F. R. S. and military architect to his Swedish majesty, contrived to construct a *diving-bell* on a smaller scale, and less expence, than that of Dr. Halley, and yet capable of answering the same intents and purposes. This *bell*, AB (fig. 2.) links with leaden weights DD, suspended from the bottom of it. It is made of copper, and tinned all over on the inside; three strong convex lenses GGG, defended by the copper-lids HHH, illuminate this *bell*. The iron plate E serves the *diver* to stand upon, when he is at work; this is suspended by chains FFF, at such a distance from the bottom of the *bell* that when he stands upright, his head is just above the water in the *bell*, where he has the advantage of air filter for respiration, than when he is much higher up; but as there is occasion for the *diver* to be wholly in the *bell*, and consequently his head in the upper part of it, Mr. Triewald has contrived, that, even there, after he has breathed the hot air as long as he well can, by means of a spiral copper tube *bc*, placed close to the inside of the *bell*, he may draw the cooler and fresher air from the lowermost parts; for which purpose a flexible leather-pipe, about two feet long, is fixed to the upper end of the tube at *b*; and to the other end of the pipe is fastened an ivory mouth-piece, for the *diver* to hold in his mouth, by which to respire the air from below. We shall only remark, that as air rendered effect by respiration is somewhat heavier than common air, it must naturally subside in the *bell*; but it may probably be restored by the agitation of the sea-water, and thus become fitter for respiration. See *Fixed Air*. Phil. Trans. abstr. vol. viii. p. 634. or Defaguliers's Experiments. Phil. vol. ii. p. 220, &c.

The famous Corn. Drebell had an expedient in some respects superior even to the *diving-bell*, if what is related of it be true. He contrived not only a vessel to be rowed under-water, but also a liquor to be carried in the vessel, which supplied the place of fresh air.

The vessel was made for king James I. carrying twelve rowers, besides the passengers. It was tried in the river Thames; and one of the persons in that submarine navigation, then living, told it one, from whom Mr. Boyle had the relation.

As to the liquor, Mr. Boyle assures us, he discovered by a physician, who married Drebell's daughter, that it was used from time to time, when the air in that submarine boat was clogged by the breath of the company, and rendered unfit for respiration: at which time, by unslopping the vessel full of this liquor, he could speedily restore to the troubled air such a proportion of vital parts, as would make it serve again a good while. The secret of this liquor Drebell would never disclose to above one person, who himself assured Mr. Boyle what it was. Phil. Trans. abstr. vol. viii. p. 634. or Defaguliers's Experiments. Phil. vol. ii. p. 220, &c.

We have had many projects of *diving* machines, and *diving* ships of various kinds, which have proved abortive.

Divine-bladder, a term used by Borelli for a machine,

which he contrived for *diving* under the water to great depths, with great facility, and prefers to the common *diving-bell*. The vesicles or bladder, as it is usually called, is to be of brass or of copper, and about two feet in diameter. This is to contain the *diver's* head, and is to be fixed to a goat's skin habit, exactly fitted to the shape of the body of the person. Within this vesicle there are pipes, by means of which a circulation of air is contrived; and the person carries an air-pump by his side, by means of which he may make himself heavier or lighter, as the fishes do, by contracting or dilating their air bladder: by this means, the objections all other *diving* machines are liable to are obviated, and particularly that of the air; the moisture by which it is clogged in respiration, and by which it is rendered unfit for the same use again, being here taken from it by its circulation through the pipes, to the sides of which it adheres, and leaves the air as free as before. Borelli Opera Posthuma.

DIVINITY, the quality, nature, and essence of God.

It is fallacy, that the ancients hold the notion of a *divinity* to be a political invention of the ancient legislators, to secure and enforce the observation of their laws; on the contrary, it is certain, the legislators made use of that opinion, which they found already impressed on the minds of the people.

The *heavenly divinities* may be reduced to three classes: the first *theological*, representing the *divine* nature under *divers* attributes: thus Jupiter denotes the absolute power of God, Juno his justice, &c.

The second class of *divinities* are *physical*: thus *Æolus* is that power in nature, whereby vapours and exhalations are collected to form winds, &c.

The last are *moral divinities*. Thus the Furies are only the secret reproaches and stings of conscience.

DIVINITY is also used in the same sense with *THEOLOGY*.

DIUICHU, in *Botany*, a name given by the people of Guinea to a species of plant, with which they use to tipen or break bolls, beating the leaves, and laying them on.

DIVISIBILITY, a passive power, or property in quantity, whereby it becomes separable into parts; either actually, or at least mentally.

The schoolmen define *divisibility*, *capacitas continuationis cum pluribus*; a capacity of being co-extended with several things: thus, a staff four feet long is *divisible*, because it may be co-extended with four feet, or forty eight inches, &c.

This the Peripatetics and Cartesianes universally hold an affection, or property of all matter, or body: the Cartesianes, as holding the essence of matter to consist in extension; for every part, or corpuscule of the body being extended, has parts including other parts, and consequently is *divisible*.

The Epicureans, again, hold *divisibility* to agree to every physical continuum, as, without parts adjacent to parts, there can be no continuity; and wherever there are parts to adjacent, there must be *divisibility*. But they deny, that this affection agrees to all bodies; for the primary corpuscules, or atoms, they hold perfectly indivisible, and indissoluble.

The principal argument they allege is, that, from the *divisibility* of all body, and of every assignable particle of body, even after any repeated number of divisions, it follows, that the smallest corpuscule is infinitely *divisible*, which with them is an absurdity. For a body can only be divided into such parts as it actually contains. But to suppose infinite parts in the smallest corpuscule, say they, is to suppose it infinitely extended: for infinite parts placed externally to each other, as the parts of bodies doubtless are, must make an infinite extension.

They add, that there is a great difference between the *divisibility* of physical, and mathematical quantities. For every mathematical quantity, or dimension, they grant, may be increased and diminished infinitely; but physical quantity, neither the one nor the other.

An artist, dividing a continued body, arrives at certain minute parts, beyond which he cannot go; these we may call *minima artis*. In like manner, nature, which may begin where art ends, will find bounds; which we may call *minima nature*; and God, whose power is infinite, beginning where nature ends, may subdivide the *minima nature*; but he will at length come at certain parts, to which there being no other parts contiguous, they cannot be taken away. These minute parts are *ATOMI*.

All we can say on this subject is, that on the one hand it is certain, every extended corpuscule must have two sides, and consequently is *divisible*; for, if it had not two sides, it were not extended; and if it had no extension, an assemblage of divers such corpuscules would not compose a body. And on the other hand, the infinite *divisibility* supposes an infinity of parts in the minutest corpuscule; whence it follows, that there is no body, how small soever,

every, but may furnish us many surfaces, or parts, as the whole globe of the earth can; nay, and infinitely more; which, to say no worse, is a strange paradox.

The infinite divisibility of mathematical quantity is thus proved, and illustrated by the mathematicians: suppose a line AD (Tab. II. Geometry, fig. 27.) perpendicular to BF; another as GH, at a small distance from A, also perpendicular to the same line, with the centres C, C', C'', &c. and distances CA, CA', &c. describe the circles cutting the line GH in the points $\gamma, \gamma', \gamma'',$ &c. Now, the greater the radius AC is, the less is the part γG ; but the radius may be augmented *in infinitum*, and therefore the part γG may be diminished in the same manner; and yet it can never be reduced to nothing; because the circle can never coincide with the right line BF. Consequently, the parts of any magnitude may be diminished *in infinitum*.

The chief objections against this doctrine are, that an infinite cannot be contained by a finite; and that it follows from a *divisibility in infinitum*, either that all bodies are equal, or that one infinite is greater than another. To which it is answered, that to an infinite may be attributed the properties of a finite and determined quantity; and who has ever proved, that there could not be an infinite number of parts infinitely small in a finite quantity; or that all infinities are equal? The contrary is demonstrated by mathematicians in innumerable instances. We are not here contending for the possibility of an actual division *in infinitum*: we only assert, that however small a body is, it may be still farther divided; which we imagine may be called a division *in infinitum*, because what has no limits, is called *infinite*.

All that is supposed, in strict geometry, concerning the *divisibility* of magnitude, amounts to no more, than that a given magnitude may be conceived to be divided into a number of parts, equal to any given or proposed number. It is true, that the number of parts, into which a given magnitude may be conceived to be divided, is not to be fixed or limited, because no given number is so great but a greater may be conceived and assigned; but there is not, therefore, any necessity of supposing the number of parts actually infinite; and if some have drawn very absurd consequences from such a supposition, yet geometry ought not to be loaded with them. Mac-Laurin's Fluxions, art. 290. See EXTENSION.

It is true, that there are no such things as parts infinitely small; yet the subtilty of the particles of several bodies is such, that they very much furrows our conception; and there are innumerable instances in nature of such parts actually separated from one another.

Mr. Boyle gives us several instances of this. He speaks of a silken thread 200 yards long, that weighed but two grains and a half. He measured leaf-gold, and found by weighing it, that fifty square inches weighed but one grain: if the length of an inch be divided into 200 parts, the eye may distinguish them all; therefore there are in one square inch 40000 visible parts; and in one grain of it there are 200000 of such parts; which visible parts no one will deny to be farther *divisible*.

Again, a whole ounce of silver may be gilt with eight grains of gold, which may be afterwards drawn into a wire thirteen thousand feet long.

In odoriferous bodies we can still perceive a greater subtilty of parts, and even such as are actually separated from one another: several bodies scarce lose any sensible part of their weight in a long time, and yet continually fill a very large space with odoriferous particles. The particles of LIGHT, if light consists of real particles, furnish another surprising instance of the minuteness of some parts of matter. A lighted candle placed on a plane will be visible two miles, and consequently fill a sphere, whose diameter is four miles, with luminous particles, before it has lost any sensible part of its weight. And as the force of any body is directly in proportion to its quantity of matter multiplied by its velocity; and since the velocity of the particles of light is demonstrated to be at least a million of times greater than the velocity of a cannon ball, it is plain, that if a million of these particles were round, and as big as a small grain of sand, we durst not more open our eyes to the light, than expose them to find that point-blank from a cannon.

By help of microscopes, such objects as would otherwise escape our sight, appear very large: there are some small animals scarce visible with the best microscopes; and yet these have all the parts necessary for life, as blood, and other liquors. How wonderful must the subtilty of the parts be, which make up such fluids! See ARITHMETICS.

Whence is deducible the following theorem:
Any particle of matter, how small soever, and any finite space, how large soever, being given; it is possible for that small find, or particle of matter, to be diffused through all that great space, and to fill it in such manner.

VOL. II. N^o 100.

net, as that there shall be no pore in it, whose diameter shall exceed any given line; as is demonstrated by Dr. Keil. *Introduct. ad Ver. Phys.*

DIVISION, the act of separating a whole into the parts it contains.

If the whole be composed of parts really distinct, called *integral parts*, the *division* made thereof is properly called *partition*; as when a house is divided into its apartments. If the whole be composed of parts, called *subdivisions*; that is, if the whole be only one common term, the subdivisions comprised in the extent whereof are the parts, the *division* thereof is what we properly call *division*: such is the *division* of a genus into its species, &c.

DIVISION, in *Algebra*, or *Spoken*, is performed by reducing the dividend and divisor into the form of a fraction; this fraction being the quotient.

Thus, if ab were to be divided by cd , it must be placed thus, $\frac{ab}{cd}$, and that fraction is the quotient; though others choose to write it thus, $c \overline{) ab}$, or $c \overline{) d \overline{) ab}}$, or $a \overline{) b \overline{) c \overline{) d}}$, which last mark $\overline{)}$ is the most common character for *division*.

To perform the work of *division* algebraically, these rules are to be observed: 1. When the dividend is equal to the divisor, the quotient is unity, and must be placed in the quotient, because every thing contains itself once.

2. When the quotient is expressed *fraction-wise* (as in simple *division*) if the same letters are found equally repeated in each member of the numerator, and denominator; cast away those letters, and the remainder is the quotient: thus, $\frac{a^2b}{a^2c} = \frac{b}{c}$, &c.

3. When there are any co-efficients, divide them as in common arithmetic, or divide them by any common measure, and to the quotients annex the quantities expressed by letters: thus, $\frac{360ab}{24b} = 15a$.

4. The general way of *division* of compound quantities, after ranging them according to the dimensions of one of their letters, is like the ordinary way in common arithmetic, respect being had to the rules of algebraic addition, subtraction, and multiplication; as also that the like signs give +, and unlike - in the quotient; taking care to divide every part of the dividend by its corresponding divisor (that is, that whole letters shew it of the same kind with the other), to prevent a fraction, which would otherwise arise: thus,

$$\begin{array}{r} a+b \overline{) aa+ab-cd+e \overline{) a-b}} \\ aa+ab \phantom{-cd+e \overline{) a-b}} \\ \hline 0 \phantom{-cd+e \overline{) a-b}} \\ -c+e \phantom{\overline{) a-b}} \\ -e+a \phantom{\overline{) a-b}} \\ \hline 0 \end{array}$$

That the same reason for like signs giving a positive and unlike a negative quotient, does hold in *division*, as in multiplication, is clear from considering the nature of *division* (which is only reliving the thing into its parts); consequently, since every dividend is nothing else but the product of the divisor and quotient multiplied by each other, the quotient must consist of such signs, which could produce the dividend; therefore, if the dividend be divided by a quantity, that has a minus sign with it, the quotient must be positive; if by a quantity having a dissimilar sign, the quotient must be negative. It may be a general rule in compound *division* in algebra, always to place such a letter in the quotient, as will, when multiplied into the divisor, produce the dividend; for that is always a rectangle under the divisor, and the quotient: as for example,

$$\begin{array}{r} 2x-16 \overline{) 2x^2-8x-124} \\ 2x^2-16x \\ \hline 8x-124 \\ 8x-128 \\ \hline 4x-64 \\ 4x-64 \\ \hline 0 \end{array}$$

In some cases the quotient will form an *infinite series*, and then it is usual to set down the last remainder with the divisor under it.

DIVISION, in *Arithmetic*, is the last of the four fundamental rules, being that whereby we find how often a less quantity is contained in a greater; and the overplus.

Division, in reality, is only a compendious method of subtraction; its effect being to take a less number from another greater as often as possible; that is, as oft as it is contained therein. There are, therefore, three num-

here concerned in division: 1. That given to be divided, called the *dividend*. 2. That whereby the dividend is to be divided, called the *divisor*. 3. That which expresses how often the divisor is contained in the dividend; or the number resulting from the *division* of the dividend by the divisor, called the *quotient*.

There are diverse ways of performing *division*, one called the *English*, another the *French*, another the *Italian*, another the *Spanish*, another the *German*, and another the *Indian* way, all equally just, as finding the quotient with the same certainty, and only differing in the manner of arranging, and disposing the numbers.

We have likewise *division* in integers; *division* in fractions; and *division* in species, or algebra.

Division is performed by seeking how often the divisor is contained in the dividend; and when the latter consists of a greater number of figures than the former, the dividend must be taken into parts, beginning from the left, and proceeding to the right, and seeking how often the divisor is found in each of these parts.

For example, it is required to divide 6759 by 3. I first seek how oft 3 is contained in 6, viz. twice, then how oft in 7, which is likewise twice, with one remaining. This 1, therefore, is joined to the next figure 5, which makes 15, and I seek how oft 3 is in 15; and lastly, how oft 3 in 9. All the numbers expressing how oft 3 is contained in each of those parts, I write down according to the order of the parts of the dividend, that is from left to right, and separate them from the dividend itself, by a line, thus.

Divisor. Dividend. Quotient.
3) 6759 (2253

It appears therefore, that 3 is contained 2253 times in 6759, or that 6759 being divided into 3 parts, each part will be 2253. If there be any remainder, that is, if the divisor repeated a certain number of times is not equal to the dividend, what remains is wrote over the divisor fraction-wise. Thus, if instead of 6759 the dividend were only 6758, the quotient will be the same as in the former case, except for the last figure 8; for 3 being only contained twice in 8, the last number in the quotient will be 2; and as twice three is only 6, there remains 2 of the dividend; which I write after the quotient, with the divisor underneath it, and a line to separate the two, thus:

3) 6758 (2252

If the divisor is a digit, the *division* may be easily performed without setting down any thing but the remainders. Again, if the divisor has cyphers in the first places towards the right-hand, these may be cut off, provided that an equal number of figures be cut off from the right of the dividend; and when the *division* is finished, we obtain the integral quotient; then to the remainder annex all the excluded figures of the dividend, and subjoin the whole divisor. Thus,

800) 367854 (459 integral quotient.

Rem. 654, and the fractional part of the quotient is $\frac{654}{800}$

Moreover, if the divisor is the product of two or more digits, which may be easily discovered, divide first by any one of these, and then divide the quotient by the other, and so on, the last quotient is that required; and for the fractional part, multiply the last remainder by the preceding divisor, and to the product add the preceding remainder; multiply this sum by the next preceding divisor, and so on, till you have got through all the divisors and remainders to the first. Thus, to divide 342589 by 126, divide by 3, 6, and 7, because $3 \times 6 \times 7 = 126$, the first quotient is 1142896, and the remainder 1; the second quotient is 190182, and the remainder 4; the last quotient is 2711, and the remainder 5, which multiplied by the preceding divisor 6, produces 30, to which the preceding remainder 4 being added, we have 34; this multiplied by the preceding or first divisor, produces 102, and the remainder 1 added, makes 103; the true remainder; and the fractional part of the quotient is $\frac{103}{126}$. For the *division* of concrete, or apud numbers, see REDUCTION.

Proof of DIVISION.

Division is proved by multiplying the quotient by the divisor, or the divisor by the quotient; and adding what remains of the *division*, if there be any thing. If the sum be found equal to the dividend, the operation is just, otherwise there is a mistake.

Division in Decimal Fractions. See DECIMAL.

Division, in Geometry, or geometrical *Division*, is also

called *application*; the design of which, when it is employed about the construction of plain problems, is this: viz. a rectangle being given, as also a right line; to find another right line, the rectangle contained under which, with the right line given, shall be equal to the rectangle first given. Such efficient or construction, is called the *application* of a given rectangle to a right line given; and the right line arising by such application, is called the *geometrical quotient*.

This is found by the rule of three, by saying, as the line given is to one side of the rectangle, so is the other side to the line sought.

Not unlike to which is Des Cartes's way of working *division* in lines, by scale and compass: thus, suppose ac ($=b$), were to be divided by ad ($=a$) (Tab. II. Geometry, fig. 28), make any angle at pleasure, and therein set off first ad ($=a$), the divisor, and then on the same leg ae ($=b$) the dividend, and join de , and to it through a , draw af parallel to de , which shall cut off af the quotient sought; for as $ad : ae :: ac : af$, that is, as the divisor is to unity :: b is to the dividend :: to the quotient: on which proportion depends all *division*.

Division of a word, in Grammar, is a discourse explaining the latitude, or comprehension of a word, the latitude, when the word is universal; as when the genus is divided into species, and differences; the comprehension, when the word is ambiguous, as *horus*, *lucy*, which sometimes denotes a constellation, sometimes a beast, and sometimes a mountain.

Division by Logarithms. See LOGARITHM.

Division, in Logic, is the separating any thing into diverse parts, or ideas. See DISTRIBUTION.

The schoolmen define it a discourse, explaining a thing by its parts; in which it approaches near to the nature of a definition, whose character is to define a thing by its parts.

Division, we have said, is a distribution of a whole, &c. But there are two sorts of wholes, as above expressed. The first is what consists of integral parts; as the human body, which contains diverse members.

The second is properly no other than an abstract idea common to more things than one, as the universal; or a compound idea comprehending the substance and its accidents, or at least most of its accidents.

The whole admits of a triple *division*. 1. When the genus, or kind, is divided by its species, or differences; as when substance is divided into body and spirit; or into extended, and thinking.

2. When any thing is divided into several classes, by opposite accidents; as when stars are divided into those which shine by their own light, and those that only reflect a borrowed light.

3. When the accidents themselves are divided according to the subjects in which they inhere; as when goods are divided into those of the body, the mind, and fortune.

The laws of *division* are, 1. That it be full and adequate, that is, that the members of the *division* entirely exhaust the whole thing divided; as when all numbers are divided into equal, and unequal.

2. That the members of the *division* be opposite; as equal, and unequal; corporeal, and not corporeal; extended, and thinking.

3. That one member of the *division* be not contained in another, in as the other may be affirmed of it; though, in other respects, it might be included without any fault in the *division*: thus extension, geometrically considered, may be divided into a line, surface, and solid; though the line be included in the surface, and the surface in the solid.

4. The *division* must not be made into too many, or too general parts. Lastly, the members, unless the subject require it, not to be too unequal; as if the universe were divided into heaven and earth.

Division of mathematical instruments. See GRADUATION, and MORAL Axi.

Division of a mile, divides a quality into its degrees. Philosophers, after the physicians, suppose eight degrees of every quality; hence when a quality is said to be in the eighth degree, it marks, that it can be no farther increased, or heightened.

Division, in Music, imports the dividing of the interval of an octave into a number of lesser intervals.

The 4th and 5th, each of them, divide or measure the octave perfectly, though differently. When the 5th is below, and serves as a basis to the 4th, the *division* is called *harmonic*; when the 4th is below, the *division* is called *arithmetic*.

Division by Nicot's Rule. See NEVER'S RULE.

Division, in Physics, or Physico-mathematical, is the separation of the parts of a quantity; whereby, what before was one, is now reduced into several. See CONTINUITY, and DISSOLUTION.

This *division* is effected by means of motion, without which there can be no separation of any continuum, or even coniguum.

This motion is performed diverse ways, by fraction, fission, fission, fission, resolution, dilution, maceration, dispersion, effusion, distillation, &c.

DIVISION OF POWERS. See POWERS.

DIVISION OF PROPERTY. See PROPORTION.

DIVISION, in Rhetoric, the arrangement of a discourse under several heads, to be spoken to separately. See DISPOSITION.

DIVISION, in Vulgar Fractum. See FRACTION.

DIVISIONS of an army, in the Military Art, the several brigades and squadrons into which it is canonized. See BATTALION.

DIVISIONS of a battalion, the several platoons into which it is divided in marching or firing, each of which is commanded by an officer. See BATTALION.

DIVISION, in the Sea-Language, the third part of a naval army, or fleet; or one of the squadrons thereof, distinguished by a particular flag or pendant, under the command of some flag-officer. See SQUADRON.

The white flag denotes the first squadron of France, the white and blue the second, and the third is characterized by the blue. In England, the first admiral, or the admiral of the fleet, displays the union flag at the main-top-mast-head; next follows the white flag with St. George's cross, and afterwards the blue. The private ships carry pendants of the same colour with their respective squadrons at the masts of their particular divisions; so that the last ship in the division of the blue squadron carries a blue pendant at her main-top-mast-head. Naval battles are usually ranged in three lines, according to their three divisions.

DIVISIONES, in Antiquity, certain presents of money, oil, bread, wine, or the like, appointed by will to be distributed annually among certain persons or companies, and sometimes to the people in general.

DIVISOR, the dividing-number, or that which shows how many parts the dividend is to be divided into.

DIVORCE, common. See COHABITATION.

DIVORCE, from divorce, *liberum viro,* a breach or dissolution of the bond of MARRIAGE.

In our law, *divorce* is of two kinds; the one total, a *vincula matrimonii*, which alone is properly *divorce*; the other partial, a *mensa et thoro*; a separation from bed and board.

The woman divorced a *vincula matrimonii*, receives all again that she brought with her; the other has a suitable, separate maintenance allowed her out of her husband's effects. See ALIMONY.

The first only happens through some essential impediment, as consanguinity or affinity within the degrees forbidden, precontract, impotency, &c. of which impediments the canon law allows fourteen, comprehended in these verses:

*Error, coactio, vetus, cognatio, crimen,
Cultus, disparitas, vis, verus, ligamen, banus,
Si sit officio, si forte error iniquus,
Si pariter et dupli causa profectus testis,
Raptus sit mulier, nec pariter coacta testis.*

In this kind of *divorce*, the marriage is declared null, as having been absolutely unlawful, *ab initio*, and the parties are separated *pro salute animarum*, and allowed to marry again; the issue of such marriage as is thus entirely dissolved, are bastards. *Divorce a mensa et thoro* dissolveth not the marriage, because it was just and lawful *ab initio*; but for some supervenient cause, it becomes improper or impossible for the parties to live together; as in the case of intolerable ill temper, or adultery, in either of the parties. However, *divorce a vinculo matrimonii*, for adultery, have of late years been frequently granted in England, by act of parliament.

Divorce is a spiritual judgment, and therefore is called in the spiritual courts. Under the old law, the woman divorced was so, by her husband's writing, as St. Jeron and Josephus testify, to this effect: *I prout, thou hereafter I will lay no claim to thee*; which was called a *bill of divorce*.

Divorce was allowed in great latitude both among the Pagans and Jews. At Rome, barrenness, age, disease, madness, and banishment, were the ordinary causes of *divorce*. Spurius Carvilius, between two and four years after the building of Rome, under the consulship of M. Attilius, and P. Valerius, was the first who put away his wife, because she was barren; though Plutarch, in his Roman Questions, maintains, that Domitian was the first who permitted *divorce*.

Justinian afterwards added impotency, a vow of chastity, and the profession of a monastic life, as valid reasons of *divorce*.

The Roman lawyers distinguish between *repulium* and *avertium*; making the former to be the breaking of a

contract or espousal, and the latter separation after matrimony. Romulus enacted a severe law, which suffered not the wife to leave her husband, but gave the man the liberty of turning off his wife, either upon poisoning her children, counterfeiting his private keys, or for the crime of adultery; but if the husband on any other occasion put her away, he ordered one moiety of his estate for the wife, and the other to the goddess Ceres; besides an allotment to the gods of the earth. Put in Rom. However, in later times, the women, as well as the men, might sue a *divorce*. Juvenal, Sat. iii. Marital, lib. x. Ep. 47.

The common way of *divorcing* was by sending a bill to the woman containing the reasons of separation, and the tender of all her goods which she brought with her; and this was called *repulium mulieris*; or else it was performed in her presence, and before seven witnesses, and accompanied with the formalities of tearing the writings, refunding the portion, taking away the keys, and turning the woman out of doors.

The Grecian laws concerning *divorces* were different: the Greeks allowed *divorce* to any man that was afraid of having too many children. The Spartans seldom *divorced* their wives; and it was extremely scandalous for a woman to depart from her husband. The Athenians allowed *divorce* on very small grounds, by a bill, containing the reason of the *divorce*, and approved, if the party appealed, by the chief magistrate; and women also were allowed to leave their husbands on just occasions. Persons *divorcing* their wives were obliged to return their portions, otherwise, the Athenian laws obliged them to pay nine oboli a month for alimony. The terms expressing the separation of men and women from each other were different: the men were said *anastereio*, or *anastereio*, to signify their *avert*, but wives *anastereio*, to leave their husbands. Pott. Arch. Græc. vol. ii. book iv. cap. 12.

Among the Jews, besides incontinence and adultery, ugliness, old age, or ill humour in a wife, were sufficient reasons for giving her a bill of *divorce*. Nay, even the man's own pleasure, or his repenting of his match, were admitted as good reasons. Seldæus de Uxore Heb. lib. iii. cap. 17.

It is generally held, that Jesus Christ allowed *divorce* in the case of adultery. But some take this for a mistake; and maintain, that *divorce* is no where permitted in the New Testament for adultery; but only a separation. See Matt. xix. 9. Mark x. 11. Paul i Cor. vii. 27. See also the council of Florence, at the end, after the questions proposed to the Greeks. Terrul. de Monog. cap. 9. & 10. Augustin. de Bono Conjugio, & de Adult. Conjug. See ADULTERY.

Pope Innocent I. in his decretal to Lupatus, declares such a contract a new marriage after *divorce*, adulteries; as well as the persons with whom they marry. The occasion of this decree was, that such marriages were then allowed of by the Roman laws. There is an exception, however, in case of marriage between two heathens, which the decrees allow to be dissolved after the conversion of one of the parties. And St. Paul lays the same, i Cor. vii. 15. Yet even in this case, 1. The marriage is not immediately dissolved by the conversion of one of the parties, but they may still live together, and even on some occasions they ought to do so. Nor is it even dissolved by the separation of the infidel party: for if she be afterwards converted, he is obliged to take back his wife. But the marriage is totally dissolved by a second marriage of the converted party with another person.

2. Though the party converted to the faith may, the minute of his conversion, legally separate himself, and contract with another, a liberty the Christian law allows him, as in justice he is not deemed to owe any thing to an infidel; yet charity frequently forbids such *divorce*, and separation: as, e. gr. if the infidel consent to live with him, and do not molest him in his religion; if his faith be not at all in danger; if there be any hopes of converting her, or of gaining the children; if the separation would prove a scandal to the heathens, and render Christianity odious, &c. See St. Paul i Cor. vii. 15. 16.

The fourth council of Toledo decrees, that in a country where Christianity is the prevailing religion, the infidel party must be converted to become Christian; which if she refuse, the marriage must be dissolved. The council of Trent prohibits *divorce* on any occasion whatever. The papal dispensations, however, are a false for this instance of rigour.

In England, *divorce* can only be had by consent of parliament. Milton has an exact treatise of the doctrine and discipline of *divorce*, where he maintains, that *divorce* ought to be permitted for a mere incompatibility of humours.

DIURETICS, *diuretica*, that separation which is made of the urine by the kidney.

The word is formed from *diu*, through, and *qua*, I make water.

DIURETICS, in *Medicine*, are such remedies as provoke or promote the discharge of urine.

Such is water drunk plentifully, white wine drunk in a morning, alkali salts of all kinds; sea-salt, sal gemmae, nitre, brax, alum, tartar, sal ammoniac, whey, four milk, lemon juice, &c.

Aqueous liquors are generally diuretic, especially if mixed with salt, and drank cold. Fermented liquors are the least diuretic of all; and the less so, as they are the faster. Sharp, thin, four wines, Rheum, &c. as also acid spirits of vinegar, oil, sulphur, alum, vitriol, &c. asparagus, bitter almonds, smallage, eryngium, cupatimon, salafra, &c. are all diuretic.

DIURETICUS *sal.* See *SAL DIURETICUS*.

DIURNAL, from *diu*, day, in *Astronomy*, something relating to the day; in opposition to nocturnal, which regards the night.

DIURNAL *arcus*. See *ARCUS*.

DIURNAL *circulus*. See *CIRCULUS DIURNALIS*.

DIURNAL *motus* of a planet, is so many degrees and minutes, &c. as any planet moves in twenty-four hours. The **DIURNAL** *motus* of the earth, is its rotation round its axis, the space whereof constitutes the natural day.

The reality of the diurnal rotation of the earth is now past all dispute.

DIURNAL is also used in speaking of what belongs to the nycthemeron, or natural day of twenty-four hours. In which sense it stands opposed to annual, menstrual, &c. The diurnal phenomena of the heavenly bodies are solved from the diurnal revolution of the earth; that is from the revolution of the earth round its own axis in twenty-four hours. To illustrate this: suppose the circle PHTH (*Tab. Aëreæ*, *cap. 12.*) to denote the earth; C the centre of the earth, through which its axis is conceived to pass, around which a diurnal revolution is performed; P denotes any place in the earth; the line EW the visible horizon of the place; E the east point of the said horizon, W the west; the circle abdefg, the circumference of the heavens; the circle S, the sun in the heavens; the semicircle PRP, the enlightened hemisphere of the earth; or that half of it opposite to the sun; and lastly, the semicircle PHT, the darkened hemisphere of the earth.

Now, the earth supposed in this situation, and moving round its axis towards the sun; it is evident, the place P of the earth will then just begin to be enlightened by the sun; and to the sun will appear there to be just rising, or ascending the horizon at E the east point of it. The earth being moved round its own axis, so that the place P of the earth, which before was under the point a in the heavens, is now under the point e; it is evident, the horizon of the said place P will be now so situated, as that the sun will appear to a spectator at P, considerably ascended above E, the east end of the horizon. And while, by the revolution of the earth round its axis, the place P passes from under the point e in the heavens, to the point a, the horizon of the place P will continually sink lower and lower in respect of the sun, and to the sun will appear to ascend higher and higher, till P is come under e, where the sun will appear in its greatest height above the horizon for that day; and so it will be noon, or mid-day, at the place P. The earth moving on, as the place P passes from under e to d, the west point of its horizon will ascend higher and higher, and to the sun will appear more and more to descend, as is represented by the horizon at the point of the earth under d. The place P being carried by the diurnal revolution of the earth from under a to under e, the sun will then appear just in W, the west point of the horizon, and so will appear to be just setting. The place P being come under f, it will be then midnight there. Lastly, the place P being come round again under a, it will be then sun-rising again. The same holds good as to any other of the celestial lights, and the earth, as is obvious from the figure: the circle representing the sun being taken to denote any other star, planet, &c.

It remains to observe, that whereas, by the diurnal revolution of the earth, all the several celestial lights seem to move in the heavens from east to west, hence this seeming diurnal motion of the celestial lights is called their common motion, as being common to all of them. Besides, which, all the celestial lights, except the sun, have a proper motion from which arise their proper phenomena; as for the proper phenomena of the sun, they likewise seem to arise from the proper motion of the sun; but they are really produced by another motion, which the earth has, and whereby it moves round the sun once every year, whence it is called the annual motion of the earth.

DIURNARY, **DIURNARIUS**, an officer in the Greek em-

pire, who wrote down, in a book for that purpose, whatever the prince did, ordered, regulated, &c. every day.

DIURNITY, the long continuance or duration of any being.

DIVUS, **DIVA**, in *Antiquity*, appellations given to men and women who had been deified, or placed in the number of the gods.

Hence it is, that on medals struck for the consecration of an emperor or empress, they give them the title of *Divus*, or *Diva*. For example: **DIVUS JULIUS**. **DIVO ANTONINO PIO**. **DIVO PIO**. **DIVO CLAUDIO**. **DIVA FAUSTINA AUG.** &c.

DIZOSTOS, in *Botany*, a name given by some of the old Greek writers to the *opuntia*, or knobby-rooted spurge: it is so called, because of its having usually two or three slender and rush-like stalks, growing up from the roots, which seem as if they were fit to be used as cords or bandages. See *APICOR*.

DIZZINESS, in *Medicine*. See *VERTIGO*.

DO, in the *Italian Style*, is a syllable used instead of *at*, being supposed more resonant and musical than *at*.

Do bene—To do bene, *facite legem*, is the same as *to make law*, anno 23 Hen. VI. cap. 11. See *MAKE*.

DOB-CHICK, or **DOPATER**, in *Ornithology*, the common English name of a small water-fowl, the least of all the divers-kind, and known among authors by the name of *cygnus minor*; and called by Linnaeus *cygnus arcticus*. It seldom exceeds five ounces in weight, and has a short beak, not more than a finger's breadth long, large at the base, but tapering to a point at the end; its eyes are large, and it is covered with a very thick downy plumage; it is of a very deep blackish brown on the back, and very white on the belly; its wings are very small, and it has no tail.

This bird is of such a structure, that it moves much more easily under water, than on its surface, or aloft. He raises himself from the water with great difficulty; but when he is got up to the air, he can then continue his flight for a long time. He forms his nests by the water, near the banks, with a large quantity of vegetables, the fermentation of which, occasioned by the warmth of the bird, hatches the eggs, though the water rises through the nest, and keeps them wet. Phil. Trans. N^o 206. p. 290.

DOBULA, in *Ichthyology*, a name given by Gesner, and other writers, to the chub. It has been called *capio* and *cephalus* by the moderns, and *junius* by the ancients; but it requires no generic name, being properly only a species of the cyprinus. See *CEPHALUS* and *CYPRINUS*.

DORULA is also used for a fresh-water fish, of the leuciscus, or dace kind, but is of a larger and thinner shape, and a much better tasted fish. It is caught in the fresh waters of Germany about Hamburg, and in many other places. Schonfeldt, Hill. Pis.

DOCETÆ, from *doctus*, to appear, in *Ecclesiastical History*, the followers of Julius Cæsar, one of the VALERIANIAN sect, towards the close of the second century, who revived a notion that had been adopted by a branch of the Gnostics, against whom St. John, Ignatius, and Polycarp, had asserted the truth of the incarnation. They believed and taught, as their name imports, that the actions and sufferings of Jesus Christ were not in reality, but only in appearance.

DOCIMASIA, *Docimasia*, from *δοκιμαζω*, I try, in *Antiquity*, a custom among the *Siberians*, by which every man, before he was admitted to a public employment, was obliged to give an account of himself and his past life, before certain judges in the forum; for if any man had lived a vicious and scandalous life, he was thought unworthy of the magistracy office. Nor was this thought enough; for in the first ordinary assembly after their election, they were a second time brought to the test; when, if any thing scandalous was found against them, they were deprived of their honour. Poth. Archæol. Græc. lib. ii. cap. 11. tom. i. p. 73.

DOCIMASTICAL *experimentum*. See *ASPERITICO*.

DOCIMENUM *marmor*, a name given by the ancients to a species of marble, of a bright and clear white, much used in the large sumptuous buildings, as temples and the like. It had its name from Docimæna, a city of Phrygia, afterwards called Synus, near which it was dug, and from whence it was sent to Rome. It was accounted little inferior to the Parian in colour, but not capable of so elegant a polish: whence it was less used by the statuary, or in other smaller works. The emperor Adrian is said to have used this marble in building the temple of Jupiter, and many other of the great works of the Romans are of it.

DOCK, *Rumex*, *Lunatum*, in *Botany*, a genus of the *lentaculia trigyna* class. Its characters are these: the calament of the flower is permanent; the flower has three

three petals, which are larger than the emplacements to which they are very like. It hath its short hair-like stamina, terminated by erect thin filaments, and a three-cornered stigma, supporting three hair-like reduced styles, thrusting out of the clefts of the petals, crowned by large jagged filaments, the germens situated becomes a three-cornered frond, included in the petals of the flowers. Linnaeus reckons twenty-eight and Miller sixteen species.

The great water-dock, or *variegated* *variegata* of Linnaeus, has been long famous in medicine. The roots of the common wild dock are nearly of the same quality, and equally disperse their astringent matter, both in the stalk, and by striking an inkly blackness with solution of chalybeate water. Minutius was a disciple De Britannica Antiquorum Herbar. The endorsement to prove that its name *Hydrocotyle* was not derived from that of our island, but from Teutonic words, expressing the power of fattening loose teeth, or of curing the disease which makes them loose; and later experience has shown, that it is a medicine of considerable efficacy against putrid pterygia, gum, and an internal antiscorbutic. The roots are principally used, and are said to be of great service in the jaundice, in the herpes, and erysipelas, and in disposing inveterate ulcers to heal. It is also said to be a remedy in quinsies.

It has been chiefly used in medicated wines and small ale, with the addition of some spicy condiments, and sometimes of other antiscorbutic plants, as feuray-grass, black-bean, brack-radish, &c.

The *Indian evening* *Chelidonium*, *renouveau* of Linnaeus, or sharp-pointed-leaved dock, is as eminent as an antiscorbutic, and a cleanser of the blood. It is supposed to have an aperient as well as an astringent virtue, and is recommended in habitual colic, and obstructions of the viscera. A decoction of half an ounce, or an ounce, of the fresh roots, or of a dram or two of the dry roots, is commonly directed for a dose. It is also used externally in fumigations and ointments against the itch, and other cutaneous humors.

The *cock's*, as well as the *hen's* *anemone*, have been classed by Linnaeus under this genus.

DOCK, in the *Manner*, is used for a large cask of leather, as long as the end of a horse's tail, which serves it for a cover. The French call the dock *traverse*. It is made fall by straps to the crupper, and has leathern thongs that pass between his thighs, and along the flanks to the saddle-traps, in order to keep the tail tight, and to prevent its whirling about.

DOCK, among *Physicians*, is used for the fleshy part of a horse's chin, between the middle and the hunket.

DOCK, *DOCKING*, in *Law*, is a means or expedient for cutting off an estate till lands, or tenements, by means of a common recovery, that the owner may be enabled to sell, give, or bequeath the same.

DOCK, probably from *dog*, *receptaculum*, of *dog*, *reservoir*, in the *Sea-Langage*, is a pit, pond, or creek, by the side of an harbour, made convenient to work in, in order to build or repair ships.

This is of two sorts: a *dry dock*, where the water is kept out by great flood-gates, till the ship is built, or repaired; but afterwards can be easily let into it again to float, and launch her.

A *wet dock* is any place, in the quays, where a ship may be haled in, to *do* dock herself, or sink herself a place to lie in, and where she can be cleaned only during the recess of the tide.

DOCK-YARDS, are magazines of all sorts of naval stores, and timber for ship-building; the royal dock-yards in England, are these at Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Sheerness. In time of peace, ships of war are laid up in these docks, those of the first rate mostly at Chatham, where, and at other yards, they receive, from time to time, such repairs as are necessary. These yards are generally supplied from the northern crowns, with hemp, pitch, tar, resin, canvas, oak-plank, and several other species. But as for masts, particularly those of the largest size, they have been usually brought from New England.

The principal dock-yard is governed by a commissioner, resident at the port, who superintends all the matters of the officers, artificers, and labourers, employed in the dock-yard, and customs. He also contrains these persons, examines the accounts, contracts and draws bills on the navy-office to supply the deficiency of stores, and regulates whatever belongs to the yard, maintaining due order in the respective offices.

DOCKET sometimes denotes a little bill tied to wares or goods, and directed to the person and place they are to be sent to.

DOCKET, or *DOCKET*, in *Law*, is a brief in writing, on a small piece of paper, or parchment, containing the purport and effect of a larger writing. The rules of judgment. II. No. 101.

ment are *doctored*, when they are brought into the court of common-pleas, and entered on the docket of that term: so that by searching these *doctors*, any judgment may be found, if the attorney's name is known. Doctors in chancery are also *doctored*.

DOCTOR, a person who has passed all the degrees of a faculty, and is empowered to teach, or practise the same. The title of *doctor* was first created towards the middle of the twelfth century, to succeed to that of *maître*, which was become too common and familiar.

The establishment of the *doctors*, such as now in use amongst us, is ordinarily attributed to Innocent, who himself drew up the formulary. The first ceremony of this kind was performed in Bologna, in the person of Bulgensis, who began to preach the Roman law, and on that occasion was solemnly promoted to the *doctorate*, &c. in the hall of his university. But the custom was soon transferred from the faculty of law to that of theology; the first instance whereof was given in the university of Paris, where Fern. Lombard, and Gilbert de la Porree, the two chief divines of their days, were created *doctors* in theology, *facti theologie doctores*.

Specimen takes the title of *doctor* not to have commenced till after the publication of Lombard's sentences, about the year 1140, and *specimen*, this fact is explained that work to these scholars, were the first that had an application of *doctores*.

Oxford, so much higher, and held fast to have been the first done at Cambridge, and John de Beverley, or Oxeney, which latter died in the year 1211. But Specimen will not allow *doctor* to have been the name of any title or degree in England, till the reign of king John, about the year 1207.

To pass *doctor* in *divinity* at Oxford, it is necessary the candidate have been four years bachelor of divinity. For *doctor* of *divinity*, he must have been seven years in the university to commence bachelor of law five years after which he may be admitted *doctor* of law. *Doctor* in three years after taking the degree of master of arts, he may take the degree of bachelor in law, and in four years more, that of LL. D. which law included, and time are likewise required to pass the degree of *doctor* in *physic*.

At Cambridge, to take the degree of *doctor* in *divinity*, it is required the candidate have been seven years bachelor of divinity. Though in several of the colleges, the ranking of the bachelor of divinity's degree is dispensed with, and they may put on *per se* *doctores*. To commence *doctor* of law, the candidate must have been five years bachelor of law, or seven years master of arts. To pass *doctor* in *physic*, he must have been bachelor in *physic* five years, or seven years master of arts.

A *doctor* of the civil law may receive episcopal jurisdiction, though a layman, stat. 21 Hen. III. cap. 17, sect. 4.

Doctor of the law was a title of honour or dignity among the Jews.

The Jews, it is certain, had *doctors* long before Jesus Christ. The instructors, if we may so say, of this order, was performed by putting a key, into a male-book in their hands, which it was some authors imagine, Salomon had in view, Luke vi. 49, where speaking of the *doctors* of the law, he says, *Non sunt per doctores*, *doctores* of the law, for you have taken away the key of knowledge, and entered not in yourselves, and thus they were entering, and hindering.

The Greek text of St. Luke calls them *magistri*, and the Vulgate *scribae*, agreeably to which, our English translators call them *lawyers*. But the French version of *doctores* is to be taken the most accurate. In effect, the *magistri*, *scribae*, in only used in St. Luke, and St. Paul, 1 Tim. vi. 13. And *magistri* in St. Matthew xix. 16, is rendered by the Vulgate, *doctores*, though the English version still retains the word *lawyer*.

It is, I believe, *doctores* are also found in this otherwise call *magistri*.

Doctores of the church, a title given to certain of the fathers whose doctrine and opinion have been the most generally followed and authorized.

We usually reckon four *doctores* of the Greek church, and three of the Latin. The first are St. Athanasius, St. Basil, St. Gregory Nazianzen, and St. Chrysostom. The latter are St. Jerome, St. Augustine, and Gregory the Great.

In the Roman hierarchy there is a particular office for the *doctors*. It only differs from that of the *magisters*, by the addition of the *Magister*, and the *doctores*.

Doctores is also an appellation assigned to *doctores* of the sciences, entering wherein the name of such as the schools named for their masters, confers.

That Alexander Hale, is called the *father* of *Doctors*, and the *foundation* of *doctores* in *Physic*, Thomas Aquinas is called the *father* of *doctores* in *Law*. 2 M. 101.

venture, the *Scripture Doctor*; John Duns Scotus, the *Sacile Doctor*; Raymond Lully, the *Illuminatus Doctor*; Roger Bacon, the *Admirable Doctor*, &c.

DOCTOR, *doctores*, in the Greek Church, is a particular officer, appointed to interpret part of the Scriptures. He who interprets the Gospel is called *Doctor of the Gospel*; he who interprets St. Paul's Epistles, *Doctor of the Epistles*; he who interprets the Psalms, *Doctor of the Psalter*.

DOCTOR'S CHAIR. See *COLLEGE OF CIVILIANS*.

DOCTRINE, from *doctus*, I teach, denotes in general any thing that is taught, as a matter either of faith or practice; and the term has accordingly been applied to a variety of opinions, that have been adopted and inculcated in philosophy, religion, &c. There are certain *doctrines* respecting the political constitution of Great Britain, the asserting and publishing of which are made illegal by statute. Thus, if any person maliciously or advisedly asserts, that both or either of the houses of parliament have any legislative authority without the king, such person shall incur all the penalties of a praemunire. 12 Car. II. cap. 1. Also if a person affirm and maintain, by writing or printing, that the king and parliament have no right to direct the succession of the crown, he is guilty of high treason; and if he maintains the same doctrine by teaching, or advised speaking, he incurs a praemunire. 13 Eliz. cap. 1. 6 Anne, cap. 7. There are also other doctrines of a religious nature, which it is unlawful publicly to maintain and preach. See **BLASPHEMY**, **COMMON PRIMER**, **HERESY**, **TRINITY**, &c.

DOCTRINE, *doctrina*, *doctores*, &c. See **FATHERS**.

DOCUMENT, in Law, some written monument produced in proof of any fact asserted, especially an instrument.

DODARTIA, in Botany, a genus of the *diapensiaceae* class. In characters are these: the empanment is cut into five parts at top; the flower hath one petal, and two upper lip twice as long as the lower. It has four stamina, two of which are shorter than the others; in the centre is situated a round germ, which afterwards becomes a globular capsule with two cells, filled with small seeds. There are two species, natives of the East. James says there are no medical virtues attributed to this plant.

DODDER, *Cuscuta*. In the Linnaean system of Botany, this makes a distinct genus of plants, of the *terrestrial* class, the characters of which are these: the calyx is a one-celled perianthium, in form of a cup, fleshy at the base, and divided slightly into four obtuse segments at the rim. The flower is composed of only one petal, of an oval figure, a little longer than the cup, and divided slightly into four obtuse segments at the edge. The stamina are four pointed filaments, of the length of the cup; the anthers are roundish, the germ of the pistil is roundish; the styles are two in number, and are erect, and short; the stigmata are simple; the fruit is fleshy, and roundish, and contains two cells splitting open horizontally; the seeds are two from each flower.

This is a plant that differs from all others, in having no leaves, but consisting of a number of long, slender, red threads, or filaments, by which it takes hold, and twists about the plants that are near it, sucking its nourishment from them. It has several monopetalous flowers, divided generally into four short and narrow segments, to which succeed little round seed-vessels, containing each four small seeds. It grows frequently upon beards and common, on furze and nettles; as also in the fields upon flax and rye, doing great damage, and almost choking them; whence it is called by the country-people hell-weed, and devil's guts.

The *affusa* grows indifferently on all kinds of herbs; and, of consequence, the kinds thereof are infinite; to which writers usually attribute the particular virtues of the plants they grow on.

The most known of these plants, and those most used in medicine, are such as grow on thyme; which are the proper *epithyma*, and those on flax. There are two kinds in the shop; the one from Venice, the other from Candia; they have both an aromatic taste, but that of Venice has the strongest.

Dodder of thyme has been accounted opening and cleansing; good to purge melancholy and bilious humours, to open obstructions in the liver and spleen, good for the jaundice, and serviceable against the itch. But in this country it is an entire stranger to practice; though the remarkable facility of its taste seems to promise some considerable medicinal power.

DODECAGON, in Natural History, a name by which Linkius, and some other authors, have called a kind of asphyxius, or branched blaspit, which has twelve rays, first parting from the body, and each of these finally divided into many others.

DODECADICTYLON, in Anatomy, a name given by some of the old authors, to the gut called the twelve-

finger, from its being anciently supposed to be about twelve finger-breadth long.

DODECAGON, from *do-deca*, twelve, and *gonia*, angle, a regular polygon, or figure, with twelve equal sides and angles.

Dials are sometimes drawn on all the sides of a *dodecahedron*. In Particulation, a place surrounded with twelve bastions is called a *dodecahedron*; such is Palma Nova in Friuli, &c.

DODECAGYNIA, from *do-deca*, twelve, and *gynia*, female, a wife, in History, an order of plants, comprehending such as have twelve styles. See **TAB. II. of Botany**.

DODECAHEDRON, from *do-deca*, twelve, and *hedron*, feet, in Geometry, one of the regular bodies, comprehended under twelve equal sides; each whereof is a pentagon.

Or, a *dodecahedron* may be conceived to consist of twelve quinquangular pyramids, whose vertices, or tops, meet in the centre of a sphere conceived to circumscribe the solid; consequently they have their bases and altitudes equal.

And the solidity of the **DODECAHEDRON**. Find that of one of the pyramids, and multiply it by the number of bases, viz. 12; the product is the solidity of the whole body. Or its solidity is found by multiplying the base into 1/2 of its distance from the centre, twelve times; and to find this distance, take the distance of two parallel faces; the half is the height.

The diameter of the sphere being given, the side of the *dodecahedron* is found by this theorem: the square of the diameter of the sphere is equal to the rectangle under the aggregate of the sides of a *dodecahedron*, and hexahedron inscribed in the same, and triple the side of the *dodecahedron*. Thus, if the diameter of the sphere be 1, the side of the *dodecahedron* inscribed will be $\sqrt{3-4\sqrt{2}}$ = 24; consequently, that is to this as 2 to $\sqrt{1-4\sqrt{2}}$, and the square of that, to the square of this, as 6 to $3-4\sqrt{2}$. Therefore the diameter of the sphere is incommensurable to the side of an inscribed *dodecahedron*, both in itself, and its power.

DODECANDRIA, in Botany, the eleventh class of plants, which have hermaphrodite flowers, with twelve, or from twelve to nineteen inclusive, Stamina, or male parts in each. See **TAB. of Botany**, **Class 11**.

The word is formed of *do-deca*, twelve, and *andria*, male. This class comprehends five orders, viz. the *monogynia*, *diogynia*, *trigynia*, *polygynia*, and *dicarpya*.

Of this class of plants are the *astereaceae*, *agrimonia*, &c.

DODECATEMORY, from *do-deca*, twelve, and *temora*, parts, the twelfth part of a circle.

The term is chiefly applied to the twelve houses, or parts of the zodiac of the primus mobile; to distinguish them from the twelve signs.

DODECATEMORY is also a denomination some authors give to each of the twelve signs of the zodiac, because they contain a twelfth part of the zodiac's aspect.

DODECATHÉON, in Botany, a genus of plants of the *pentandria monogyna* class, with a wheel-shaped reflex flower, the stamina resting on the tubular base, and the fruit an oblong capsule, containing a single cell. There is one species.

DODO, in Ornithology, the name of a bird, called also by some *gallus eximius*, by others *gallus palmarum peregrinus*, and by Bonnus *draco*. It is a very singular bird, somewhat larger than a swan, but wholly different from the swan in shape, though by some esteemed a kind of that bird. Its head is large, and is covered with a membrane resembling a hood; its beak is of an oblong figure, and is yellow at its origin, and black at the point, and is somewhat crooked; it is very naked, having only a few feathers scattered over its body, and the rudiments of wings made up of a few naked quills; the hinder parts of its body are very bulky and fat, and it has a tail made of four or five curled greyish feathers, resembling those of the ostrich. Its legs are very thick and strong. See **TAB. of Birds**, N° 6.

Dodo, or *diana*, is a distinct genus of the *gallinae* in the Linnaean system.

DODONÆA, in Botany, the name of a genus of plants, about which authors were very unsettled in their opinions, till Linnaeus characterized it under this name, and ranged it in the *staurandria monogyna* class. Burman has made it a species of the *carpinus*, and Plummer of the *hypericaceae*. The characters are these: the perianthium is divided into three oval, erect, and equal segments; there are no petals; the stamina are eight in number, and are extremely short; the anthers are of an oblong figure, they stand very low, and scarce exceed the length of the cup; the germ of the pistil is of a three-cornered shape; the style is subulated and very long, and the stigma is simple; the fruit is a roundish capsule, having three indented cells, with prominent angles; the seeds are contained each in one cell. The cup has sometimes four segments, and the fruit four cells.

DODO-

DOG

DODONEUS, DODONIAN, in *Antiquity*, an epithet given to Jupiter, as adored, or worshipped, in the temple of *Dodona*, in a forest of the same name.

Dodona, whence the appellation arises, is an ancient city of Epirus, celebrated on divers accounts, as the forest of *Dodona*, the oracle of *Dodona*, and the fountain of *Dodona*.

Dodona's forest was a wood, or grove of oaks, all consecrated to Jupiter. In this was a temple of that god, wherein was the most famous, and, as it is said, the most ancient oracle of all Greece.

Indeed it was not in the temple only that oracles were delivered; the very pigeons that inhabited the wood are said to have done the same.

The origin, and occasion of this fable, we have from Herodotus, who observes, it was founded on this, that *omion*, which in the Thesalian language signifies a pigeon, does likewise signify a witch, or prophetess. But what is more extraordinary is, another tradition among the poets as if the very oaks of the forest of *Dodona* spoke and delivered oracles. This fable is easily deduced from the former; the pigeon in the oak being supposed to speak, it was no great flight of poetical fancy, to introduce the trees themselves speaking, &c. See Vossius de Idololat. lib. 1. cap. 7. p. 27.

The fountain of *Dodona* was in the temple of Jupiter. The ancient naturalists assure us, it had a property of rekindling torches, &c. when newly extinguished. This, no doubt, it did by means of some sulphurous fumes exhaling from it; as we still find a fountain in Dauphine, called the *burning fountain*, &c. It is also said to have extinguished lighted torches; which is no great miracle, since plunging them into a place where the sulphur was too dense, or into the water, must have that effect.

DODRA, in *Roman Antiquity*, a drink prepared from nine different ingredients, which are enumerated by the epigrammatist in the following line.

Jus, aqua, mel, vinum, panis, pipet, herba, oleum, sal.

Vid. Aulon. Epigram. 86.

DODRANS, in *Antiquity*, a division of the AS; being $\frac{1}{2}$ thereof, or nine ancia.

DOE, the female of the buck.

DOG, *Canis*, in *Zoology*, a large genus of quadrupeds. See *CANIS*.

The *dog* in its wild state lives in the woods in many parts of the East; it does not attack a man, neither does it discover any of that familiarity which we find in tame ones. Indeed many other animals may be made as tame as the *dog* by the same treatment; as has been tried on the other, with success.

Authors mention many species of this animal, as the mastiff, wolf-dog, hound, grey-hound, spaniel, water-spaniel, bull-dog, lap-dog, &c. but these are only varieties of the original wild kind, which is of a middle size between the mastiff and greyhound, and distinguished by a tail bending upwards.

Dr. CAIRO, an English physician in the reign of queen Elizabeth, has given the following systematical arrangement of British *dogs*.

I. The most generous kinds	Hounds	Terrier
		Harrier
		Blood-hound
II. Lap-dogs	Spaniel	Gaze-hound
		Grey-hound
		Levrier, or Lyemmer
III. Mergals	Spaniel	Tumbler
		Setter
		Water-spaniel, or Finder
IV. Mergals	Spaniel	gentle, or Comforter
		Shepherd's dog
		Mastiff, or Ban-dog
V. Mergals	Wagge	Turnipit
		Dancer

See *HOUND*, *MASTIFF*, *SPANIEL*, *TERRIER*, &c. Pennant's *Zoology*, vol. 1. p. 59. &c. By a late act, commencing May 1, 1770, stealing of

DOG

dogs incurs a forfeiture of 20*l.* and charges of conviction for the first offence, or an imprisonment for any time between six and twelve months; and for a subsequent offence of not less than 30*l.* and charges, or, on non-payment, imprisonment for twelve months, and public whipping. Persons also in whose custody *dogs*, or their skins, are found, are liable to like penalties.

Dog, sitting. See *SETTING*.

Dog, water. See *SPANIEL*.

The sportsmen generally esteem the black *water-spaniels* above those of any other colour, they being generally the most handy. If there be any farther judgment to be made from the colour, it is, that the spotted or pied are generally the quickest at scent, and the simple liver-coloured the quickest at swimming. These, however, are but very uncertain rules to judge by, and the things principally to be regarded are the *dog's* being of a good breed, and well taught. As to the shape, the head of a good *water-dog* is generally round, and the hair curling, the ears large and broad, and hanging down; the eyes full and lively, the nose short, and the lips like a hound's. The neck should be thick and short, the shoulders broad, the legs straight, and the chest square. The buttocks should be round, and the thighs brawny, the pateras strong and the fore-feet round, the hair in general should be long and curled, not loose and shaggy.

As to the training up of a dog for sporting, the master of him cannot begin when he is too young, the principal thing to be taught being obedience, and that being best taught while the creature is young. As soon as he can lap, he should be taught to couch and lie close at command, and not to dare to stir from that posture till he is ordered, he will soon be brought to this, by beating when he disobies, and encouraging him when he does right. He should always be taught before the times of his eating, and never have his food given him but when he has done something to deserve it. This will teach him always to do well, for the sake of the expected reward. No person should ever interfere in the teaching; for two masters breed a confusion, and the creature never will learn well from them.

The teacher must be careful always to use the same words in his lessons; these words are to be chosen which are the most plain in his sounds, and the most distinct from one another; and when these are once fixed upon, they must never be altered; for the *dog*, being guided wholly by the sound, and not at all by the sense, any alteration of them, though the change be into words of the same sense, quite confounds the creature. The word *down* is short and expressive, and no other need be used when he is ordered to couch; but this being once given him is never to be varied afterwards. The next sound he should be taught after this, is the word of correction; for no lesson can be given but faults will be committed, and no fault should pass without correction or blame; in this case, the word *feral*, spoke angrily, will always be understood. This, at first, should be used with a lash or a blow, and after a time he will know it as a word of displeasure, and it will do for small faults without the blow. Certain words of cherishing and encouragement must also be taught him at the same time, as *good boy*, or the like, using always with those actions and looks of cheerfulness and pleasure, as clapping him on the back, and the like. After these, he must be taught the meaning of some words of advice, to put him in mind of his business, when he is out upon the sport, such as *take heed*, or the like. These will not only set him upon the watch, and make him diligent, but he will also be careful and cunning, and at the same time cheerful and pleased in himself, as knowing that he is doing his master a pleasure.

When the young *dog* is thus far instructed, and knows the meaning of the words of instruction, correction, encouragement, and advice, and will couch and lie down at his master's feet, how and when he pleases, and that with the signal of a word, or look only, he is then to be taught to follow close at his master's heels, by leading him by a line tied to his collar, he is to be carefully taught this, so that when taken out to the sport, he must neither run under the legs, nor hang too far back; this also will tend to the making him the more obedient. When he has been thus taught to follow with a line, he must be taught to follow in the same manner, loose, and without a line, and always be at his master's heels.

The next lesson he is to be taught, is to fetch and carry any thing he is commanded; this must be taught him by way of sport, as a diversion, by flinging a glove at his head, and teaching him to fetch it, and afterwards to catch it when thrown from the hand, and bring it back again; this he is to be encouraged in with cherishing words, and all other means.

The best method of perfecting the creature in this, is by letting

letting him have no food, but what he earns by doing well, always feeding him when he does as he should do. If he carry the glove away, or play wantonly with it, and refuse to bring it back, his master is to use the word of instruction, as *take back*. If this does not bring him to, he is to use the word of correction; and if he does not bring it back at this, he must proceed to blows, and on many other trials he must have nothing given him to eat, till he has done as he ought, and has it by way of reward. When by this means he is taught to well, that he will bring back the glove, whenever it is thrown, and carry it only to his master, though he is in company with other persons, who all call him; he is then to be chastised and encouraged, and taught to bring back any thing else that is thrown, whether sticks, bones, or any thing whatever. After this, he is to be taught to carry dead fowl, and finally live ones, and this with tender a mouth, as not to hurt them; thus he will be taught at length to bring the fowl that his master shoots, without tearing them or hurting a feather.

The next lesson is to be taught by taking him out in the field, and dropping something unknown to him; after he is come to some distance from the place, he is to be sent back to look for it, and if he bring it back, he is to be encouraged. If he bring back a wrong thing, he is to be discouraged for the attempt, and sent back again. By repeating this at different distances, he will be taught to go back ever so far in search of anything; and if he fails in the follow, he is to be chid, beaten, or kept fasting, for it, according to the offence. When he has been practised in all these lessons, he must be taught his business of hunting; he is to be first taught with some fowl, which his master is to stand him in taking, and reward and encourage him when he has done. After this he is to be sent in without assistance to take the fowl alone; and if he succeeds, he is to be encouraged and rewarded, and corrected if he fails. By this practice he will soon become master of his game; but great care is to be taken in teaching him, when he has caught it, to bring it back to the shore, without biting or hurting it.

The next thing to this is the training him to the gun; to this purpose, he must be taught to follow step by step behind his master, and under cover of his shadow, till he has shot, or, when there is occasion, to crouch and lie close, never daring to stir till the gun has gone off; and then, upon the least notice or beckoning, to come and do what he is commanded.

Many of these dogs are so expert, that they will have their ears upon the gun as soon as their master; and the moment the gun is gone off, they will, without bidding, go and fetch it, but this is being too forward; and if he is used afterwards with nets or lime-twigs, he will do great mischief, by running on the birds as soon as they are taken, and tearing the nets, or spoiling the twigs. Obedience is the best quality in this sort of dog; and it is better he should wait for command, than know his business without it.

The sportsmen, who know the time of birds moulting, make a very good use of this sort of dog, taking him with them without gun, net, or any other assistance. The common moulting-time of water-fowl is from June to August; in this time they are not able to fly well, and in some part of it, when their old wing-feathers are off, and the new ones are grown scarce at all, the dog is then to be taken to the sides of rivers and other waters, and set to hunt about the close places, among which they hide themselves at this time; the dog being set to hunt, will easily find them in these retreats, and will take them either by leaping suddenly upon them, or fairly pursuing each of them as have not the use of their wings.

There is also another great use of the dog in driving them without catching them. This is practised only in moorlands and many countries, where they are very numerous. In these countries a proper place is to be sought for, where the birds retire to, and there are planted with nets; then the dog is sent into the waters and places of cover, where they are supposed to be, and this at the moulting-time, when they cannot fly away from him. The alarm he puts them into which he first attacks, soon calls many others together, and there is a large body of them formed, which the dog drives before him like a flock of sheep; and being directed by the sportsman, frightens directly into the places of their retreat, where the nets are placed before him to receive them.

Dog, in *Astronomy*, a name common to two constellations called the *Great* and *Little Dog*; but, among astronomers, more usually, *Canis major*, and *minor*. See *CANIS* major & minor.

Dog-wound, in the *Fossil Law*, a manifest deprivation of an offender against venison in a forest; when he is found

driving after a deer by the scent of a hound, led in his hand. There are four offences in the forest, noted by Manwood: viz. *shale-hound*, *dog-drive*, *hale-hound*, or *hale-hound*, and *hale-hound*. See *STABULUS*, &c.

Dog's flower, in *Botany*, *Sparganium*, from *dog* and *flower*, because the ancients believed this plant would kill dogs. This belongs to the class of *pentandria digyna*, in the Linnaean system. Its characters are: the flower is of one leaf, cut into five acute segments at the top, which turn backward, and in the bottom of the flower are five stamens, which surround the germinas; and there are five filaments, which are scarcely visible. In the centre are two oval germins, which afterwards become two large pointed capsules, having one cell, which is filled with compressed seeds, lying over each other like tiles on a house, and furnished with long festivity down; by which, when the pods are ripe and open, the seeds are waisted by the wind to a considerable distance; so that where these plants grow naturally, they are very troublesome weeds. Linnaeus reckons five, and Miller eleven species.

The down of these plants is in great esteem in France, for stuffing easy chairs, and making very light quilts, which are so very warm and light, that they are very proper covering for many persons. This the French call *serpillier*, and in the southern parts of France, where some of the force will thrive in the open air, and perfect their seeds, there are many plantations of these plants for the sake of the down.

Fancy attributes no virtues to this plant. Dog's Head, in *Botany*, *Ononis*, in *Italy*, a genus of the *pentandria digyna* class. Its characters are: the flower hath one petal, which is spread open, plain, and divided into five parts; the mechanism, which is situated in the centre of the flower, is erect, cylindrical, and of the length of the petal. It hath five filaments, which are parallel to the mechanism, and an oblong bind germin; the envelope becomes a capsule, with two oblong pointed pods, which open longitudinally, and are filled with seeds, lying over each other imbricated, crowned with long down. Linnaeus enumerates nine and Miller seven species, natives of warm climates.

Dog-herry-tree. See *CORONILLA CHERY*.

Dog's-grass. See *DON'S GRASS*.

Dog-day. See *CANICULAR* day.

Dog-fish. See *CANIS* *salmon*.

Dog's, *Cynopsis*, in *Natural History*, the name of a species of dog common in woods and among bushes, and particularly troublesome to dogs. It usually seizes upon the ears, and it is in vain to beat it off; for it returns in a moment, and cannot be prevented but by being killed. It stings very severely, and always raises a blister in the part. It somewhat resembles the flat black fly, so troublesome to cattle. It has no trunk, but has two teeth much resembling those of the wasp. Its wings are always placed so close upon its body, that they are not seen. There are two kinds of it, one larger, and found in woods, and the other common in hedges.

Dog's grass. See *GRASS*.

Dog's Mincy. See *MISERY*.

Dog-rose, a name for the common briar, or hip-tree. It is observable of some kinds of this shrub, that the flowers smell extremely sweet in the night, or very early in the morning, but not at all in the day-time. The reason of which seems to be the same as in all the nocturnal plants, of which there are several kinds, as some of the geraniums, and of the primulas, &c. that is, that the sun exhales and dissipates their odorous effluvia in the day-time as soon as they are exhaled from the flower, but that in these cold times the vapours are condensed, and reach our nostrils in an agreeable manner. Phil. Trans. N^o 114.

Dog's tail grass, *Cynodon*, in *Botany*, a kind of grass called *grasses* by Schrebacher, and other authors; but in the Linnaean system of botany, under this name, it makes a distinct genus of plants, of the *tristandria digyna* class; the characters of which are, that the cup is only a partial covering, lying on one side, but large, and made of two leaves, which are pennated, and remain when the flower is fallen; the glume contains many flowers, and is bivalve, the valves being slender, pointed, and equal in size; the flower is made of two valves, the exterior one is long, hollow, and beakish; the interior flatter, and naked; the filaments are three capillary filaments; the anthers are oblong; the germin of the filament is of a turbinate form; the styles are round, slender, hairy, and crooked; the stigmas are simple; the flower does not open, but nicely encloses the seed, which is simple, of an oblong shape, and pointed at both ends. There are ten species.

Dog's tail, in *Astronomy*. See *TAIL*.

Dog's tongue, in *Botany*. See *HOUSSA* *herba*.

Don's tub, *Fidia*, in *Batany*, *Drau Canis*, or *Erythrina*, a genus of the *beandria mungia* class. Its characters are these: the flower is bell-shaped, composed of six oblong petals, which spread open to their base. It hath six filaments joined to the style, in the centre is situated a three-cornered germ, which afterwards becomes an oblong, obtuse, capsule, with three cells, filled with flat seeds. There are two species. The flowers are propagated by off-sets from their roots, and have a dusky tinge, and a foamy sili, but should not be too often removed.

The powder of the dried root of this plant is said to kill worms in children. Drank in wine, it is an approved remedy for the colic. It is said to be reficitive and restorative, and taken in water, cures children of the epilepsy; it is also esteemed a great provocative to venery.

Don's tank Shell. See **DENTALIS**.

Don-catch. This word, when put into water, is said to flupify fish there, so that they are easily taken with the hand. It is used in America for this purpose, and the method is to tie it to the stem of the fishing boat. It is the wood of a species of *cornus*. See *Canadian Cherry*.

Don-wood of Jamaica. See **ACACIA**.

Don-wood of Virginia. See **BAY-tree**, and **CORALLO-BENDRON**.

DOGA, in *Antiquary*, a large vessel into which the wine was put when newly brought from the vine.

DOGE, the chief magistrate in the republics of Venice and Genoa.

The word properly signifies *dado*, being formed from the Latin *dus*; as *dogate* and *dogado*, from *ducunt*, *duchy*. The *dogate*, or office and dignity of *doge* is elective: at Venice, the *doge* is elected for life; at Genoa, only for two years; he is addressed under the title of *Serenity*, which among the Venetians is superior to that of highness.

The *doge* is the chief of the council, and the mouth of the republic; yet the Venetians do not go into mourning at his death, as not being their sovereign, but only their first minister. In each of the *doges* of Venice is no more than the phantom, or shadow of the majesty of a prince, all the authority being reserved to the republic. He only lends his name to the senate; the power is diffused throughout the whole body, though the answers be all made in the name of the *doge*. If he gives any answers on his own account, they must be very cautiously expressed, and in general terms, otherwise he is sure to meet with a reprimand. So that it is absolutely necessary he be of an easy and pliable disposition.

Antiently, the *doges* were sovereigns; but things are much altered; and at present, all the prerogatives referred to the quality of *doge*, are these which follow: he gives audience to ambassadors; but does not give them any answer from himself, in matters of any importance; only he is allowed to answer according to his own pleasure to the compliments they make to the signory; such answers being of no consequence. The *doge*, as being first magistrate, is head of all the councils; and the credentials which the senate furnishes its ministers in foreign courts, are written in his name; and yet he does not sign them; but a secretary of state signs them, and seals them with the arms of the republic. The ambassadors direct their dispatches to the *doge*; and yet he may not open them, but in presence of the councilors. The money is struck in the *doges'* name, but not with his stamp, or arms. All the magistrates rise, and salute the *doge*, when he comes into council; and the *doge* rises to none but foreign and ambassadors.

The *doge* nominates to all the benches in the church of St. Mark; he is protector of the monastery delle Vergine, and bestows certain petty offices of officers of the household, called *Communiars of the Palace*. His family is not under the jurisdiction of the matter of the ceremonies; and his children may have staff-officers, and possidors in Italy.

His grandeur, at the same time, is tempered with a variety of circumstances which render it burdensome. He may not go out of Venice, without leave of the council, and if he does go out, he is liable to receive affronts, without being entitled to demand satisfaction; and, if any disorder should happen where he was, it belongs not to him, but to the podesta, as being invested with the public authority, to compose it.

The children and brothers of the *doges* are excluded from all the chief offices of state. They may not receive any benefice from the court of Rome; but are allowed to accept of the cardinalate, as being no benefice, nor including any jurisdiction. The *doge* may not divert himself of his dignity, for his sake; and after his death, his conduct is examined by three inquisitors, and five correctors, who sit it with great severity.

DOGGs, machines of iron for burning wood on; also

books fixed in large timbers, for drawing them with bories.

DOGGER, a small ship, built after the Dutch fashion, with a narrow stern, and two masts; viz. a main-mast, and a mizen-mast, principally used in fishing on the *Dogger* bank.

DOGGERS, in the English *Alum-Works*, a name given by the workmen to a sort of stone found in the same mines with the true alum-rock, and containing some alum, though not nearly so much as the right kind. The country of York, which abounds greatly with the true alum-rock, affords also a very considerable quantity of these *doggers*; and in some places they approach so nearly to the nature of the true rock, that they are wrought to advantage. See **ALUM**.

DOGGER-fish, in our *Statute*, seems to be fish brought in the fishing-vessels, called *doggers*, to Blackness Haven, &c. anno 31 Edw. III. stat. 2. cap. 2.

DOGGER-men, fishermen belonging to *dogger*-ships. 25 Hen. VIII. cap. 4.

DOGGET. See **DOUET**.

DOGMA, *dogmas*, a maxim, tenet, settled proposition, or principle, particularly in matters of religion, or philosophy.

DOGMATICAL, something relating to a doctrine, or opinion.

In common use, a *dogmatical* philosopher is one who asserts every thing positively in opposition to a sceptic, who doubts of every thing.

A *dogmatical* physician is he, who, on the principles of the school philosophy, rejects all medicinal virtues not reducible to manifest qualities.

DOGMATICI, DOGMATISTE, a sect of ancient physicians, called also, *logici, logicians*, from their using the rules of logic and reason, in subjects of their profession.

They laid down definitions, and divisions, reducing difficulties to certain genera, those genera to species, and furnishing remedies for them all; supposing principles, drawing consequences, and applying those principles and consequences to the particular diseases under consideration. In which sense the *dogmatists* stand considerably qualified to empirics, and methodists.

The *dogmatists* were those who brought physic into a form, and arrangement, like those of other speculative sciences; defining, dividing, laying down principles, and drawing conclusions; and hence they had also the appellation of *logici* or *d. r. logici*. They also applied themselves to seek the causes of diseases, the nature of remedies, &c.

Eschiratus, a famous *dogmatist*, went so far, that, not content to dissect dogs, and other brute animals, he begged condemned criminals of the magistrates, and opened them while alive, and leached in their veins.

DOITKIN, a kind of base coin of small value, prohibited by the statute 3 Hen. V. cap. 1. Hence came the phrase, *Not worth a doitkin*.

DOLABRUM, among the Romans, a kind of knife used in sacrifices among that people. Vide. Hist. Acad. Inscript. tom. ii. p. 345.

DOLE, in the Saxon and British tongue, signifies a part or portion, most commonly of a meadow.

Hence also *dole-meadow*; a meadow wherein several persons have shares.

The word still signifies a share; a distributing, or dealing of alms; or a liberal gift made by a great man to the people.

DOLLE, in the *Law of Scotland*, is used for a malevolent intention. The word is taken from the civil law term *dolus*.

Dole, in the law of Scotland, as well as in the civil law, is an essential ingredient to constitute an action criminal. In crimes wherein the will, not the event, must be regarded, no negligence can equal *dole*, unless the negligence be so extremely lapse, as not to be conceivable without implying *dole*.

Under *dole* are comprehended the vices and errors of the will, which are immediately productive of the criminal fact, though not premeditated, but the effect of sudden passion. In this respect *dole* differs from what the English law calls malice. However both laws agree in this, that the bare intention never brought forth into act, is no crime; yet giving counsel to perpetrate is criminal, if the fact is done pursuant thereto.

DOL-fish, in our *Statute*, seems to be that fish, which the fishermen, yearly employed in the North seas, do of custom receive for their allowance or shares. Vide. stat. 31 Hen. VIII. cap. 7.

DOLET, in *Natural History*, a word used by some writers, in *Medicine*, for red vitriol, or colicohar of vitriol.

DOLG-BOTE, in the Saxon *Law*, a recompence, amend, or satisfaction, made for a scar or wound.

DOLICHODROMUS, in the *Ancient Exercises*, one who ran the length of a *Dolichos*.

DOLICHOLITHOS, in *Natural History*, a name given by some authors to a species of stone, of a blackish colour, and of the shape of a kidney-bean, found in great abundance about Tyrol, and yielding a smell on rubbing.

DOLICHOS, in *Aetiology*, a word used by different writers in different senses. The ancient physicians understood by it long or prolix, and used it in this sense in their description of diseases. Others used it for the fruit or pod of the kidney-bean. *Stida* makes it signify a race, or course, of twelve stadia, or of twenty-four.

DOLICHOS, in *Botany*, the name of a genus of plants, of the *diadelphis decurrens* class, the characters of which are these: the perianthium is composed of one leaf; it is very short, and is divided into four segments at the end; the upper segment is emarginate; the flower is of the papilionaceous kind; the vexillum is roundish, large, and emarginate, and is wholly bent backward; and there are two callous oblong bodies running parallel to one another, and growing in the tender part of the vexillum towards its base; these compress the ale together; the ale are of an obtuse oval figure, and are of the length of the carina; the carina is compressed, the filaments are diadelphous, and the anthers are simple; the germen of the pistil is slender and compressed, the style points upward, the stigma is bearded, and runs from the middle of the inner part of the style to its apex, which is callous and obtuse. The fruit is a large pod, of a pointed oblong figure; it is bivalve, and is divided into two cells; the seeds are of an elliptic figure, and usually are compressed; this plant approaches greatly to the phacelia, but is distinguished at first sight by the carina of the flower, which is not spiral, as in that genus.

DOLMAN, a kind of long callock worn by the Turks, hanging down to the feet, with narrow sleeves, buttoned at the wrist.

The Turks, both men and women, wear drawers next the skin; over that a shift, or shirt; and over the shirt a *dolman*. In summer it is linen, or muslin; in winter, satin, or stuff.

DOLUM, in *Natural History*, the name of a genus of shells, called by some *scapha globosa*, and by the French, *tenues*. The characters are these: it is an univalve shell, with a globose, or round bell, with a lax aperture, sometimes smooth, and sometimes dentated. The clavicle is either moderately umbonated or depressed; and the columella is in some species smooth, in others wrinkled. Some authors have called these *scapha ampullacea*; and they have had, at times, many other names, but all tending to the same sense, and expressing the globular figure of the body, which is the great character by which these are distinguished from all other shells. See *Tak. of Shells*, N° 15.

The Persian shell, so much esteemed in cabinets, is a very singular one; but the globose figure of its body evidently refers it to this genus, though it differs in many other particulars from all the species of it. Aldrovandus could not tell what to make of the shells of this genus, but has thrown them together at the end of his book, observing, that they seemed to be of the turbanated kind, but that they want the turban.

Of the round unibonated *dolum*, there are six species; of the oblong and smooth, five species; of the oblong costated, and umbonated, seven species; of those with long and arched tails, five species; of that series, which from their shape are called *bulus*, seven species; to which is added a very rare species of *dolum*, which is falsicated, of a blue colour on the outside, and white within; this is called by some the *vitula caribea*; and there is an olive-coloured shell of the same kind.

DOLLAR, or **DALLER**, a silver coin, nearly of the value of the Spanish piece of eight, or French crown. *Dollars* are coined in divers parts of Germany and Holland; and have their diminutives, as *semi-dollars*, *quarters-dollars*, &c.

They are not all of the same fineness, nor weight. The Dutch *dollars* are the most frequent. In the Levant they are called *asmani*, from the impression of a lion thereon.

DOLOR, *Pain*, in *Medicine*, Galen, in his first book of Elements has defined pain, in opposition to pleasure, to be a disagreeable and troublesome sensation. Of pain there are various kinds; one is attended with pulsation; another with a sense of incumbent weights; another with a tension. There is a pain which attends erosion, incision, puncture, and perforation, comprehended with these, and the like differences, under the name of acute; and lastly there is a pain attended with a torpor or numbness.

Pains considered as *prognostics* of a crisis. Pains affect the patient in the beginning of a disease, or afterward: in

the beginning they are for the most part to be accounted as pathognomonic signs, signifying that some part among the viscera labours under an inflammation. Thus it is when the pain begins with a fever, and a tumor or tension of some parts, and these sorts of pain are called inflammatory. It is best for the patient when these *pains* are neither violent nor continual; but after a short duration, are either quite removed, or else mitigated, and are, beside, attended with no other pernicious signs. But it is best of all, and safest in such a case, when these pains cease or remit with reason, or for some manifest cause; as it happens when such cessation or remission is owing to some beneficial evacuation, excited by nature or procured by art; such as venesection, spontaneous bleeding at the nose, sweat, stool, spitting, or when a subsequent fever removes the pain by virtue of its heat, as we learn from Hippocrates.

As for those *pains* which arise on the progress of the distemper, those which the physicians call critical, are thought to be the more kindly and favourable; because partly as a sign, and partly as a cause, they prognosticate a happy crisis. As a sign they indicate an hemorrhage, vomiting, or some other evacuation, agreeable to the observation of Hippocrates. 1. Epid. sect. 2.

These are the *pains*, which, by indicating a happy crisis, prognosticate a recovery; such, in particular, are the *pains* which affect, sometimes for a long time together, the ignoble parts which lie remote from the viscera, and are principally to be regarded, as well as other signs, when they happen on a critical day, with manifest tokens of concoction; in which circumstance we may with confidence predict a recovery, if none of the mortal signs appear.

Pains prognosticating death. All pains affecting a noble part of the body are bad; whether they are produced together with the disease, and so are esteemed pathognomonic signs, or are excited afterward; for the former, in conjunction with other pathognomonic, or proper signs, form a prognosis. Thus a violent and continual pain of the head in a phrensy, with other destructive signs of a phrensy, is mortal. Some *pains* are generally mortal, from the excellence and usefulness of the part which they affect: those, for instance, which seize the heart, or cause strangulations in the mouth of the stomach, the fauces, head, ears, breast, or bladder. For *pains* in these members are always pernicious, and especially when attendant on a continual fever, with other bad symptoms, indicating an inflammation, which are generally mortal.

Pains in the viscera and noble parts, which affect not the patient in the beginning of acute distempers, but are felt afterward in the progress of the disease; if severe and constant, are to be esteemed very pernicious; as shewing some noble part of the viscera to be afflicted with a high inflammation, accessory to the fever, and not to be subdued but by extraordinary strength of nature. Wherefore these *pains* are usually succeeded by very formidable symptoms, such as a comets in the extreme parts, which is the ordinary consequence of violent *pains*, according to Hippocrates. 7. Aph. 36.

Thus may be seen what judgment is to be made, and what prognostics to be drawn, from pains indicating the viscera, or noble parts; but if these *pains* are accompanied or succeeded by some mortal sign, no less than the destruction of the patient is indicated. The same consequence may be prognosticated from a variety of pains affecting the noble parts, or other severe symptoms of a different kind, appearing at the same time; for these, as they are indications of several dangerous disorders in conjunction, so when attendant on *pains*, or a multiplicity of *pains*, they portend nothing but the worst of events. For if nature finds it difficult to subdue one considerable distemper, it must certainly find and give way to the joint attacks to many diseases, unless upheld by an extraordinary measure of strength.

Pains in the ignoble parts we have before declared to be good; and if attended with a concoction of the humours, or considerable duration, are effectual in removing, or at least in mitigating the fever, with its attendant symptoms, and putting the patient in a better state. Such *pains* begin on critical days, and are not concerned in exacerbating any of the symptoms. But *pains* in the ignoble parts, in the beginning of a disease, when all things are crude, by which no symptoms of the noble parts are removed or diminished, but rather exacerbated and multiplied, and the sick rendered worse, are of a bad kind. But *pains* arising in the ignoble or remote parts, are most to be dreaded, when preceded by a fever, and other no less feverish and dangerous symptoms, under which the patient grows worse.

Pains of the ignoble parts are so less formidable, and to be suspected, when they vanish, and become insensible

on a sudden; or when they begin in a remote part, and thence remove toward the viscera; which indicate a conflux of humours to the noble parts.

Alecepiades considered pain as a principal indication for bleeding; for he thought pain was caused by a retention of the larger molecules, in the pores or passages, which nothing but bleeding could dissolve. The rule is excellent, whatever the reason he gives for it may be; for it would be difficult to lay down a maxim in physic either more universal, or of greater importance. James.

Pain, considered as a symptom of a disease, makes a considerable article in a palliative cure.

Pain is mitigated, or allayed, divers ways; as, 1. By diluting and softening acrimonies, with warm water mixed with flour, applied by way of drink, fomentation, clister, or bath. 2. By resolving and washing away obstructions, by the same means, and rebovents. 3. By relaxing the nervous vessels, with drinks, fomentations, baths, relaxants, anodynes, and aperients. 4. By correcting the acrimony itself with proper remedies. 5. By freeing the obstructions, obdurate, and acrimonious parts from the too great profuse of the vital humour; and by fastening, and separating, and depurating, them. 6. By relaxing or descending the sense by narcotics, either internally or externally.

DOLPHIN, *Delphinus*, in the Linnæan system of Zoology, makes a distinct genus of fishes of the order of cetæ, and class of mammalia; the characters of which are, that there are teeth in both jaws, and a pipe in the head.

In the Arridan system of Ichthyology, *delphinus* is also the name of a genus of the plagiuri, or cetaceous fishes; the characters of which are these: the teeth are placed in both the jaws, the pipe or opening is in the middle of the head, and the back is always pinnated.

The species of this genus are these: 1. The *Delphin*, with a coniform body, with a broad back, and a sub-obtusif snout: this is the *Stenurus*, or porpoise. 2. The *delphin*, with an oblong fusiform body, with a long acute snout: this is the *delphinus* of the generality of authors, and is called the *porpoise* also by the English. 3. The *delphin* with the back ridged upwards, and with broad serrated teeth: this is the *orca* of authors, called by us the *grampus*, and *north cape*; the body of this fish is so thick, that its breadth is equal to half its length. See PORPOISE.

The name *delphinus* is of Greek origin, and is supposed by some to be derived from the word *delphos*, a pit or bog; and, according to others, from the word *delphos*, volva, this fish being of the viviparous kind, and one of those few which have the volva and penis in the different sexes, like those of land animals.

All the nations who have given this fish their several names, have derived them from its resemblance to the same creature, a hog; and this not without reason, as there is much analogy between the two animals, the *delphin* being as fat as the hog, and having his initials extremely like those of that quadruped; but in this there has yet been some confusion, as the common porpoise, which much resembles the *delphin* in many respects, has also been indistinctly called by the same name with that fish. The difference between the two is, that the *delphin* has a much longer snout or nose, sticking out somewhat in form of a goose's bill, and is in the whole a longer, slenderer, more fleshy, and less fat fish, and is the larger of the two. The *porpoise* or *porpise* is fatter, smaller, broader backed, and has a more obtuse and shorter snout.

The *delphin* is a cetaceous fish, covered with a smooth, but very tough and firm skin; its body is long and rounded, and its back prominent. Above the snout it has a pipe, by which it throws out the water necessarily taken in with the food. These fish are supposed to live a great number of years. The figures of them on some antique medals and coins, which represent them crooked and unnatural, have been conceived originally by persons who had seen them playing about on the surface of the water, in which case they sometimes deceive the eye, and appear crooked; from these probably our sign-painters took their idea of the *delphin*. They are an extremely swift fish in swimming, and are able to live a long time out of the water, though they can continue but a little while under it without air; hence they are sometimes taken up dead by fishermen in their nets, having been suffocated by being forcibly kept under water. They have been known to live three days on dry ground. Willoughby, Hist. Eng. p. 30.

This fish was consecrated by the ancients to the gods, and called the sacred fish. Scarcely an accident could happen at sea, but the *delphin* offered himself to convey to shore the unfortunate. The story of Arion, the musician, is related by Ovid, Fasti, lib. ii. ver. 113. It was formerly reckoned a great delicacy in this country.

DOLPHIN is also a name given by the English to the fish called *hippuris*, by the generality of authors; but by some *hippale* and *equale*, and by others *dorad*. According to the new system of Arædi, this fish is a species of the *corphæus*, and is distinguished from all the other kinds, by its having a forked tail. See HIPURIS and CORPHÆUS.

DOLPHIN, *Delphinus*, in Astronomy. See DELPHINUS.

DOLPHIN of a canon, in Gunners, are the two handles placed on the second reinforce ring of brass guns, resembling the fish of that name. They serve for mounting and dismounting the guns.

DOLPHIN of the mast, in Sea-Language, is a peculiar kind of wreath, formed of platted cordage, to be fastened occasionally round the masts, as a support to the PUMPERING, whose use is to sustain the weight of the fore and main-yards, in case the rigging or chains, by which those yards are suspended, should be shot away in the time of battle.

DOM, or **DOW**, a title of honour, originally Spanish, though used occasionally in other countries. See TITLE.

It is equivalent to *mylord*, *for* or *lord*, *mylord*, *lord*, *mylord*, &c.

Gollart, in his Mem. des Bourgs. liv. v. chap. 11, assures us, that the first on whom the Spaniards conferred the title, was Don Pelayo; when, upon their being routed, and driven out, by the Saracens, at the beginning of the eighth century, they rallied again on the Pyreneans, and made him king.

In Portugal, nobody is allowed to assume the title of *don*, which is a badge or token of nobility, without the king's leave.

DOM is likewise used in France among some orders of religious, as the Chartreux, Benedictines, &c.

We say, the reverend father *don Calmet*, *don Alexis*, *don Balthazar*, &c.

In the plural they write *doms*, with an *i*, in speaking of several. RR. PP. *doms* Claude du Rubic, and Jacques Douceur.

The word is formed from the Latin *dominus*, or *dominus*, of which it is an abbreviation. *Domus* is found in diverse Latin authors of the barbarous age, Onuphrius assures us, it was a title first given to the pope alone; then to the bishops, abbots, and others, who held any ecclesiastical dignity, or were eminent for virtue and religion. At length it was usurped by the mere monks.

Some say, the religious declined the title *dominus* out of humility, as belonging to God alone; and assumed that of *dominus*, as expressing inferiority, *quasi minor dominus*. Indeed, the appellation *dominus* for *dominus* appears very ancient, if we consider the surname of Julia, wife of the emperor Septimius Severus, who is called on medals, *AVLIA DOMNA*, for *JULIA DOMINA*.

DOM and **DOM**, words used in ancient charters, signifying a power of judging, and security in possessing. Hence *doms* men, who were persons appointed to determine suits and controversies between parties. See DAY'S MAN.

DOM-BOOK. See DOMESDAY.

DOMAIN, the inheritance, estate, or possession, of any one. See DEMESNE.

Message derives the word from *dominion*, written in the barbarous Latin for *DOMINUM*.

DOME, or **DOOM**, signifies judgment, sentence, or decree. The homagers oath, in the Black Book of Hereford, ends thus: So help me God at his holy *dom*, and by my trowthe.

DOMS, in Architecture, a spherical roof; or a work of a spherical form raised over the middle of a building, as a church, hall, pavilion, vestibule, stair-case, &c. by way of crowning, or acroter. See TAB. Architecture, fig. 40. D.

The word is formed from the barbarous Latin, *doma*, which signified a roof, or open porch; as is observed by Papias. It is frequent in the corrupt Latin authors, who borrowed it from the Greeks, among whom *trallus*, or *trallum*, is a common name for any round building; such as the palace of Constantinople, wherein was held the council thence called in *trallu*.

Doms are the same with what the Italians call *capitoli*; and we frequently *capoli*: the Latins, according to Vitruvius, *tholi*.

They are usually made round; though we have instances of square ones; as those of the Louvre; and others that are polygons, as that of the Jesuits church in the Rue St. Antoine at Paris. They have usually columns ranged around their outside, both by way of ornament, and to support the vault.

DOMT, a flat, is that whose sweep, or contour, is less than a hemisphere.

DOMT, *cy of a*. See EVE.

DOMT, in Chemistry, the arched cover of a reverberatory furnace. See REVERBERATORY.

DOMENGER, in *Middle Age Writers*, is sometimes used for DAMSEL.

DOMES-DAY, or DOOMS-DAY-Book, *Liber iudicarius vel consularis Anglie*, the judicial book, or book of the survey of England; a most ancient record made in the time of William the Conqueror, upon a survey, or inquisition, of the several counties, hundreds, tithings, &c.

Its name is formed from the Saxon *dom*, doom, judgment, sentence and day, which has the same force; so that *doms-day* is no more than a reduplicative, importing judgment day.

But some condemn this etymology as whimsical; and contend that if it was just, the Latin for *domsday* would be *diei iudicii*; whereas, as appears above, it is styled *Liber iudicarius, vel consularis Anglie*. Butler, in his *Celtic Dictionary*, hath the word *dom*, which he translates *sear, seigneur* (and hence the Spanish word *due*), as also the words *days*, and *doms*, which he renders *prestationis, advertisement*. *Domsday* therefore signifies the lord's or king's proclamation, or advertisement, to the tenants who hold under him; and agrees well with great part of the contents of this famous survey. Observations on the Statutes, p. 193, note (m).

The drift, or design of the book, is to serve as a register, by which sentence may be given in the tenures of estates; and from which that need question, whether lands be ancient demesne, or not, is still decided. Its contents are summed up in the following verses:

*Quid desiderat filius, quæ, quanta tribuit,
Nominis quid unius, quæ vestigia, quantum
Desuper teneat, fœdali solvere iure,
Quæ sunt exempti, vel quasi angaria damnata,
Quæ sunt vel gubæ servæ, vel conditionis,
Quæque mancipia patris iure ligatur.*

This book is still remaining, fair and legible; consisting of two volumes, a greater and a less; the greater comprehending all the counties of England, except Northumberland, Cumberland, Westmorland, Durham, and part of Lancashire, which were never surveyed; and except Essex, Suffolk, and Norfolk, which are comprehended in the lesser volume, which concludes with these words: *Annus millesimus ultimus factus ab incarnatione Domini, vigesima vero regis Willelmi, facta est ista descriptio non solum pro his tunc constitutis, sed etiam viis.* It is called *Liber iudicialis*, because a just and accurate description of the whole kingdom is contained therein; with the value of the several inheritances, &c.

It was begun by five justices, assigned for that purpose in each county, in the year 1086, and finished in 1086. Camden calls it *Guillelmi Librum consularium*, king William's Tax-book.

This book was formerly kept under three different locks and keys; one in the custody of the treasurer, and the others of the two chamberlains of the exchequer. It is now deposited in the chapter-house at Westminster, where it may be consulted, on paying to the proper officer a fee of 6s. 8d. for a search, and 4d. per line for a transcript.

Our ancestors had many *doms-books*. We are told by Ingulphus, that king Alfred made a like register with that of William the Conqueror. It was begun upon that prince's dividing his kingdom into counties, hundreds, tithings, &c. when an inquisition being taken of the several districts, it was digested into a register, called *Doms-book*, q. d. the *Judgment-book*, and was deposited in the church of Winchester; whence it is also called the *Winchester-book*, and *Ratusus Ponten*. This book is said to have been extant so late as the reign of king Edward IV. but is now unfortunately lost. It probably contained the principal maxims of common law, the penalties for misdemeanors, and the forms of judicial proceedings. And upon the model of this *Doms-book* it is, that the *Domsday* of the Conqueror was formed.

That of king Alfred referred to the time of king Ethelred; and that of the Conqueror, to the time of Edward the Confessor; the entries being thus made, *G. tenet res Guillelmi in dominis, &c. veluti filius domini*, &c. T. R. E. valuerat q. d. it is worth to much temper regis Edwardi, in the time of king Edward.

There is a third *Doms-book*, or *Doms-day-book*, in quarto, differing from the other in folio, rather in form than matter. It was made by order of the time Conqueror; and seems to be the more ancient of the two.

A fourth book there is in the exchequer, called *doms-day*; which, though a very large volume, is only an abridgement of the other two. It has abundance of pictures, and gilt letters at the beginning, which refer to the time of Edward the Confessor. There is also a fifth book called *Doms-day*, and the same with the fourth now mentioned.

DOMESTIC, from *domus*, house, a term of somewhat more

extent than that of *servant*; the latter only signifying such as serve for wages, as footmen, lacquies, porters, &c. whereas *domestic* comprehends all who act under a man, compose his family, and live with him, or are supposed to live with him. Such are lecturers, chaplains, &c.

Sometimes *domestic* goes farther, being applied to the wife and children.

DOMESTIC KING, *rex domesticus*. See *Toga*.

DOMESTICUS, *domesticus*, in *Antiquis*, was a particular officer in the court of the emperors of Constantinople.

Fabrot, in his *glossary* on Theophrastus Simocatta, defines *domesticus* to be any person entrusted with the management of affairs of importance; a counsellor, *regis*, *senatus*, *procuratoris*, *aliquis*, *et ceteris*, *et ceteris*, *et ceteris*.

Others hold, that the Greeks called *domesticus* those who at Rome were called *comites*, particularly, that they began to use the name *domesticus*, when that of count was become a name of dignity, and ceased to be the name of an officer in the prince's family.

Domestici, therefore, were such as were in the service of the prince, and assisted him in the administration of affairs; both those of his family, those of justice, and those of the church.

The grand *Domesticus*, *Magister officiorum*, called also absolutely the *domesticus*, seated at the emperor's table, in quality of what we occidentals call *chancellor*. Others say, he was rather what we call a *minister*.

DOMESTICUS *maior* did the office of grand marshal, or steward.

DOMESTICUS *rei domesticæ* acted as master of the household. DOMESTICUS *scholarum*, or *legionum*, had the command of the reserved forces called *scholæ palatine*, whose office was to execute the immediate orders of the emperor.

DOMESTICUS *marium*, had the superintendence of all the fortifications.

DOMESTICUS *regium*, that is, of the east and west, had the care of public causes, much like our attorney or solicitor-general.

DOMESTICUS *exercitus*, or of the military cohorts.

There were also other officers of the army, who bore the appellation *domestici*, which signified no more than commander, or colonel. Thus, the *domestici* of the legion called *optimæ*, was the commander thereof.

DOMESTICUS *thesauri*, or *thesauri*, whereof there were two in the church of Constantinople; one on the right side of the church, and the other on the left. They were also called *protospatharii*.

Dom. Magri distinguishes three kinds of *domestici* in the church: *domestici* of the *palatium*, *domestici* of the imperial clergy, that is, master of the emperor's chapel; and *domestici* *dispositivi*, or of the empire. There was another order of *domestici*, inferior to any of those above mentioned, called *patriarchal domestici*.

DOMESTICI was also the name of a body of forces in the Roman empire. Panciroli takes them to have been the same with those called *protospatharii*, who had the chief guard of the emperor's person, in a degree above the praetorians; and who under the Christian emperors had the privilege to bear the grand standard of the cross.

They are supposed to have been 3500 before Julian's time, who added 2000 more to the number. They were divided into several companies, or bands, which the Latins called *cohortes*, some whereof are said to have been instituted by Gordian. Some of them were cavalry, and some infantry.

Their commander was called *comes domesticorum*.

DOMICELLARY *convent*. See *Canons*.

DOMICELLUS. See *Dame*.

DOMIFYING, DOMIFICATION, in *Astronomy*, the dividing or distributing the heavens into twelve houses; in order to erect a theme, or horoscope, by means of six great circles, called *circuli* of position.

There are diverse ways of *domifying*, according to diverse authors. That of Regiomontanus, which is the most usual, makes the circle of position pass through the intersections of the meridian, and horizon. Others make them pass through the poles of the world, or the equator; and others through the poles of the Zodiac.

DOMINANT of a *mode*, in *Music*, that found which makes a perfect fifth to the final, in authentic modes; and a third to the final or sixth, to the lowest chord of a plagal mode.

DOMINARUM *Aqua*, a name given by Myrrhine to a distilled water, which he recommends to the ladies to facilitate delivery.

DOMINATION, in *Theology*, the fourth order of angels, or blessed spirits, in the hierarchy; reckoning from the seraphim. See *Hierarchy*, and *Seraph*.

St. DOMINGO *Company*. See *Company*.

DOMINI *Annus Domini*. See *Annus*.

Bull in Cane Domini. See *Bull*.

DOMINIAL

DOMINICAL offices. See **OFFICE.**

DOMINICAL Letter, in Chronology, properly called *Sunday Letter*, one of the seven letters of the alphabet ABCD EFG, used in almanacs, ephemerides, &c. to denote the Sundays throughout the year.

The word is formed from *Dominica*, or *Dominicus dies*, Lord's day, Sunday.

The *Dominical letters* were introduced into the calendar by the primitive Christians, in lieu of the nundinal letters in the Roman calendar.

These letters, we have observed, are seven: and that, in a common year, the same letter should mark all the Sundays will easily appear; inasmuch as all the Sundays are seven days apart, and the same letter only returns in every seventh place.

But in bissextile, or leap-year, the case is otherwise: for by means of the intercalary day, either the letters must be thrust out of their places for the whole year afterwards, so, e. g. as that the letter which answers to the first of March, shall likewise answer to the second, &c. or else the intercalary day must be denoted by the same letter as the preceding one. This latter expedient has been judged the better, and accordingly the Sundays after the intercalary day have another *Dominical letter*.

Hence, 1. As the common Julian and Gregorian year consists of 365 days, i. e. of 52 weeks, and one day; the beginning of the year, every common year, goes forward by one day: thus, e. g. if this year the beginning, or first day fall on a Sunday, the next year it will fall on Monday, the next on Tuesday, &c. Consequently, if A be the *dominical letter* of the present year, G will be that of the next year, because, as it is supposed to begin on Monday the Sunday will fall on the seventh day; and so on in a retrograde order.

2. As the Julian, and Gregorian bissextile, or leap-year, consists of 366 days, i. e. 52 weeks and 2 days, the beginning of the next year after bissextile goes forward 2 days. Whence, if in the beginning of the bissextile year, the *Dominical letter* were A, that of the following year will be F: for if the bissextile or leap year begins on Sunday, it will end on Monday; and the next year will begin on Tuesday, so that the first Sunday must fall on the first of January, to which is annexed the letter F.

3. Since in leap-years the intercalary day falls on the 24th of February, in which case the 24th and 25th days are considered as one day, and denoted by the same letter; after the 24th day of February the *Dominical letter* goes back one place: thus, if in the beginning of the year the *Dominical letter* be A, it will afterwards be G. This day is now added to the end of February, and thence the change takes place.

4. As every fourth year is bissextile, or leap-year, and as the number of letters is 7; the same order of *Dominical letters* only returns in 28 years; which, without the interruption of bissextiles, would return in 7 years; 5. Hence the invention of the solar cycle of 28 years; upon the expiration whereof the *Dominical letters* are restored successively to the same days of the month, or the same order of the letters returns.

To find the *DOMINICAL letter* of any given year. Seek the cycle of the sun for that year, as directed under CYCLE; and the *Dominical letter* is found corresponding thereto. When there are two, the proposed year is bissextile; and the first obtains to the end of February; and the last for the rest of the year.

The *Dominical letter* for any year of the present century may be found by the following canon:

Divide the odd years, their fourth and four by seven,
What is left subtract from seven, the letter is given.

Thus for the year 1778, the letter will be D.

The *Dominical letter* may be found universally, for any year of any century, thus:

Divide the centuries by four; and twice what does remain
Take from six 4, and then add to the number you gain
Their odd years and their fourths, which, dividing by seven,
What is left take from seven, and the letter is given.

Thus the letter for the year 1878 is F.

The reason of the foregoing rules may be easily explained. Every common year brings the *Dominical letter* one backward, and every leap-year two; therefore to any number of years, under 100, add its fourth part for the leap years, omitting fractions; and the sum will be the number of times the letter has shifted backward during that number of years, which, being divided by 7, leaves a remainder, that will be the number of the letter of the present year, reckoning from the letter belonging to the last centennial year, in a retrograde order; or the complement of the remainder to 7, will be the present *Dominical letter* in a direct order. It is also evident, that four Gregorian centuries, containing three centennial com-

Vol. II. No 101.

mon years, which remove the letter two forward, and one centennial leap-year, which removes it one forward, will complete a revolution of the letter. Thus the *Dominical letter* of 1600 is A; of 1700 C; of 1800 E; of 1900 G; of 2000 A, &c. Therefore A, the fifth letter backward from G, is the *Dominical letter* of a bissextile centennial year; and 6 must be added to the odd years and their fourths, and the sum be divided by 7, in order to obtain the letter of any year in the next century, or the seventeenth; and, as the first common centennial year brings the letter two forward from A, or two less than six backward from G, the remainder, after dividing the centuries by 4, must be doubled, and so we shall have 6-2=4 to be added to the odd years, and their 4th, in the second common century; and 6-4, or 2, must be added in the third; and 0 in the 4th, because the Gregorian bissextile recurs, and the number of centuries may be divided by 4, without leaving any remainder.

By the reformation of the calendar under pope Gregory, the order of the *Dominical letters* was again disturbed in the Gregorian year; for the year 1582, which at the beginning had G for its *Dominical letter*, by the retrenchment of ten days after the 4th of October, came to have C for its *Dominical letter*; by which means the *Dominical letter* of the ancient Julian calendar is four places before that of the Gregorian; the letter A in the former answering to D in the latter.

DOMINICAL, in Church History. The council of Auxerre, held in 578, decrees, that women communicate with their *dominical*. Some authors contend, that this *dominical* was a linen cloth, wherein they received the species; as not being allowed to receive them in the bare hand. Others will have it a kind of veil, wherein they covered the head. The most probable account is, that it was a sort of linen cloth, or handkerchief, wherein they received, and preserved, the eucharist, in times of persecution, to be taken on occasion at home. This appears to have been the case by the practice of the first Christians, and by Tertullian's book *Ad Uxorem*.

DOMINICAL was also formerly used in the same sense with *ROMILY*.

DOMINICANS, an order of religious, called in some places *Jacobins*, and in others *Preaching Friars*, or *Preaching Friars*. See **JACOBINS**, &c.

The *Dominicans* take their name from their founder Dominic de Guzman, a Spanish gentleman, born in 1170, at Calaroga, in Old Castile. He was first canon and archdeacon of Osma; and afterwards preached with great zeal and vehemence against the Albigenses in Languedoc, where he laid the first foundation of his order. It was approved of in 1215, by Innocent III. and confirmed in 1216, by a bull of Honorius III. under the title of St. Augustine; to which Dominic added several austere precepts and observances, obliging the brethren to take a vow of absolute poverty, and to abandon entirely all their revenues and possessions; and also the title of *Preaching Friars*, because public intrusion was the main end of their institution.

The first convent was founded at Tholouse by the bishop thereof, and Simon de Montfort. Two years afterwards they had another at Paris, near the bishop's house; and some time after, a third in the rue St. Jacques, St. James's street, whence the denomination of Jacobins.

Just before his death, Dominic sent Gilbert de Fresney, with twelve of the brethren, into England, where they founded their first monastery at Oxford in the year 1221, and soon after another at London. In the year 1276, the mayor and aldermen of the city of London gave them two whole streets by the river Thames, where they erected a very commodious convent, whence that place is still called Black Friars, from the name by which the *Dominicans* were called in England.

St. Dominic, at first, only took the habit of the regular canons, that is a black cowl, and rochet; but this he quitted in 1216, for that which they now wear, which, it is pretended, was shewn by the blessed Virgin herself to the beatified Renard d'Orleans.

This order is diffused throughout the whole known world. It has forty-five provinces under the general, who resides at Rome; and twelve particular congregations, or reforms, governed by vicars-general.

They reckon three popes of this order, above sixty cardinals, several patriarchs, a hundred and fifty archbishops, and about eight hundred bishops; besides masters of the sacred palace, whose office has been constantly discharged by a religious of this order, ever since St. Dominic, who held it under Honorius III. in 1218.

The *Dominicans* are also inquisitors in many places. See **INQUISITION**.

Of all the mendicant orders, none enjoyed a higher degree of power and authority than the *Dominicans* friars.

whose credit was great and their influence universal. But the measures they used in order to maintain and extend their authority, were so pernicious and cruel, that their influence began to decline towards the beginning of the sixteenth century. The tragic story of Jerzer, conducted at Bern in 1509, for determining an uninteresting dispute between them and the Franciscans, relating to the immortality of the soul, will reflect indelible infamy on this order. See an account of it in Burnet's Travels through France, Italy, Germany, and Switzerland, p. 31, or Motheim's Eccl. Hist. vol. iii. p. 294, 8vo. They were indeed perpetually employed in stigmatizing with the opprobrious name of heresy numbers of learned and pious men; in encroaching upon the rights and properties of others, to augment their possessions; and in laying the most iniquitous snares and stratagems for the destruction of their adversaries. They were the principal counsellors, by whose instigation and advice Leo X. was determined to the public condemnation of Luther. The papal see never had more active and useful abettors than this order, and that of the Jesuits.

The dogmas of the Dominicans are usually opposite to those of the Franciscans.

There are also nuns, or sisters of this order, called in some places, *Preaching Sisters*. These are even more ancient than the friars; St. Dominic having founded a society of religious maidens, at Promieles, some years before the institution of his order of men; viz. in 1205.

There is also a third order of Dominicans, both for men and women.

DOMINIUM, **DOMINION**, in the *Civil Law*, denotes the absolute power, or property, of a thing, to use or dispose of it how we please.

Dirigendum dominium is the right alone of dominium; and *dominium utile*, the profit rebounding from it. The wife retains the *dominium dirigitum* of her jointure, and the *dominium utile* passes to her husband. With respect to land, he who pays rent, has the *dominium utile* of the lands; and the lord he pays it to, the *dominium dirigitum*.

DOMINIUM, **DOMINION**, or **DOMAINE**, in our *Ancient Customs*, denotes a rent due to the lord, where the property is not his.

DOMINORUM, *Affiliis*. See **AFIDATIO**.

DOMINUS, in *Ancient Times*, a title prefixed to a name, usually to denote the person either a knight, or a clergyman. See **VICE-DOMINUS**.

Though the title was sometimes also given to a gentleman not dubbed; especially if he were lord of a manor. See **DON**, **GENTLEMAN**, and **SIR**.

In Holland, the title *dominus* is still retained, to distinguish a minister of the reformed church.

Redi pando DOMINUS *transit*. See **REVO**.

DOMO reparanda, a writ that lies for one against his neighbour, by the fall of whose house he fears damage to his own. Reg. of Writs, fol. 153. In which case the civil law has the action *de domo repara*.

DONARIA, among the *Ancients*, in its primary signification, was taken for the places where the oblations offered to the gods were kept; but afterwards was used to denote the offerings themselves; and sometimes, though improperly, the temples.

DONATION, **DONATIO**, an act, or contract, whereby a man transfers to another, either the property, or the use, of the whole, or a part of his effects, as a free gift.

A *donation*, to be valid and complete, supposes a capacity both in the donor, and the donee; and requires consent, acceptance, and delivery; and by the French law requires also.

DONATION mortis causa, in *Law*, a disposition of property made by a person in his last sickness, who, apprehending his dissolution near, delivers, or causes to be delivered to another, the possession of any personal goods, to keep in case of his decease. If the donor dies, this gift needs not the consent of his executor; but it shall not prevail against creditors; and it is accompanied with this implied trust, that if the donor lives, the property shall revert to himself, being only given in prospect of death, or *mortis causa*. This method of *donation* seems to have been conveyed to us from the civil lawyers, who borrowed it from the Greeks. Ovidius, lib. xvi. ver. 8. and Euripides, Alceides, ver. 1020. See **BLACKSTONE**, vol. ii. p. 514.

DONATISTS, ancient schismatics in Africa, so denominated from their leader, Donatus.

They had their origin in the year 311, when, in the room of Miltiades, who died in that year, on his return to Rome, Circilian was elected bishop of Carthage, and consecrated without the concurrence of the Numidian bishops, by those of Africa alone; whom the people refused to acknowledge, and to whom they opposed M. Jovinianus; who, accordingly, was ordained by Donatus, bishop of Caste Nigra. They were condemned, in a council held at Rome, two years after their separation; and

afterwards in another at Arles, the year following; and again at Milan, before Constantine the Great, in 316, who deprived them of their churches, and sent their odious bishops into banishment, and punished some of them with death. Their cause was espoused by another Donatus, called the Great, the principal bishop of that sect, who, with numbers of his followers, was exiled by order of Constantine. Many of them were punished with great severity. See **CIRCUMCELLIONES**. However, after the accession of Julian to the throne, in 361, they were permitted to return, and restored to their former liberty.

Gratian published several edicts against them; and in 377 deprived them of their churches, and prohibited all their assemblies. But notwithstanding the severities they suffered, it appears that they had a very considerable number of churches towards the close of this century; but at this time they began to decline, on account of a schism among themselves, occasioned by the election of two bishops, in the room of Parmenian, the successor of Donatus; one party elected Primian, and were called Primianists, and another Maximian, and were called Maximianists. Their decline was also precipitated by the zealous opposition of St. Augustine, and by the violent measures which were pursued against them; by order of the emperor Honorius, at the solicitation of two councils held at Carthage; the one in 424, and the other in 431. Many of them were fined, their bishops were banished, and some put to death. This sect revived and multiplied under the protection of the Vandals who invaded Africa in 427, and took possession of this province; but it sunk again under new severities, when their empire was overthrown in 534. Nevertheless they remained in a separate body till the close of this century, when Gregory, the Roman pontiff, used various methods for suppressing them; his zeal succeeded, and there are few traces to be found of the *Donatists* after this period. They were distinguished by other appellations; as *Circumcelliones*, *Montanists*, or *Montanians*, *Campites*, *Rupites*, &c. They held three councils, or conciliabules; that of Citta in Numidia, and two at Carthage.

The errors of the *Donatists*, beside their schism, were, 1. That baptism conferred out of the church, that is, out of their sect, was null; and accordingly they rebaptized those who joined their party from other churches, and re-ordained their ministers. 2. That theirs was the only true, pure and holy church; all the rest of the churches they held as profane, and fallen.

Donatus seems likewise to have given into the doctrine of the Arians, with whom he was closely allied; and accordingly, St. Epiphanius, Theodoret, and some others, accused the *Donatists* of Arianism; and it is probable that the charge was well founded, because they were patronized by the Vandals, who were of their sentiments. But St. Augustine, ep. 185, to count Boniface, & Hier. 69, affirms, that the *Donatists*, in this point, kept clear of the errors of their leader.

DONATIVE, **DONATIVUM**, a present made to any person; called also *gratuity*.

The Romans made large *donatives* to their soldiers. Julia Pia, wife of the emperor Severus, is called, on certain medals, *MATER CAESTRORUM*, because of the care she took of the soldiery, by interposing for the augmentation of their *donatives*, &c.

Donative was properly a gift made to the soldiery; as **CONGIARIUM** was that made to the people. Salmastius, in his notes to Lampridius, in his Life of Heliogabalus, mentioning a *donative* that emperor gave of three pieces of gold per head, observes, that this was the common and legitimate use of a *donative*. Calaubon, in his notes on the Life of Pertinax by Capitolinus, observes, that Pertinax made a promise of three thousand denarii to each soldier; which amounts to upwards of ninety-seven pounds sterling. The same author writes, that the legal *donative* was twenty thousand denarii; and that it was not customary to give less, especially to the praetorian soldiers; that the centurions had double, and the tribunes, &c. more in proportion.

DONATIVE, in the *Canon Law*, a benefice given, and collated to a person, by the founder, or patron; without either presentation, institution, or induction by the ordinary.

If chapels founded by laymen be not approved by the diocesan, and, as it is called, *spiritualibus*, they are not accounted proper benefices, neither can they be conferred by the bishop, but remain to the private disposal of the founders; so that the founders, and their heirs, may give such chapels without the bishop.

Gwin observes, that the king might of ancient time found a free chapel, and exempt it from the jurisdiction of the diocesan; so may he, by letters patent, give liberty to a common person to found such a chapel, and make it *donative*, not presentable; and the chaplain, or beneficiary, shall be deprivable by the founder or his heirs, and not

not by the bishop. And this seems to be the original of *donatus* in England.

Donatus are within the statute against simony; and if they have cure of souls, within that against pluralities. If the patron of a *donatus* doth not nominate a clerk, there can be no lapse thereof, unless it be specially provided for in the foundation; but the bishop may compel him to do it by spiritual censures. But if it be augmented by queen Anne's bounty, it will lapse like other presentative livings. 1 Geo. I. stat. 2. cap. 10. The ordinary cannot visit a *donatus*, and therefore it is free from procurator, and the incumbent is exempted from attendance at visitations.

All bishopricks in ancient time were *donatus* by the king. Again, where the bishop has a gift of the benefice, it is properly called a *donatus*, because he cannot present to himself.

DONAX, in *Ichthyology*, a name by which several of the old authors have called the solen, or razor-fish. See **SOLE**.

DONAX, in *Botany*, the name by which some authors call the great reed, the arundo maximo, or arundo Cypria of others. Tourn. Inst. p. 256. See **REED**.

DONE *far, grant and render*, in *Law*, a double fine, comprehending the fine for *reignance de droit com-tes*, and the fine for *concessu*, which may be used to create particular limitations of estates. See **FINE**.

DONGON, in *Natural History*, a name given by the people of the Philippine islands to a peculiar species of crane, which has a large body like a goose, and a shorter neck than the common kind: it has a long and very broad beak, and is of a grey colour; they have, besides this, another species of crane, which they call *tipal* or *thoi*; as remarkable for the length of its neck and legs, as this for the breadth of its beak. This tipal can stand erect, and look over a tall man's head.

DONJON, in *Fortification*, generally denotes a large strong tower, or redoubt, of a fortress, where the garrison may retreat in case of necessity, and capitulate with greater advantage. See **DONJON**.

DONIS conditionalibus, fidei de, in *Law*, is the statute of Westminster 2. viz. 13 Edw. I. cap. 1. which revived in some sort the ancient feudal restraints, that were originally laid on alienations, by enacting, that from thenceforth the will of the donor be observed; and that the tenements so given, to a man, and the heirs of his body, should at all events go to the issue, if there were any; or, if none, should revert to the donor. Blackst. Com. vol. ii. p. 112.

DONNA, or *LA DONNA*, in *Ichthyology*, a name given by Zuccheri, and some other authors, to the manati, or *SEA-COW*.

DONOR, in *Law*, he who gives lands or tenements, to another, in tail. As donee, is he to whom the same are given.

DONZELLINA, in *Ichthyology*, a name by which some called the *july*, a very beautifully painted fish of the Mediterranean, approaching to the nature of the turbot or wrasse. See **JULY**.

DOOLS, a term used in several parts of the kingdom for balks, or slips of pasture, left between the furrows of ploughed lands.

DORR, in *Architecture*, an aperture in a wall, to give entrance, and exit, in and out of the building, or some apartment thereof. Mod. of the observations that are applicable to *WINDOWS* may be applied to *dors*.

The proportions of *dors* are adjusted by those of a man: in larger buildings they must always be larger than in smaller; but in none should they be less than six feet high, to admit a man of just stature, erect; and as the breadth of a man, with his arms placed a-kimbo, is nearly subdouble his height, the width should never be less than three feet.

Some architects give us these dimensions: in small buildings the breadth of the *dors* four feet, or four and a half; in middling buildings, five or six; in large ones, seven or eight; in chambers of the first, three, and a half, three quarters, or four; of the second, four, or four and a half; and of the third, five, or six; in churches seven, or eight; in gates, nine, ten, or twelve: hence their height is easily determined; except for the gates of cities, which should only be four fifths of their breadth.

It is an observation of Palladio, that the principal *dors*, or entrance, of a house, must never be regulated by any certain dimensions, but by the dignity of the person that is to live in it; yet, to exceed rather in the more, than the less, is a mark of generosity; and may be excused with some noble emblems, or inscription, as that of the count de Bevilacqua over his large gate at Verona, where had been committed a like disproportion, *Pater Janus, Rex magni*.

The principal *dors*, as it is the entrance into all the apart-

ments, should be in the centre of the edifice; though in small houses convenience may sometimes require its being placed on one side.

DOOR, *fenestration* of a. See **SCENOGRAPHY**.

DOOR, *architrave*. See **ARCHITRAVE**.

DOR, the English name for the common black beetle. Some also apply it to the dusty beetle, that flies about hedges in the evening. See **SCARABEUS**.

DORADO, in *Astronomy*, a southern constellation, not visible in our latitude; it is also called *XIPHIAS*. The stars of this constellation, in Sharp's Catalogue, are fix-

Names and situation of the Stars.	Right Ascension.	Long. rad.	Latitude.	Magnitude.
In the head	10 10 40 2 4 10			6
In the gills	11 10 27 37 33 40			6
In the belly	12 10 27 38 12 20 5			5
Above the back	18 33 28 35 4 23 4			4
In the tail	4 5 31 74 38 11 1 4			4
In the end of the tail	2 44 28 70 12 28 4			4

DORADO, in *Ichthyology*, the name of a large sea-fish, called by the Brazilians, *guaracapes*; and so much resembling the hippuris, as by many to be supposed to be the same fish; it grows to six or seven feet in length, and is of a somewhat broad and flattened form, being a foot and a half broad near the head; the head ends in a square, and is thinned away to an edge, for the advantage of the creature's swimming the more swiftly. Its mouth is but small for its size, and is furnished with very sharp teeth; its eyes are large and round, and placed but a little above its mouth; its gills are large. It has one long fin running the whole length of the back, and another answering it on the belly, reaching from the anus to the tail; the tail is long, large, and forked; its scales are very smooth, and scarce sensible to the touch; its head, back, and sides, are of a silver-green, its belly white; its back and sides are spotted with blue; it is a very swift fish in swimming, and is very delicate and well tasted.

DOREAS Lybie, in *Natural History*, the name by which Aelian and some other authors have called the common antelope. See **GAZELLA**.

DORRE, or *Jabu DORRE*, in *Ichthyology*, a name given by us to a fish, called by authors the *faber* and *gallus marinus*. We have borrowed the name *dorre* from the French; and, as to the word *Jabu*, by some writers prefixed to it, it seems only a corruption of the French word *jaune*, *yellow*; they expressing the colour of the scales of this fish, which is a gold-yellow, by the phrase *jaune dorre*; this has given us the words *Jabu Dorre*, or by those who spell yet worse, *Jabu Dory*, as we see it in some authors.

According to the new Artedean system, this is a species of the *zeus*, and is distinguished by that author from the others of that genus, by the name of the *zeus* with a prickly belly, and with a tail, not forked at the end, but rounded. Willoughby, Hist. Pisc. p. 295. See **ZEUS**.

It is a short and very broad and flat fish, being every where of the same thickness, and something approaching to the plate in figure, but swimming upright. Its head is large and very much flattened, its mouth extremely wide, and its eyes large. Its sides are of an olive colour, beautifully variegated with a bluish white; and in the middle of each side, there is one large black spot of the size of a silver two-pence. It has two fins on the back, the anterior is the higher, and has ten rigid spines, accompanied with softer and very large rays, which bend into the form of a reaper's sickle. The tail ends in a circular figure. Its usual size is from six to ten inches in length, and it is commonly nearly half as broad as long. See **TAB. V. FISH.** N° 67.

The flesh is well tasted, and by many preferred to that of the turbot. It is caught in the Mediterranean and other seas, and is not uncommon on the Cornwall coast, and other of the English shores.

The *Jabu DORRE* is a fish caught in many parts of the East Indies, and called by the Dutch there, the *meerbaer*, the same with the *abacatus* of Marggrave, caught in the Brazilian seas. See **ABACATUS**.

DORIA, in *Botany*. See **GOLDEN-ROD**.

DORIALTIDES, in *Natural History*, the name of a stone, to which great virtues, medicinal and magical, were attributed by the writers of the middle ages.

DORIAN, in *Antient Music*, the fourth species of the *DIA-PYCON*.

DORIC, in *Architecture*, is the second of the five orders; being that between the Tuscan and Ionic. It is usually placed

placed upon the Attic base, though originally it had no base.

The Doric order seems the most natural, and best proportioned, of all the orders; all its parts being founded on the natural position of solid bodies. Accordingly, the Doric is the first, and most ancient, of the orders of architecture; and is what gave the first idea of regular building. See *Tab. Archit. fig. 25*. See also ARCHITECTURE.

At its first invention it was more simple than at present; and when in after-times they came to adorn and enrich it more, the appellation Doric was restrained to this richer manner, and the primitive simple manner they called by a new name, the Tuscan order, which was chiefly used in temples; as the former, being more light and delicate, was for porticoes and theatres.

The tradition is, that Dorus, king of Achæa, having first built a temple of this order at Argos, which he dedicated to Juno, occasioned it to be called Doric; though others derive its name, from its being invented, or used by the Dorians.

Some time after its invention they reduced it to the proportions, strength, and beauty, of the body of a man; hence, as the foot of a man was judged the sixth part of his height, they made the Doric column, including the capital, six diameters high, i. e. six times as high as thick. Afterwards they added another diameter to the height, and made it seven diameters; with which augmentation it might be said to be nearer the proportion of a man; the human foot, at least in our days, not being a sixth, but nearly a seventh part of the body.

The characters of the Doric order, as now managed, are, the height of its column, which is eight diameters; its frieze, which is enriched with triglyphs, drops, and metopes; its capital, which is without volutes; and its admitting of cymatiums.

Vitruvius, indeed, complains of the Doric as very troublesome and perplexing, on account of the triglyphs and metopes, as far as to be capable of being used, except in the pycnostyle, by putting a triglyph between each two columns, or in the anastyle, by putting three triglyphs between each two columns.

The moderns, on account of its solidity, use it in large strong buildings; as in the gates of cities, and citadels, the outside of churches, and other massy works, where delicacy of ornaments would be unsuitable.

The gate of Burlington-house in Piccadilly, is of the Doric order.

The most considerable ancient monuments of this order, are the theatre of Marcellus, at Rome; wherein the capital, the height of the frieze, and its projection, are much smaller than in the modern architecture; and the Parthenon, or temple of Minerva, at Athens, in which the short and massy columns bear upon the pavement without a base; and the capital is a simple torus with its cincture, and a square, plain, and solid abacus.

Vignola adjusts the proportions of the Doric order thus: the whole height of the order, without pedestal, he divides into twenty parts, or modules; one of which he allows the base, fourteen to the shaft, or full, one to the capital, and four to the entablature.

The particular proportions, &c. of the several parts and members, see under their respective articles, ARCHITRAVE, BASE, CAPITAL, COLUMN, CORNICH, ENTABLATURE, FRIZE, and PÉDESTAL.

Doric Cymatium. See Cymatium.

Doric in Grammar. The Doric dialect is one of the five dialects, or manners of speaking, which obtained among the Greeks. See DIALECT.

It was first used by the Lacedæmonians, and particularly those of Argos; thence it passed into Epirus, Libya, Sicily, the islands of Rhodes, and Crete.

In this dialect, Archimedes and Theocritus wrote, who were both of Syracuse; as likewise Pindar.

In strictness, however, we should rather define Doric, the manner of speaking peculiar to the Dorians, after their recess near Parnassus, and Alopia; and which afterwards came to obtain among the Lacedæmonians, &c. Some even distinguish between the Lacedæmonian and Doric; but, in reality, they were the same; setting aside a few particularities in the language of the Lacedæmonians; as is shown by Rulandus, in his excellent treatise, *De Lingua Græca, ejusque Dialectis*, lib. v.

Beside the authors already mentioned to have written in the Doric dialect, we might add Archytas of Tarentum, Bion, Callinus, Simonides, Bacchylides, Cypselas, Alcman, and Sophron.

Most of the medals of the cities of Græcia Magna, and Sicily, favour of the Doric dialect in their inscriptions; witness, AMBAPKIDIAN, AΠΟΛΟΝΙΑΝ, ΑΧΕΡΟΝΤΑΝ, ΑΧΥΡΙΑΝ, ΗΡΑΚΛΕΙΑΝ, ΤΡΑΞΙΝΙΟΝ, ΟΡΕΜΙΤΑΝ, ΚΑΤΑΟΝΙΑΝ, ΚΟΝΙΑΝ, ΤΑΥΡΟ-

ΜΕΝΙΤΑΝ, &c. Which shews the countries wherein the Doric dialect was used.

The general rules of this dialect are thus given by the Post-royalists:

D's *Str.* *d'a grand, d'i, d'e, d'u l'a fait le Doric.*
D'u fait avec d'a, e, i, d'u au fait avec.
O's *de l'infinitif: & pour le singulier.*
Se fait au féminin du nombre pluriel.

But they are much better explained in the fourth book of Rulandus; where he even notes the minutest differences of the dialects of Sicily, Crete, Tarentum, Rhodes, Lacedæmon, Laconia, Macedonia, and Thibet.

The *a* abounds everywhere in the Doric; but this dialect bears no more a conformity with the *Æolic*, than many reckon them but one.

Doric, in Music. The Doric mode is the first of the authentic modes of the ancients.

Its character is, to be severe, tempered with gravity and mirth: it is proper for occasions of religion, and war. It begins with *D, Sol, Re*.

Plato admires the music of the Doric mode; and judges it proper, to preserve good manners, as being masculine. And on this account he allows of it in his Commonwealth.

The ancients had likewise the Sub-Doric mode, which was one of their plagal modes. Its character was, to be very grave, and solemn. It began with *G Ut*, a diatessaron lower than the Doric mode.

DORING, or DARING, among the Sportsmen, a term used to express a method of taking larks, by means of a CLAYNET, and a looking-glass. For this sport there must be provided four sticks, very straight and light, about the bigness of a pike; two of these are to be four feet nine inches long, and all notched at the edges, or at the end. At one end of each of these sticks there is to be fastened another of about a foot long on one side; and on the other side a small wooden peg, about three inches long. Then four more sticks are to be prepared, each of one foot length; and each of these must have a cord of nine feet long fastened to it at the end. Every one should have a buckle for the commodious fastening on to the respective sticks when the net is to be spread.

A cord must also be provided, which must have two branches. The one must be nine feet and a half, and the other ten feet long, with a buckle at the end of each; the rest or body of the cord must be twenty-four yards long. All these cords, as well the long ones as those about the sticks, must be well twisted, and of the bigness of one's little finger. The next thing to be provided is a staff of four feet long, pointed at one end, and with a ball of wood on the other, for carrying these conveniences in a sack or wallet.

There should also be carried, on this occasion, a spade to level the ground where there may be any little irregularities; and two small rods, each eighteen inches long, and having a small rod, fixed with a packthread at the larger end of the other. To these are to be tied some packthread loops, which are to fasten the legs of some larks; and there are to be reels to these, that these birds may fly a little way up and down.

When all this is done, the looking-glass is to be prepared in the following manner. Take a piece of wood, about an inch and a half thick, and cut it in form of a bow, so that there may be about nine inches space between the two ends; and let it have its full thickness at the bottom, that it may receive into it a false piece; in the five corners of which, there are to be let in five pieces of looking-glass. These are to be so fixed, that they may part their light upwards, and the whole machine is to be supported on a moveable pin, with the end of a long line fixed to it; and made in the manner of the children's play-thing of an apple and a plum-stone; so that the other end of the cord being carried through a hedge, the barely pulling it may set the whole machine of the glasses a-turning. This and the other contrivances are to be placed in the middle between the two nets. The larks fixed to the place, and termed calls, and the glittering of the looking-glasses, as they twist round in the sun, invite the other larks down; and the cord that communicates with the nets, and goes through the hedge, gives the person behind an opportunity of pulling up the nets, so as to meet over the whole, and to see nothing that is between them. The place where the nets of sporting succeeds, best are open fields, remote from any trees or hedges, except one by way of shelter to the sportsman, and the wind should always be either in the front or back; for if it blows sideways, it prevents the playing of the nets.

DORMANT, from *dormis*, *I sleep*, is the herald's term for the posture of a lion, or other beast, borne as sleeping in a coat of arms.

DORMANT-

DORMANT-tree, in *Building*, a name the workmen frequently give to a great beam lying across the house; usually called a *summer*.

DORMANT, or **DORMAR-tiles**. See **TYLE**.

DORMER, or **DORMANT**, in *Architecture*, denotes a window made in the roof of an house, or above the entablature; being raised upon the rafters.

* The Latins call it *lucerna*, whence the French *lucarne*, and our *luthern*.

There are diverse kinds; square, round, &c. See **LUTHERN**.

DORMITORY, a gallery in convents, or religious houses, divided into several cells, wherein the religious lodge, or lie, &c.

The word is formed from the Latin *dormitorium*; of *dormire*, to sleep.

It is deemed a crime in a religious to lie out of the *dormitory*. By chap. xxii. of the rule of St. Benedict, it appears, that the ancient *dormitories* were not divided into cells, but were a kind of large open wards, filled with beds, as in our hospitals.

DORMITORY is also used for a burying-place. See **COEMETERIUM**.

DORMOUSE, in *Zoology*, the name of a species of wild field-mouse, called also the sleeper, classed under the genus of *MOUSE*, in the order of *gires*, in the Linnæan system. It has two cutting-teeth in each jaw; four toes before, and five behind, and naked ears. There are two kinds of this creature, a larger and a smaller.

The larger *dormouse* is the *mus quercinus* of Linnæus, with a long hairy tail, and a black spot under the eyes, and nearly of the size of the common rat. Its colour is a brownish grey, like that of the common mouse, but variegated with somewhat of a reddish cast on the sides, and on the head; the tail is all over hairy, and is terminated by a thick tuft of white fur. The eyes are large and prominent, and of a fine jetty shining black. The beard is partly white, and partly black. Round about the eyes, and round the ears, there is a fine blackness; the upper part of the tail is also black. The smell of this creature is the same with that of the mouse, and its dung of the same kind. It lives in caverns under-ground, and sleeps the chief part of the winter. It feeds on vegetables, and is particularly fond of hazel-nuts, which it usually hoards up. It lodges in holes in the walls, and brings five or six young at a time; infests gardens; and is very destructive to fruits of all kinds.

The smaller kind is the *mus avellanarius* of Linnæus, with a long hairy tail, red body, and whitish throat, and is much more common than the larger one. This is of the size of the common mouse, and in different countries varies much in colour. In Italy, Mr. Ray observed it all over of a reddish tawney on the upper part, except the end of the tail, and its upper part white, the tail only excepted; the tail covered with long and thick-set hairs, and looking somewhat like a squirrel's. The eyes are very black and prominent. Those which the same author observed in England were less of the reddish hue on the back, and were not white under the belly, but only on the throat; neither had they the white tip at the end of the tail. Possibly the Italian and English may be really distinct species. This creature feeds on nuts, and other such fruits. It retires into caves in winter, rolls itself up, and sleeps much. It lives in thick hedges, forms its nest of dead leaves, moss, or grass, and brings three or four young at a time.

DORONICI radix, in the *Materia Medica*, the name of a root kept in the shops in some places, but at present little used. There are two kinds of it, the Roman and the German. The Roman is a small yellow root, appearing white when broken, of a sweet astringent taste, and viscid in the mouth. The fairest and plumpest roots should be chosen, and such as are fresh dried, or at least not worm-eaten. The root is brought from the Alps, and some other places. The plant which produces it is the *doronicum officinarum* of Gerard, and is kept with us in the gardens of the curious. The leaves are broad, and the flower is yellow, and of the size of a marigold.

It is said to be an alexipharmic, but is not used in the present practice. Authors are indeed not at all agreed about its nature; some accounting it a very valuable medicine, and others a poison.

The German *doronicum* is a native of the mountainous parts of Germany, and flowers through the summer. The leaves and flowers bruised, emit a light pungent smell, which provokes sneezing. They yield their virtues by infusion, both to water, and rectified spirit; the roots are more aromatic than the other parts. This plant has been esteemed in Germany as a specific for dissolving coagulated blood, occasioned by falls and bruises, and thence has been intitled *lupulinum panacea*. It

is likewise recommended in various obstinate chronic disorders; but its operation is too violent. Lewis's Mat. Med. p. 255. See **DURUNCU**.

DORONICUM, in *Botany*. See **LEOPARD'S BANE**.

DORSAL, from *dorsum*, back, any thing that belongs to the back; as *dorsal GLANDS*, *dorsal NERVES*, *dorsal MUSCLES*, &c.

DORSCH, in *Ichthyography*, the common name of a small fish of the cod-kind, frequent in the Baltic, but more rare in other seas, and called by authors the *stellus varius*, or *tristatus*. It is remarkable for having the smoothest and softest skin of all the cod-kind; nevertheless it has small scales. It is usually caught of a foot, or a little more, in length. It approaches nearest to the species called the whiting-pollack, but differs from it in having a beard. It is a fine fish for the table.

DORSI primus, in *Anatomy*, a name given by Fallopius, and many other authors, to a muscle, now generally known by the name of *quadratus lumborum*, or the external lumbar muscle. See **QUADRATUS**.

DORSI latissimus, in *Anatomy*. See **LATISSIMUS dorsi**.

DORSI longissimus, a muscle common to the loins, and the back. It rises from the upper part of the sacrum, ilium, and first vertebra of the loins; and in its beginning is confounded, if not the same, with the sacrospinarius. It runs upwards along the whole tract of the back, and is connected to every transverse process in its way; ending sometimes in the first vertebra of the back, and sometimes in the first of the neck. See **Tab. Anat. (Mys.)** fig. 7. n. 17. 17.

DORSI, scilicet. See **SACRA**.

DORSIFEROUS, or **DORSIPAROUS plants**, from *dorsum*, and *fero*, I bear, are those of the capillary kind; which are without stem, and bear their seeds on the backside of their leaves.

DORSTENIA, in *Botany*. See **CONTRAYERA**.

DORSUM, in *Anatomy*, is the hind part of the thorax; commonly translated the *back*.

The *dorsum* includes also the **LOINS**.

Dorsum manus, and *pedis*, is the outside of the hand and foot; or that part opposite to the palm and sole.

Dorsum nasi is the ridge of the nose, which runs the whole length of that part.

In those we call Roman noses, the *dorsum* is higher, and more prominent, about the middle, than in the rest; which part is called the *spina*, or *spine*.

DORT, *synod* of, in *Ecclesiastical History*, a national synod, summoned by authority of the states-general, the provinces of Holland, Utrecht, and Overijssel, excepted, and held at Dort in 1618. The most eminent divines of the United Provinces, and deputies from the churches of England, Scotland, Switzerland, Bremen, Hesse, and the Palatinate, assembled on this occasion, in order to decide the controversy between the GOMARISTS, or CALVINISTS, and ARMINIANS; the latter of whom were declared corrupters of the true religion. But the authority of this synod was far from being universally acknowledged either in Holland or in England. The provinces of Friesland, Zealand, Utrecht, Guelderland, and Groningen, could not be persuaded to adopt their decisions; and they were opposed by the authority of archbishop Laud, and king James I. in England. The reformed churches in France, though at first disposed to give a favourable reception to the decisions of this famous synod, in process of time espoused doctrines very different from those of the Gomarists; and the churches of Brandenburg and Bremen would not suffer their doctors to be tied down to the opinions and tenets of the Dutch divines. The liberty of private judgment, with respect to the doctrines of PREDESTINATION and GRACE, which the spirit that prevailed among the divines of Dort seemed so much adapted to discourage and suppress, acquired new vigour, in consequence of the arbitrary proceedings of this assembly. Moth. Eccl. Hist. vol. iv. p. 498. &c. 8vo ed.

DORTMANNIA, in *Botany*. See **LOBELIA**.

DORYCNium, in *Botany*, a name given by some to the upright unbelted silvery bindweed, called by others *cucurbit*. See **CONVOLVULUS**.

DORYDREPANON. See **DREPANON**.

DORYPHORI, from *dops*, spear, and *phoro*, I bear, an appellation given to the life-guard-men of the Roman emperors. They were held in such high estimation, as frequently to have the command of armies conferred on them.

It was usual also for chief commanders to have their *doryphori*, or life-guard, to attend them.

DOSE, in *Pharmacy*, &c. the quantity of a medicine to be taken at one time.

The word is formed from the Greek *dosis*, which signifies gift, or a thing given; from *didomi*, *dos* I give. A secret in physic is nothing, unless the *dose* be known.

In authors, and dispensatories, that describe the same remedy, frequently the *dose* is different; which occasions a great difference in its effect.

Dr. Coebern has given us an essay towards determining the *doses* of purgative medicines, on mechanical principles.

Several attempts have been made to ascertain the proportional *doses* for the different ages and constitutions of patients; but, after all that can be said on this subject, much must be left to the judgment of the person who administers the medicine. The following general proportions may be observed, though by no means intended for exact rules. A patient between 20 and 14 may take two-thirds of the *dose* ordered for an adult; from 14 to 9, one half; from 9 to 6, one third; from 6 to 4, one fourth; from 4 to 2, one sixth; from 2 to 1, a tenth; and under one, a twelfth. *Becham's Dom. Med. App.* p. 695.

DOSENS, fleight clothes made in Devonshire, and so called in *Rot. Parl.* 2 Hen. V. See **DOVEWEENS**.

DOSTITHEANS, **DOSTITHEI**, an ancient sect among the Samaritans, in the fifth century of the Christian era. Mention is made in Origen, Epiphanius, Jerom, and divers other Greek and Latin fathers, of one Dositheus, the chief of a faction among the Samaritans; but the learned are not all agreed as to the time wherein he lived. St. Jerom, in his dialogue against the Lucifarians, places him before our Saviour; wherein he is followed by Drusius, who, in his answer to Scetrazius, places him about the time of Scenacharib, king of Assyria; but Scaliger will have him posterior to our Saviour's time. And, in effect, Origen intimates him to have been contemporary with the apostles; where he observes, that he endeavoured to persuade the Samaritans, that he was the Messiah foretold by Moses.

He had many followers; and his sect was still subsisting at Alexandria in the time of the patriarch Eulogius; as appears from a decree of that patriarch, published by Photius. In that decree, Eulogius accuses Dositheus of injuriously treating the ancient patriarchs and prophets; and attributing to himself the spirit of prophecy. He makes him contemporary with Simon Magus; and accuses him of corrupting the Pentateuch in divers places, and of composing several books, directly contrary to the law of God.

Archbishop Usher takes Dositheus to be the author of all the changes made in the Samaritan Pentateuch; which he argues from the authority of Eulogius; but all we can justly gather from the testimony of Eulogius is, that Dositheus corrupted the Samaritan copies since used by that sect; but that corruption did not pass into all the copies of the Samaritan Pentateuch, now in use among us, which vary but little from the Jewish Pentateuch.

And in this sense we are to understand that passage in a Samaritan chronicle, where it is said, that Doula, i. e. Dositheus, altered several things in the law of Moses. The author of that chronicle, who was a Samaritan by religion, adds, that their high-priest sent several Samaritans to seize Doula, and his corrupted copy of the Pentateuch. Epiphanius takes him to have been a Jew by birth, and to have abandoned the Jewish party for that of the Samaritans. He imagines him likewise to have been the author of the sect of the Sadducees: this is inconsistent with his being later than our Saviour. And yet the Jesuit Scetrazius agrees to make Dositheus the master of Sadoc, from whom the Sadducees are derived.

Tertullian, making mention of the same Dositheus, observes, that he was the first who dared to reject the authority of the prophets, by denying their inspiration. But he charges that as a crime peculiar to this sectary, which, in reality, is common to the whole sect, who have never allowed any but the five books of Moses for divine.

DOSSER, a sort of basket to be carried on the shoulders of men. It is used in carrying the overplus earth from one part of a fortification to another, where it is wanted. There are like little carts and wheel-barrow for the same use.

DOSSEL, in Surgery, is lint made into a cylindric form, or resembling the shape of dates or olive stones. *Dossils* are sometimes secured by a thread tied round their middle. *Hist. Surgery*, *Introd.* sect. 53.

DOUL *vedi*. See **GOODS**.

DOULE *affigendi*, in Law, a writ that lay for a widow, where it was found by office, that the king's tenant was seized of tenements in fee, or fee-tail, at the day of his death; and that he held of the king in chief, &c. in which case, the widow came into the chancery, and there made oath, that she would not marry without the king's leave. *Ann. 1. Edw. III. c. 4.* And hereupon she had this writ to the chancery; for which fee Reg. of Writs, fol. 297. and *Fitz. Nat. Br.* fol. 263. These widows are called the king's widows.

DOLE unde nihil habet, in Law, a writ of dower that lies for the widow against the tenant, who bought land of her husband in his life time, whereof he was solely seized in fee-simple or fee-tail, in such sort, as the issue of them both might have inherited. *Fitz. Nat. Br.* fol. 147.

DOTS, *vide* *de*. See **RECTO**.

DOTS *administrati*. See **MEASUREMENT**, and **Reg. of writs, fol. 171.**

DOTTEREL, in Ornithology, the name by which the *marinella* is commonly known in most parts of England.

The usual weight of this bird is a quarter of a pound; but the male is smaller than the female, and weighs usually half an ounce less. Its beak is a finger's breadth long. Its head is very beautifully variegated with small black and white spots, and has a line of white over the eyes. Its throat is of a greyish white, variegated with streaks of brown. Its breast, and the under part of its wings, are of a dusky yellow. It is common in Lincolnshire, and some other counties of England; and is a very delicate bird. It is commonly caught in the night. *Ray's Ornith.* p. 230.

DOTTEREL, *Sua*, *Marinella* *TRINGA*, in the Linnean system, a name given by authors to the bird, commonly known in England by the name of the **TURNSTONE**; and called by Turner, *cinclus*. *Ray's Ornith.* p. 231.

DOTTO, in Natural History, a name given by some authors to a species of the emerald, which was a good green, but not clear or fine.

DOUBLE, in the *Mange*. A horse is said to double his reins, when he leaps several times together to throw the rider. Thus we say, this *raming* double his reins, and makes *posterior*. See **RAMINGUS**, and **POSTERIVIS**.

A hare is said to double when he keeps the plain fields, and winds about to deceive the hounds. *Dick. Rust.*

DOUBLE *Affect*. See **AFFECT**.

DOUBLE-banked, in Sea-language, denotes the situation of the oars of a boat, when two opposite ones are managed by rowers seated on the same bench, or thwart. The oars are also said to be double-banked when two men row upon every single one.

DOUBLE *Bastion*. See **BASTION**.

DOUBLE *Cast*, in Husbandry, a term used by the farmers for that method of sowing which does not dispense the necessary quantity of seed for a piece of land at one bout, but requires the going over it twice. *Ploet. Oxf.* p. 251.

DOUBLE *Children*, **DOUBLE** *Cats*, **DOUBLE** *Pears*, &c. instances of, are frequent in the Philosophical Transactions, and elsewhere. See **MONSTERS**.

Sir John Floyer, in the same Transactions, giving an account of a double turkey, furnishes some reflections on the production of double animals in general. Two turkeys, he relates, were taken out of an egg of the common size, when the rest were all hatched, which grew together by the flesh of the breast-bone; but, in all other parts, were distinct. They seemed less than the ordinary size, as wanting bulk, nutriment, and room for their growth, which latter, too, was apparently the occasion of their cohabitation.

For, having two distinct cavities in their bodies, and two hearts, they must have arisen from two oviducts; and consequently, the egg had two yolks, which is no uncommon accident. He had a dried double chicken: he assures us, that though it had four legs, four wings, &c. it had but one cavity in the body, one heart, and one head; and that this, consequently, was produced from one oviduct.

So, *Parvus* mentions a double infant with only one heart: in which case, the original, or flamen of the infant, was one, and the vessels regular: only the nerves and arteries towards the extremities, dividing into more branches than ordinary, produced those double parts. The same is the case in the double flowers of plants, occasioned by the richness of the soil. So it is in the eggs of quadrupeds, &c.

There are, therefore, two reasons of duplicity in embryos: 1. The conjoining, or connexion of two perfect animals; and, 2. An extraordinary division, and ramification of the original vessels, nerves, arteries, &c.

DOUBLE *Convex*, and **DOUBLE** *Convex Glass*. See **CONCAVE**, **CONVEX**, and **GLASS**.

DOUBLE *Conv*. See **CONV**.

DOUBLE *Dancette*, in Heraldry. See **DANCETTE**.

DOUBLE *Dekant*, in Music. See **DEKANT**.

DOUBLE *Horizontal Dial*, one with a double gnomon, which of one point out the hour on the outward circle, and the other shows the hour on the stereographic projection drawn upon it. This dial finds the meridian, hour, the sun's place, rising, setting, &c. and many other preparations of the globe. See **DIAL**.

DOUBLE *Disip*. See **DISIP**.

DOUBLE *Excentricity*. See **EXCENTRICITY**.

DOUBLE *Fisht*. See **FISHT**.

DOUBLE *Fever*. See **FEVER**.

DOUBLE FISH, or **DOUBLE FISHY**, in *Heraldry*. A cross is denominated *double fish*, when the extremities are pointed at each angle; that is, when each extremity has two points: in contradistinction to *fish*, where the extremity is sharpened away to one point.

Gibbon expresses it by an octagonal cross, the two points whereof at each extremity are parted inwards by a small space of a line; by which it is distinguished from the cross of Malta, the two points whereof proceed from a third point, or acute angle between them.

DOUBLE FINE. See **FINE**.

DOUBLE FUGUE. See **FUGUE**.

DOUBLE LUGG, in *Navigation*. See **TWELADE**.

DOUBLE LETTER, in *Grammar*, a letter, which has the force and effect of two; as the Hebrew *Tzaddi*, which is equivalent to *T* and *S*, or the Greek ξ , or Latin *x*, &c.

These letters are evidently equal to two; when we pronounce the Latin *axi*, or the English *axillary*, we give the *x* the same sound, as if it were written with two *ae*, *axiis*, *axillaryis*, or *ae* and *i*, *axiiis*, *axillaryis*. The Greeks have three, *Z*, *E*, *T*; the Latins only two, *X* and *Z*; and most of the modern languages have the same.

DOUBLE MEASURE. See **MEASURE**.

DOUBLE PEDESTAL. See **PEDESTAL**.

DOUBLE PLEA, in *Law*, is where the defendant alleges for himself two several matters in bar of the action; whereof either is sufficient to effect his desire, in debarring the plaintiff.

This is not admitted in common law: for which reason it is to be well observed, when a plea is *double*, and when not: for if a man alleges several matters, one not at all dependent on another, the plea is accounted *double*; but if they be mutually depending on each other, then it is accounted but *single*.

DOUBLE PLOUGH. See **PLOUGH**.

DOUBLE POINT, in the *Higher Geometry*. When all the right lines tending the same way with the infinite leg of any curve, do cut it only in one point (as happens in the ordinates of the Cartesian, and the cubical parabola); and in the right lines which are parallel to the asymptotes of hyperbolas, and parabolas, then you are to conceive, that these right lines pass through two other points of the curve, placed as it may be said, at an infinite distance. Which coincident intersection, whether it be a finite, or an infinite distance, Sir Isaac Newton calls the *double point*.

DOUBLE POSITION. See **POSITION**.

DOUBLE QUARTER, *Doubles quarto*, a complaint made by a clerk, or other, to the archbishop of the province, against an inferior ordinary, for delaying justice in some ecclesiastical cause; as to give sentence, institute a clerk presented, or the like.

Its denomination seems owing to this, that it is commonly made both against the judge, and him at whose suit justice is delayed.

DOUBLE RAISE. See **RAISE**.

DOUBLE ROAD. See **ROAD**.

DOUBLE TENAILL. See **TENAILL**.

DOUBLE TIME. See **TIME**.

DOUBLE TONGUE, in *Botany*, a name sometimes given to the BUTCHER'S BREAST, and GERANIUM.

DOUBLE VAULT. See **VAULT**.

DOUBLE VESSEL, in *Chemistry*, is when the neck of one bottle-head, or matrass, is put, and well luted, into the neck of another.

Of these there are divers kinds and forms, used in the circulation of spirits, in order to their being exalted, and refined, as high as can be. See **CIRCULATION**.

DOUBLE WHINNED PLOUGH. See **PLOUGH**.

DOUBLE WHINNED STAIRS. See **STAIRS**.

DOUBLE INCISION, grafting by. See **ENGRAFTING**.

DOUBLE WANCHER, recovery with. See **RECOVERY**.

DOUBLED COLUMN. See **COLUMN**.

DOUBLES, in our *Statute*, signify as much as letters patent, being a French word made of the Latin *diploma*. Anno Hen. VI. cap. 6.

DOUBLETS, among *Lapidaries*, denote crystals wrought into such a form, and so coloured, that the surfaces of two pieces thus coloured being laid together, might produce the same effect as if the whole substance of the crystal had been tinged. For this purpose, two plates of crystal must be cut in the manner of a brilliant, and fired so exactly, that no division can appear when they are laid together. The upper part must be polished ready for setting, and then the colours may be put between them by the following process: take of Venice, or Cyprus turpentine, two scruples, and add to it one scruple of the grains of pure malis powdered. Melt them together in a silver or brass spoon ladle, or other vessel, and mix with them any of the coloured substance proposed, well powdered. Warm the *doublets* to the same degree of heat with the mixture, and paint the upper surface of the lower part, and put the upper one

instantly upon it, pressing them evenly together. When the cement is quite cold, scrape the edges, and let the *doublets* be skillfully set, by carrying the mounting over the joint, so that the two pieces may be well secured from separating. The colour of the ruby may be imitated, by mixing a fourth part of carmine with fine crimson lake; the sapphire and amethyst may be counterfeited by mixing very bright Prussian blue with a small quantity of crimson lake; the emerald may be imitated by distilled verdigris, with a little powdered aloes; the garnet may be counterfeited by dragon's blood, the brightness of which may be improved by the addition of a small quantity of carmine; the yellow topazes may be imitated by mixing the powdered aloes with a little dragon's blood. Glais may be also prepared in the same manner.

Doublets may be easily distinguished, by holding them between the eye and the light, in such position, that the light may pass through the upper part and corner of the stone; which will then show such parts to be white, and that there is no colour in the body of the stone. Handmaid to the Arts, vol. II. p. 328, &c.

DOUBLINGS, in *Heraldry*, the things of robes, or mantles of state; or of the mantling in achievements.

DOUBLING, in a *Military Sense, is the putting of two ranks, or files of soldiers, into one.*

When the word of command is, *double your ranks*, then the second, fourth, and sixth ranks are to march up into the first, third, and fifth; so that of six ranks they make but three, leaving double the interval there was between them before. But it is not so when they *double the half file*, because then three ranks stand together, and the three others come up to *double* them; that is, the first, second, and third, are *doubled* by the fourth, fifth, and sixth; or on the contrary.

Double your file, directs each to march to that next to it on the right or left, according to the word of command; in which case the six ranks are turned into twelve, the men standing twelve deep; the distance between the files being now *double* of what it was before.

DOUBLING A CAPE, or *Point*, in *Navigation*, signifies the coming up with it, passing by it, and leaving it behind the ship.

The Portuguese pretend to be the first that ever *doubled* the Cape of Good Hope, under their admiral Vazquez de Gama; but we have accounts in history, particularly in Herodotus, of the Egyptians, Carthaginians, &c. having done the same long before them.

DOUBLING-NAIL, among *Shipwrights*, are the nails commonly used to fasten the lining of the gun-ports, &c.

DOUBLING-UPON, in a *Naval Engagement*, is the art of enclosing any part of a hostile fleet between two fires, or of cannonading it on both sides. It is usually performed by the van or rear of that fleet which is superior in number taking the advantage of the wind, or of its situation, and tacking, or veering round the van or rear of the enemy, who are thereby exposed to great danger, and can scarcely avoid being thrown into a general confusion.

DOUBLON, **DUBLON**, a Spanish and Portuguese coin, being the *double* of a pistole. See **PISTOLE** and **COIN**.

There are also *double talions* formerly current among us for three pounds twelve shillings.

DOUBTING, the act of withholding a full assent from any proposition; on suspicion, that we are not thoroughly apprised of the merits thereof; or from our not being able peremptorily to decide between the reasons for, and against it.

The Sceptics and Academics *doubt* of every thing; the character of their philosophy is, not to allow any thing for truth; but to withhold the assent, and keep the mind free, and in suspense. See **SCPTICS**.

The Epicureans trust their senses, and *doubt* of their reason: their leading principle is, that our senses always tell truth; that they are the first and only criterions of truth; and that if you go ever so little from them, you come within the proper province of *doubting*.

The Cartesian, on the contrary, of all things bid us *doubt* our senses; they are perpetually inculcating the deceitfulness of our senses; and tell us, that we are to *doubt* of every one of their reports, till they have been examined, and confirmed by reason. See **CARTESIAN**.

DOUBTING, in *Rhetoric*, a figure wherein the orator appears some time fluctuating, and undetermined what to do, or say. See **APORIA** and **DIAPORESIS**.

Tacitus furnishes us with an instance of *doubting*, almost to a degree of distraction, in those words of Tiberius, written to the senate: *Quid scribam, P. S. aut quomodo scribam, aut quid omnia non scribam hoc tempore, dii me dumque prius perant quam perire quidam sentio, si sis*.

DOUCETS, or **DOUCERS**, among *Sportsmen*, denote the testes of a deer or stag. Dict. Rust.

DOUCINE,

DOUCINE, in *Architecture*, a moulding, or ornament, on the highest part of the corniche, in form of a wave, half convex, and half concave. See *Tab. Archit. fig. 8*.

The *doucine* is the same with a *symistum*, or *gala*. See *Cymatium*, and *Gula recta*, and *inversa*.

DOVE, in *Ornithology*. See *PIGEON*.

Doves, ring, in *Ornithology*, the name of a bird of the pigeon kind, called by Aldrovand, and other authors, the *palmatus torquatus*, and by the Greeks *phafsa*. Its beak is yellow, its feet naked and red, its legs feathered almost down to the feet. The head, back, and coverts of the wings, are of a bluish ash-colour; the lower side of the neck and breast are of a purplish red, dashed with ash-colour. The upper part of its neck has a very regular and beautiful white circle, from which the bird has its name: and its whole neck, above and below this, is beautifully variegated with changes of colours, according as it is exposed to the light. The belly is of a dirty white, the greater quill feathers are dusky, the rest ash-coloured; underneath the ballard wing is a white stroke, pointing downwards. It is the largest pigeon we have, and may be distinguished by its size. It seldom flies single, but in large flocks, and builds on trees: its food is ivy-berries, and other vegetable matter. They begin to coo in March, when they pair, and leave off in the beginning of winter. See *Tab. of Birds*, N^o 13.

Dove, *turtur*, in *Ornithology*, a very beautiful little bird of the pigeon kind. The head, neck, and back, are of the bluish grey colour of the common pigeon, with some mixture of a reddish brown near the rump, and the bottom of the neck. Its belly is white; but its breast and throat of a fine bright purple, having the verge of each feather yellow; and the sides of the neck are variegated with a sort of tinglet of beautiful white feathers, with black bases. The tail is about three inches and a half long, having the two middlemost feathers of a dusky brown, and the others black, with white tips; and the end and exterior side of the outmost feathers wholly white. The weight of this bird is about four ounces. It feeds on hemp-seed, and other vegetable matters. It is remarkably shy, and breeds in thick woods, generally of oak.

Dove, *foa-turtile*, or *Grassland-dove*, in *Ornithology*, is a species of the *DIVER*, or the *COLUMBUS gryllis* of Linnaeus. The bill is an inch and a half long; straight, slender, and black; on each wing is a large bed of white, which in young birds is spotted; the tips of the lesser quill-feathers, and the inner coverts of the wings, are white; except these the whole plumage is black. In winter it is said to change to white; and a variety, spotted with black and white, is not uncommon in Scotland. The tail consists of twelve feathers; and the legs are red. These birds always keep at sea, except in breeding time, and they are shot with great difficulty, because they dive at the flash of the gun. The Welch call this bird *cas-gallangor*, or the sailor's hatred, from a notion that its appearance forebodes a storm. It visits St. Kilda's isle in March, makes its nest far under ground, and lays a grey egg, or, as some say, a whitish egg, spotted with rust, and speckled with ash colour.

Dove's foot, in *Botany*. See *GERANIUM*.

Dove-tail, in *Carpentry*, the strongest of all the kinds of jointings; wherein the tenon, or piece of wood that enters the other, goes widening to the extreme, and so cannot be drawn out again, because the tip, or extreme, is bigger than the whole.

It has its denomination from the resemblance the tenon bears to a *dove's* tail. The French call it *queue d'aronde*, *foolke's* tail; which name the English themselves also retain in fortification.

DOVILLA, in *Ichthyology*, a name given by the Massilians to the fish called the *dovellina* by the Italians; it is the *julia*, or *jalla*, of authors; and, according to the Artian system, it is a species of the *labrus*. That author distinguishes it by the name of the *labrus* of variegated colour, with two large teeth in the upper jaw. See *LABRUS*.

DOULEIA, Δουλεία, among the Athenians, a kind of punishment, by which the criminal was reduced into the condition of a slave. It was never inflicted upon any but the *arctus*, *journeurs*, and *freed servants*. Potter's *Archaeol. Graec.* lib. 1. cap. 25. tom. i. p. 130.

TO DOUSE, in *Sea Language*, is to lower suddenly, or slacken; and it is applied to a sail in a squall of wind, an extended hawser, &c.

DOWAGER, *Dotiara* (q. d. a widow *endowed*, or that has a jointure), a title, or addition, applied to the widows of princes, dukes, earls, and persons of high rank only.

DOWAGER, *quæra*. See *QUEEN*.

DOWER, *Dotarium*, *Dotarium*, or *Dos*, a portion of lands, or tenelements, which a widow enjoys for term

of life, from her husband, in case she survives him; and which, at her death, descends to their children. But she must have been the wife of the party at the time of his decease; or not divorced a *vinculo matrimonii*; nor, if she has eloped from her husband, and lives with an adulterer, shall she be entitled to *dower*, unless her husband be voluntarily reconciled to her. The widows of traitors are also barred of their *dower* by 5 and 6 Ed. VI. cap. 11. but not the widows of felons. An alien cannot be endowed, unless she be queen-consort. And if a woman levies a fine with her husband, or if a common recovery be had with the husband and wife of the husband's lands, she is barred of her *dower*. A widow, clear of these impediments, is by law entitled to be endowed of all lands and tenelements, of which her husband was seised in fee-simple or fee-tail at any time during the coverture; and of which any issue she might have had, might by possibility have been heir. See *JOINTURE*. Our law-books distinguish five kinds of *dower*; viz. *dower per legem communem*; per *consuetudinem*; ex *assensu patris et filii*; ex *assensu ecclesie*; and *de la plus belle*. But the two first are now only in use.

DOWER by the common law is a third part of such lands as the husband was sole seised of in fee during the marriage; which the wife is to enjoy during her life, and for which there lies a writ of *error*.

DOWER by custom gives the wife, in some places, half her husband's lands, so long as she lives single, as in gavel-kind. And as custom may enlarge, so that the widow may have the whole during life, which is called her *free bench*, so may it abridge, *dower*, and restrain it to a fourth part.

In DOWER ex assensu patris, et ad assensu ecclesie, the wife may have so much *dower* as shall be assigned, or agreed upon; but it ought not to exceed the third part of the husband's lands. If this be done before marriage, it is called a *jointure*.

DOWER de la plus belle. By this she is endowed with the best and best part of her husband's estate.

DOWER, *admeasurement of*. See *ADMEASUREMENT*.

DOWER, *assignment of*. See *ASSIGNMENT*.

DOWER, *tenant in*. See *TENANT*.

DOWLE and DEAL, in our *Old Writers*, are used to signify a division. The word comes from the Saxon *dal*, i. e. *divisio*, and that from *dealan*, *dividere*; whence our English word *dealing* is formed.

In this sense it is, that the stones laid to the boundaries of lands are called *devising-stones*.

DOWN, in *Natural History*, denotes the first feathers of geese, with which beds and pillows are stuffed. The cottony substance on the tops of thistles, &c. is also thus called.

DOWNs, a bank, or elevation, of sand, which the sea gathers and forms along its shores; and which serves as a barrier.

The word is formed from the French *dune*, of the Celtic *dum*, a mountain. Charles de Vilch. in his *Compend. Chronolog. Exord.* & *Progress.* Abbat. Clariss. B. Maritz, de Dunis, says, *Vallem reperit arenarum collibus (quos joculari Duynen vocant) undique circumlatum*.

DOWNs are particularly used for a famous road for ships, along the eastern coast of the county of Kent; from Dover to the North Foreland.

This road has excellent anchorage, and is well defended by the castles of Sandwich, Deal, and Dover. Here it is the English fleets usually meet.

DOWNy, something partaking of the nature of *dowse*. Thus some leaves and fruits, &c. are said to be covered with a *dowse* matter.

DOWRY, *Dos*, is properly the money, or fortune, which the wife brings her husband in marriage, to have the use of, during her marriage, towards supporting the charge thereof.

It is otherwise called *matrimonium*, *marriage pendi*; by the Romans; *dos*; and it differs from *dower*. See *DOWER*.

Among the Germans, it was anciently customary for the husband to bring a *dowry* to his wife. *Romani non in usu suis nuptibus dotes retinebant; idcirco verba exquirunt quæ dotes significaret; et rem ipsam in Germanorum moribus præter Tacitum: docemur, inquit, non uxori mariti, sed uxori maritus offerri.* Spelman.

DOWRY is also used, in a monastic sense, for a sum of money given along with a maid, upon entering her in some religious order.

In France, the *dowry* of persons entering a monastery, to make profession of a religious life, is limited by law. *Char. e. gr.* given upon entering a monastery of Carmelites, Ursulines, and others, not regularly founded, but established since the year 1600, by letters patent, must not exceed the sum of 8000 livres, in towns where parliaments are held; nor 6000, in other places.

DOWSEINES, a sort of kerseys made in Devonshire, in length

length twelve yards; whence also their name, which is otherwise writ *denari*, or *denarii*.

DOXOLOGY, an appellation given by the Greeks to the fourteenth verse of the second chapter of St. Luke, *Gloria to God in the highest*, &c. because beginning with the Greek word *δοξα*, glory.

This they distinguish by the name of *great doxology*; and the *Gloria Patri*, *Gloria to the Father*, they call the *less doxology*, as beginning with the same word *δοξα*.

Philostorgius, lib. iii. c. 13. gives three formulas of the *less doxology*. The first is, *Gloria to the Father, and to the Son, and to the Holy Ghost*; the second, *Gloria to the Father, to the Son, in the Holy Ghost*; and the third, *Gloria to the Father, in the Son, and the Holy Ghost*.

Sozomen, and Nicephorus, give a fourth; viz. *Gloria to the Father, and the Son, in the Holy Ghost*.

The first of these *doxologies* is that in common use throughout the western church. It was first introduced about the year 320, by the Catholics of Antioch, then called *Eusebians*.

The three others were composed by the Arians; the second was that of Eusebius, and Eudoxus, and which was approved by Philostorgius. The three were all made about the year 341, in the council of Antioch, when they first began to disagree among themselves. Philostorgius assures us, that Flavian, afterward patriarch of Antioch, was the author of the first, or *catholic doxology*; but Sozomen, and Theodoret, say nothing of it; and Philostorgius's single authority is hardly sufficient.

There were anciently very great disputes, and principally at Antioch, as to the form of *doxology*; that mostly used among the orthodox was, the same as still obtains; the rest were affected by the Arians, and other Antrinitarians; yet St. Basil, in his book on the Holy Spirit, defends the second as orthodox, and legitimate; and it is certainly more agreeable to Scripture authority; to which we must ultimately appeal, as the only infallible rule of our devotion, as well as of our conduct; and it has been urged, that no influence of the former *doxology* occurs in the New Testament.

Some authors write hymnology as synonymous with *doxology*; but there is a difference: hymnology is applied to Psalms, or the recitation of Psalms; and *doxology* only to the little verse, *Gloria to the Father*, &c. repeated at the end of each Psalm.

DOZEIN, *Dozeina*. In the statute for view of frankpledge, made 18 Edw. II. one of the articles for stewards in their leets to enquire of, is, if all the *dozeins* be in the shire of our lord the king, and which not, and who received them. Art. 3. See **DECIPHER**.

DOZEIN is also used for a sort of Devonshire kerseys. Anno 6 Edw. VI. cap. 6. See **DOZEIN**.

DOZELLINA, in Ichthyology, a name by which some authors have called the mussels of the common species, which we in English term the *fish-shell*, and *whiffle-shell*.

DRABA, in Botany, *Helleborus*, a genus of the *tetradynamia singuliflora* class. Its characters are these: the flower hath four perals, in form of a cross, and six stamina, four of which are as long as the encephalon. In the centre it stands a bifid pecten, which afterward becomes an oblong, oval, entire pod, with two cells, furnished by the swelling style, which is oblique. The valves are parallel to the middle, and open oblique, each cell containing a single seed. There are eight species. See **DIETANDER**.

DRABLER, in the Sea-Language, a small sail in a ship, which is the same to a bonnet, that a bonnet is to a course, and is only used when the course and bonnet are too small to chase the mail. See **BOONET**, and **COURSE**.

DRABS, in the English Salt-works, a name given to a sort of wooden casks in which the salt is put, as soon as it is taken out of the boiling-pan. These are partitioned like flasks made for horres; they are lined on three sides and at the bottom with boards, and at the front have a sliding-board to put in or take out occasionally. Their bottoms are made sheathing, being highest at the back-side, and gradually inclining forwards; by which means the saline liquor that remains mixed with the salt easily drains out from it, and the salt in three or four days becomes sufficiently dry, and is then taken out and laid up in large heaps for sale. In some places they use cribs instead of the *drabs*. See **CRIAB**.

DRAECENA, in Botany, a genus of the *hexandria monogamia* class: the corolla is erect, and divided into six segments; the filaments are thickest in the middle, and the pistil is a three-celled berry, containing a single seed. There are five species.

DRAECENA, in Zoology, is also the name of a species of American lizard.

DRACHM, *Drachm*, an ancient silver coin, used among the Greeks. See **COIN**.

This they divided into six *obols*; and their larger coins above the *drachm* were the *di-drachm*, *tri-drachm*, and *tetra-*
VOL. II. N° 162.

drachm, or *statr*. The *drachm* was likewise a weight as well as a piece of money; and their *mina* contained a hundred *drachms*, both as a sum and a weight; and their talent sixty *mina*, or six thousand *drachms*, both by weight and tale; and this method of reckoning was common to all Greece; so that if the *drachms* of one city differed from that of another, their talents differed in the same proportion. The Attic *drachm* has been supposed by most authors, before Greaves, who first suggested the contrary, to have been the same, among the Greeks, with the *denarius*, among the Romans; which was equivalent to four sesterces. Of this opinion is Budaeus, De Affe; who confirms it from the authorities of Pliny, Plutarch, Strabo, and Valerius Maximus, with whom *spargus* is synonymous with *denarius*. Plin. Nat. Hist. lib. xxi. fn.

A. Grilius, who resided long at Athens, and could not be ignorant of the value of the current money of that city, says, that ten thousand *drachms* were in Roman money many *denarii*. Lib. i. cap. 8. See also Val. Maxim. lib. vii. cap. 6. and Strabo Geog. lib. v. the former of whom writes, that a certain commodity was sold for two hundred *denarii*; and the latter, in speaking of the same thing, says, that it was bought for two hundred *drachms*. But this is no strong confirmation, that the two coins were precisely of the same value; these authors, not treating expressly of coins, might easily render the one for the other, provided there were no considerable difference between them. Greaves's Misc. Works, by Birch, vol. i. p. 287, &c. 8vo.

Scaliger, in his dissertation, De Re Nummaria, does not say absolutely that the *denarius* and *drachm* were the same thing; but from a Greek passage in an ancient law, c. xxvi. *Mandati*, where the *drachm* is said to be composed of six *obols*, he concludes, that in the age of Severus, at least, they were the same. But Agricola, De Mens. & Ponder. lib. xiv. shews, from Pliny, Celsus, and Scribonius Largus, that the *denarius* contained only seven uncies; and from Livy, Appian, Cleopatra, &c. that the *drachm* contained eight; and maintains, that when some Greek authors speak of the ounce as only containing seven *drachms*, that they do not mean the Attic *drachm*, but the Roman *denarius*, which Greek authors render by *spargus*. We learn from Galen, that the writers on weights and measures differed in the number of *drachms* or *denarii*, which they assigned to an ounce; most of them making it to contain seven and a half, some but seven, and others eight. De Med. Comp. sec. Genera, lib. iii. cap. 3.

Gronovius agrees with Agricola, that the *drachm* was the eighth part of an ounce; and the opinion is confirmed by Isidore, lib. xiv. cap. 24. by Fannius, who says as much in express terms, and by Volusian, who divides the ounce into twenty-four *scrupuli*, or scruples, of which the *drachm* comprehended three.

It is probable, that when the Romans became masters of Greece and Asia, the Athenians might find it their interest to lower their *drachm* to the weight of their *denarius*, long before they were reduced into the form of a Roman province by Nespasian. When they did this is uncertain; but it appears by the treaty between the Romans and Antiochus, recorded by Polybius, Excerpt. Leg. sect. 35. and by Livy, lib. xxxviii. cap. 38. which states the Euboic talent to eighty Roman pounds; and supposing this to be equal to the Attic, and to contain six thousand Attic *drachms*, and eighty Roman pounds to contain six thousand seven hundred and twenty *denarii*, that the weight of the Attic *drachm* must have been to that of the *denarius* as 6720 to 6000; and this proportion is confirmed by an anonymous Greek fragment, published by Montfaucon, which makes a hundred Attic *drachms* equal to a hundred and twelve *denarii*. Anal. Græc. p. 393. Paris. 1688.

Greaves concludes, after weighing a number of Attic *tetradrachms*, and finding the weight of the *tetradrachm* at two hundred and sixty-eight grains, that the Attic *drachm* was sixty-seven grains. J. Caspar Eilenschmidt, in his book De Pond. & Mens. Vet. from an ancient *tetradrachm* weighing three hundred and thirty-three Paris grains, and by estimating the proportion between the Roman pound and Attic talent, mentioned by Livy, lib. xxviii. makes the *drachm* 83½ Paris grains, or almost 68½ Troy.

Mr. Raper has estimated the weight of the Attic *drachm*, by comparing it with the gold coins of Philip and Alexander, which were probably formed upon that standard. They both coined gold of 4, 2, 1, and ½ an Attic *drachm*; and from a mean of twenty-one Philipics, which were equivalent to two *drachms*, preferred in the British Museum, and in private collections, or mentioned by other writers, he infers, that the standard weight of the Philipic was not less than 133 Troy grains; which agrees
2 Q very

very nearly with the weights of some preserved silver *drachms* of Philip and Alexander, and with the mean weight of seven perfect silver *tetradrachms* of Alexander, which give a *drachm* a little more than 1324 grains. He observes, that the gold *Philipics*, both of Alexander and his father, are so correctly sized, and so perfect, that the mean *drachm*, derived from them of 133 troy grains, must be very near its just weight, and its half, 66½ grains, that of the Attic *drachm*. Then, for the value of it, as sixty-two English shillings are coined out of eleven ounces two penny-weight troy, of fine silver, and eighteen penny-weight of alloy, the troy grain of fine silver is worth $\frac{1}{60}$ of a farthing; and since the Greeks and Romans used no alloy in their money, but esteemed what they coined to be fine silver, the Attic *drachm* of 66½ grains will be found worth a little more than 91d. or, for the ease of reduction,

The Attic *drachm* may be
 rated at $\left. \begin{array}{l} \text{L. s. d.} \\ 0 \text{ } 0 \text{ } 9.286 \end{array} \right\}$
 The *shekel* a little more than $0 \text{ } 0 \text{ } 1$
 The *shekel* about $0 \text{ } 0 \text{ } 1$ of a farthing
 The *mina* $3 \text{ } 17 \text{ } 4.6$ of L. s. d.
 The *talent* $232 \text{ } 3 \text{ } 0$ of L. s. d.

Phil. Trans. vol. lxi. part ii. art. 48.
 Others estimating the ancient Roman ounce equal to the modern one, or to 536 French grains and the Attic *drachm* at 67 grains, and supposing the silver at Athens of the same fineness with ours, make it equal to 7 pence 2 sterling. See COIN.

DRACHM, or DRAM, is also a weight used by our physicians containing just sixty grains, or three scruples, or the eighth part of an ounce troy, and the sixteenth of an ounce avoirdupois.

DRACHM was likewise an ancient Jewish money; having on one side a harp, and on the other side a bunch of grapes.

This coin was a half shekel; and was so called by the Jews. It is only the Greeks called it *stater*. It was equal to two Attic *drachms*. See SHEKEL.

DRACO, DRAGON, in *Astronomy*, a constellation of the northern hemisphere; whose stars, according to Ptolemy, are 31; according to Tycho, 32; according to Hevelius, 40; according to Bayer, 33; and according to Mr. Flamsteed, &c. The longitudes, latitudes, magnitudes, &c. whereof, are as follow.

DRACO, DRAGON, in *Natural History*, a fabulous animal, which has been represented under the form of a serpent with wings and feet. The ancients have given various descriptions of this animal, with respect to its size, shape, and colour, and have attributed many ill qualities to it, without foundation. Their accounts of it are very various and contradictory. They were probably led to the idea they formed of it by some extraordinary animals of the genus of serpents, lizards, or crocodiles, &c. which were singular either on account of their figure or size. See DRAGON.

DRACO, or DRAGON, in *Astronomy*, is the symbol of Janus, and also of Bacchus Berosus. *Dracus* are likewise employed to draw the chariot of Ceres; and a *dragen* keeps the garden of the Hesperides.

DRACO *Morini*, in *Ichthyology*, the name of a fish of the *TRACHINUS*, kind, known in England by the name of the weever. It is a very long-bodied fish, somewhat flat, with a crooked belly, and straight back; the mouth is large, and the lower-jaw is longer than the upper. It has two fins on the back; the foremost of these is very short, and the other very long. The foremost of these fins has several prickly points, lined with black, and these are said to inflict a sort of poisonous wound; the second consists of several soft rays; it commences just at the end of the first, and continues almost to the tail; the pectoral fins are broad and angular, and the ventral

ventral fins small. Its tail is but slightly forked, and is bluish in colour. The vent is placed very forward, very near the throat. The sides are marked lengthways with two or three dirty yellow lines, and transversely by a number of small ones: the belly of this fish is silvery; its flesh is delicate, and it grows in some less to twelve, or even eighteen inches in length. The fishermen are much afraid of its pricking them, and always, as soon as they have caught it, cut off the back fin. This fish buries itself in the sands; and if trod on, strikes with great force. The wounds it gives are attended with pain and inflammation; sea-bad, or stale urine warmed, and rubbed on the place affected, is applied as a remedy; and when the wound has been dangerous, sweet oil has been applied, and opium and Venice treacle taken internally with success.

DRACO VELANS, in *Natural History*, a name given by some people to one of the flying LIZARDS. But among *Metamorphoses*, it is used for a fat, heterogeneous, earthy meteor, appearing long and sinuous, something in the shape of a flying dragon.

This shape is supposed to arise from the hind part of the matter of this meteor being fired with greater impetuosity than what comes first out of the cloud, and it is supposed, that the broken parts of the cloud, and the sulphurous matter which adhere to them, form the apparent wings of this imaginary dragon.

This sort of exhalation is principally seen on the borders of rivers, and in marshy places, and seldom rises very high from the ground, but plays and dances about the surface in an agreeable manner; and if people go up to it, it will stick to their hands or cloaths without burning, or doing them any injury. They are more common in the summer months than in the winter, and are more frequently seen in thick weather than in clear.

DRACOCAPHALUM, in *Botany*. See *DRAGON'S HEAD*. **DRACONARIUS**, in *Antiquity*, *Dragon-leader*. Several nations, as the Persians, Parthians, Scythians, &c. bore dragons on their standards; whence the standards themselves were called *draceni*, *dragons*. The Romans borrowed the same custom from the Parthians, or, as Cæsar has it, from the Daces; or, as Codin, from the Affyrians.

The Roman *draceni* were figures of dragons painted in red on their flags; as appears from Ammianus Marcellinus; but among the Persians, and Parthians, they were like the Roman eagles, figures in full relief; so that the Romans were frequently deceived, and took them for real dragons.

The soldier, who bore the dragon or standard, was called by the Romans *dracinarium*; and by the Greeks *δρακονοφεύς*, and *δρακονοτομος*; for the emperors carried the custom with them to Constantinople.

Pet. Discours. Chron. Casin. lib. iv. cap. 39. observes, that the bishops, cardinals, flauriphors, aquiliferi, leoniferi, and draconarii, all marched before king Henry when he entered Rome.

DRACONIS, caput. See **CAPUT** and **DRAGON**.

DRACONIS, cauda. See **CAUDA**.

DRACONIS, fanguis. See **SANGUIS**, and **DRAGON**.

DRACONIS, ventris. See **VENTER**.

DRACONTEAS, a name given by Neophytus, and some others of the later Greek writers, to two plants distinguished by the epithets of the great and the little kinds. The great *dracontea* is the plant we call dragon, and the small *dracontea* is the arum. Neophytus says, that the roots of some species of the small *dracontea* were eatable, which we also know to be true at this time; for though with us the juice of this plant is fiery and corrosive, yet we know that there are excellent arums in other parts of the world. The Greek writers, from the earliest times we have accounts of, were not ignorant of this; and Theophrastus in particular has described an excellent-rooted arum under the name of arum edosimum.

DRACONTHIMA, a name used by some of the old writers in medicine for what we call *fanguis draconis*, or dragon's blood, a red vegetable resin.

DRACONTIA, or **DRACONTIA LITHA**, in *Natural History*, a name given by authors to a roundish or oval pellucid stone, which seems no other than a crystal cut into that form, and polished by the savage inhabitants of several nations before the Roman conquests, and intended to be worn as ornaments. Authors tell a number of idle and fabulous stories about this stone, imagining it to be naturally of this figure and polish, and to be found in the head of a dragon. They are not indeed all agreed about the species of the stone; Plineus describing an althorne under this name, and others some other coloured stone; but the generality of writers, especially the old ones, make it colourless and pellucid.

DRACONIC MOUNTAIN, the place of time wherein the moon going from her ascending node, called *caput draconis*, returns to the same.

DRACONTIUM. The Greeks, from whom the botanical writers have taken this name, never used it singly as the denomination of a plant, but only as an adjective expressing some peculiarity in which that plant differed from some others of the same species. Thus the plant which we now call simply *dracontium*, was called by the Greeks *arum dracontium*, that is, the arum with stalks spotted like dragons or snakeskins; and the plant we call *dracunculus*, or tarracon, had the same epithet from its fiery heat. See **DRAGON**.

DRACUNCULI, in *Medicine*, a name used by authors for a sort of long and slender worms, which breed in the muscular flesh of the arms, legs, &c. and from their being more frequent in some parts of Guinea than elsewhere, are called by many Guinea-worms. They have been long known in the world; and Plutarch quotes Agatharides for an account of these animals, which, he says, the people about the Red-sea were at a certain time very much afflicted with. It is more particularly a disease in children, whereas they feel a vehement itching; supposed to arise from these worms, called *dracunculi*, generated of a vitid humour under the skin, about the back, shoulders, and arms.

Children seized with the *dracunculi* become hostile, and scarce receive any nourishment at all, though they eat plentifully. The disease, however, is not so peculiar to children, but that grown persons have been sometimes affected with it. The emperor Henry V. is said to have died of it, having had it from his birth.

The women in Poland cure their children of the *dracunculi*, after the following manner: the child is washed, and bathed in warm water, wherein a quantity of crummed-bread, and a handful of ashes have been cald. The water being poured off, and the bread gathered into a mass, when they come to break it again the next day, they find in it an infinite quantity of fine hairs, which some call *dogs hairs*, and others, *worms*; and it is these hairs, or worms, which are supposed to be the cause of the disease.

After thus bathing the children, they rub their shoulders and arms with flour steeped in vinegar, or honey; upon which immediately there rises on the skin a great number of tubercles, like poppy-seed; supposed to be the heads of worms. These they scrape off as fast as they appear; otherwise they withdraw beneath the skin again. The operation is repeated till such time as no more tubercles arise.

The *dracunculi* is a disease little known in England. The editors of the *Lessicæ Actæ*, speaking of it, in the tome for the month of October, 1682, call the bodies, which put forth at the pores after bathing, thick hairs, *capitata pilorum crassiorum instar dactylæ & spissæ*, and not fine slender hairs, as *Dragon* calls them. They add, that these little capricles are hence called *dracunculi*; and by reason of their devouring the food, which should nourish the children, *comedores*. Valsenius, in a curious dissertation on the subject, calls them *capillariæ vermes*; *serpentes de vermibus capillaribus infantum*.

As to the nature and figure of these little bodies, the same editors observe, that the microscope have put it past doubt, that they are real living animals, of an alcock-like, having two long horns, two large round eyes, and a long tail, terminated with a tuft of hair; but that it is difficult to draw them out whole, by scraping the child's body, because, being very soft, the least rubbing bruises them, and breaks them.

They are no where so frequent as on the Gold-coast in Guinea about Annamaboe and Cormantyn. The worm is white, round, long, and uniform, very much resembling a piece of white round tape or bobbin. It is lodged between the interstices of the membranes and muscles, where it insinuates itself to a prodigious length, sometimes exceeding five ells. It occasions no great pain in the beginning; but when it is about to shew its head, a swelling and inflammation appear on the part, which is usually the ankle, or some part of the leg or thigh.

The countries where this creature is thus produced are very hot, and subject to great droughts, and the inhabitants make use of stagnating and corrupted water, in which it is probable the ova of these animals lie: the white people and negroes, who drink this water, are equally subject to these worms.

The surgeons seldom attempt to extract this worm by incision; but when the tumor appears, they endeavour to bring it to a suppuration as soon as they can; and when they have broke the swelling, and the head of the worm appears, they fasten it to a stick, and continue gradually winding it round at the rate of an inch or two in a day, till they by this means, have wound it all out. If it be wound too hastily, it is apt to break in the operation; and if it does the end is not easily recovered again; and if not, there are abscesses formed, not only at the place where it breaks, but all along the whole winding of the muscles

muscles where the dead worm remains; so that often from one worm thus broken, there are produced a number of oblongate ulcers in different parts. When the worm has not been broken, the ulcer out of which it was extracted heals easily, and there is no further trouble about it. Town's *Dissert.* of the West Indies, p. 551.

The daily use of aloes, or of any other anthelmintic medicine, is proper, during the extraction of the worm, in order to facilitate its discharge. See *CHARTA*.

DRACUNCULUS, in *Ichthyology*, the name of a sea-fish, called by Bellonius and Gelfert, a kind of the exocoetus. It is a small fish, about a hand's breadth long, and sometimes a little larger. It is of a long and rounded body, and of a dead greenish or olive colour on the back, and white on the belly, and is marked on the sides with a great number of bluish, white, and very light small spots. On the upper part of the head, which is large, and flat at the top, below the eyes, it has a purplish triangular spot; the eyes are large, and so placed in the upper part of the head, as to look upwards, whence it has been ranked among the *URANOSCOPUS*; the mouth wide, and furnished with small teeth; and the upper-jaw is longer than the under. The apertures of the gills are closed, on the end of the bones that cover them is a very singular trifurcated spine. This fish has two pair of fins on the belly, and two fins on the back, situated in a kind of furrow, the tail is long and rounded, and consists of ten rays. It is common in the Mediterranean, and other seas, and is brought to market among other small fish at Rome, and in other places. In the Linnaean system it is a species of the *CALIONYMUS*. See *Tab. II. of Fish*, N° 10.

DRACUNCULUS, in *Batany*. See *DRACONIS*.

DRAFT, a name given in some places to the wain given to hogs; and the grains given to cows.

DRAQ, in *Building*. A door is said to drag, when in opening or shutting it hangs, or grates upon the floor.

DRAQ-ROPE. See *ROPE*.

DRAQ, in *Sea-Language*, is a machine, consisting of a sharp, figure, iron ring, encircled with a net, and commonly used to take the wheel off from the platform or bottom of the decks.

DRAGING HIS ANCHOR. See *ANCHOR*.

DRAUMA, in *Pharmacy*, a name used by the ancients for a handful of any herb or other medicine.

DRAUMIS, in *Pharmacy*, a word used by the ancients to signify a pugil, or as much of any thing as can be taken up at a pinch, between the thumb and two fingers.

DRAOMAN, or **DRAOMAN**, a term of general use through the East, for an interpreter, whose office is to facilitate commerce between the originals and occidentals. These are kept by the ambassadors of Christian nations residing at the Porte, for this purpose.

The word is formed from the Arabic *targuman*, or *targiman*, of the verb *targam*, he has interpreted. From *dragoman*, the Italians formed *dragomani*, and with a nearer relation to its Arabic etymology, *tarcimanes*; whence the French, and our *dragman*, as well as *dragoman*, and *dragman*.

DRAON, in *Astronomy*. See *DRACO*.

DRAGON'S head, and tail, *caput & cauda draconis*, are the nodes of the planets; or the two points, wherein the ecliptic is intersected by the orbits of the planets, and particularly that of the moon; making with it angles of five degrees and eighteen minutes.

One of these points looks northward; the moon beginning then to have northward latitude, and the other southward; where she commences south.

This her deviation from the ecliptic forms (according to the fancy of some) to make a figure like to that of a dragon, whose belly is where she has the greatest latitude; the intersection representing the head and tail, from which resemble the denomination arises.

But now, that these points abide not always in one place, but have a motion of their own in the zodiac, and retrograde-wire, 3 minutes 11 seconds per day; completing their circle in 18 years 225 days; so that the moon can be but twice in the ecliptic, during her monthly period; but at all other times she will have a latitude, or declination from the ecliptic.

It is about these points of intersection that all eclipses happen.

They are usually denoted by these characters, $\cap$ *dragon's head*, and $\cap$ *dragon's tail*.

DRAGON-LEAVES, in *Architecture*, are two strong braces or struts, which stand under a breast-summit, and meet in an angle on the shoulder of the king-piece.

DRAGON'S blood, *sanguis draconis*, in *Medicine*, a refinous substance brought from the East, in oval drops, wrapped up in flax-leaves, of considerable use, as an agglutinant and desiccative, against fluxes, both alvine and uterine, and ulcerations internal and external, &c.

It derives its name *dragon's blood* from the redness of its colour, and gives its name *dragon* to the tree that yields

it. Some botanists talk of the figure of a dragon, barely represented under the mind of the fruit of that tree. But this is a mere fiction.

The genuine *dragon's blood* is the juice, or resin, of a large tree, called *drag arbor*, the *dragon-tree*, resembling the palm, growing in Africa, and America, as well as in China. The resin is of a dark red, and in substance of no discernible smell or taste, and easily dissolves when brought towards the fire; if cast into the fire, it flames; but it dissolves with much difficulty in any watery liquor. It is soluble by the assistance of heat in rectified spirit, and in expressed oil, to which it communicates a deep red colour.

It is a good astringent; and is used in hemorrhages and dysenteries; as also to fatten the teeth, and strengthen the gums. A solution of *dragon's blood* in spirit of wine is used for staining marble, to which it gives a red tinge, which penetrates more or less deeply, according to the heat of the marble during application. But for fine designs, the marble should be cold, because it spreads while it sinks. Mr. Du Fay says, that by adding pitch to this solution, the colour may be rendered deeper.

There is also a counterfeit *dragon's blood*, made of the gum of the cherry, or almond-tree, dissolved, and boiled in a tincture of Brazil wood; but this is of no use, except for external discharges of horres. These adulterated resins are distinguished from the true by their dissolving in water, and cracking in the fire without burning.

DRAGON-KNIGHTS, an order of knighthood instituted by the emperor Sigismund, about the year 1418, after the council of Constance, in memory of the condemnation of John Huss and Jerome of Prague. This order, which once flourished in Germany and Italy, is now extinct.

DRAGON-FLY, *Libella*, or *Libellula*, in *Natural History*, the name of a very large genus of four-winged flies, called by us *adder-flies*, and *dragon-flies*. They belong to the order of *anuroptera* in the Linnaean system; they are characterized by having jaws, by antennae shorter than the thorax, by extended wings, and by the male's tail being terminated by a hooked kind of forceps. See *FLY-Tab. of Ichthyol.* fig. 1.

These flies have all two very large and articulated eyes, covering the whole surface of the head, which are a beautiful object for the microscope. They fly very swiftly, and prey upon the wing, being of great use to mankind, in clearing the air of innumerable little flies.

They are produced of several species of sex-legged worms living in the waters, and figured by Mouslin, and other authors, under the name of *gallies* and *larvæ aquaticæ*.

Mr. Ray describes twenty-three species of these flies. Most of these species are found in August and September, in our fields and gardens, especially near places where there are waters, as they have their origin from worms living in that element. The great ones usually live all their time about waters, but the smaller are common among hedges, and the smallest of all are most frequent in gardens. The smaller kinds often settle upon bushes or upon the ground; but the large ones are almost always upon the wings, so that it is very difficult to take them. Ray's *Hist. Insect.* p. 50.

The manner of this insect's coupling with the female is a thing that has attracted the observation and admiration of multitudes, as they are frequently seen, in the hotter months, in that state, flying together about the edges of waters.

Mr. Homburg, of the Academy of Paris, has taken great pains to inform the world of the whole secret of this strange coitus, and of several other remarkable particulars in regard to the creature. The part to which the wings are fixed is called the breast in animals of this kind; but in this creature the lungs are not situated there, but in the middle of the belly, which is seen continually rising and falling at inspiration and expiration. The last joint of the body of the male is a ring containing the anus, and this is furnished with two pair of hooks; the one pair outward and larger, the other inward and smaller; these the creature is able to open and shut at pleasure at their claws. The extremity of the belly of the female seems to consist of two tubes, or pipes, one placed upon the other; the upper one is the anus, at which it voids its excrement; the under one is the female part of generation, and the entrance to the womb of the animal. When the male of this species finds the female sitting upon a leaf, or stick, he seizes her as she flies, taking fast hold of her with the hooks at the anus by the neck, or that part which joins the head to the breast, and immediately flies away with her, holding her fixed by the neck to the end of his tail.

The male does not carry his bride far before he settles himself upon some plant, and raises his tail so, that the female may be brought to sit easily under him upon the same plant. As soon as the female is thus seated, the

turns up her tail, and brings it between the legs of the male, then places it to a certain part of the breast of the male, in which are the organs of generation in that sex. All this while the male keeps his hold of her neck with his forepaw, or hooks. They usually remain in this posture about three minutes; and after that the male gently raising up his breast, they become separated, and leaving the hold he had on her neck, at the same time, he flies away as he pleases. The female usually remains on the place for half a quarter of an hour, and then she flies away also. Mr. Homburg having observed the coupling of these animals thus far, was determined to examine the organs used in it by dissection. To this purpose he caught several of them, and on the whole collected several curious observations, which may be seen in Mem. Acad. Par. 1699.

DRAGON, gum. See **TRAGACANTH.**

DRAGON'S HEAD, *Dracephalum*, in Botany, a genus of the *diapnomia cynosformis* class. Its characters are these: the flower has one tingent petal, with large, oblong, inflated chaps; the upper lip is obtuse and arched, the under trilobed. It has four stamens, two shorter than the others; and a four-parted germen, which becomes four oval, oblong seeds, enclosed in the empalement. Linnaeus enumerates thirteen, and Miller eight species, one of which is the balm of Gilead; they all require little culture, except keeping clear from weeds.

DRAGON-FISH, in Natural History, a name given by people, curious in shells, to a species of concentered patella or limpet. This has a top very much bent, and is of an ash-colour on the outside, but of an elegant and bright blue-colour within. This has been found sticking on the back of a tortoise, as the common limpets do on the sides of rocks; and some have been found affixed to large shells of the pinnas marinas, brought from the East Indies at different times.

DRAGON, Sea. See **DRACO MARINUS.**

DRAGON, ship. See **SNAR DRAGON.**

DRAGONS, *Draconium*, in Botany, a genus of the *gynandria polyandra* class. Its characters are these: it hath a close cylindrical spadix, and a boat-shaped sheath; the flowers have no empalement, but have five oval concave petals. They have an oval germen, which afterward becomes a roundish berry, including several seeds. There are five species.

All the species are propagated by parting their knobby roots, which when they have stood undisturbed for three years, will afford a great number of offsets. These are to be taken off and planted in autumn, soon after the green leaves decay; for if they are removed after they have taken fresh root, and begun to shoot, they seldom produce flowers the succeeding summer; or if they do, they are very weak; they will thrive in almost any soil and situation.

Dragons are accounted a good alexipharmic, and useful in malignant contagious distempers, and pestilential fevers; and, as the vulgar phrase is, to drive any thing from the heart. Wherefore it is given in medicines to drive out the small-pox and measles, and to cause sweat. Miller's Bot. Off.

They have, much the same medical virtues with the **ARM, or WAKE-RHIN.**

DRAGON-TREE. See **PALM-TREE.**

DRAGON, wild, and wurt. See **SOUTHERNWOOD,** and **MUGWORT.**

DRAGONET, in Ichthyology, a name given by Pennant to the **DRACONULUS.**

DRAGONNEE, in Heraldry. A lion *dragonnee*, is where the upper half resembles a lion; the other half going off like the hind part of a dragon.

The like may be said of any other beast as well as the lion.

DRAGON, in Ornithology, the name of a small kind of *CARRIER-PIGEON*, called *columba telularia minor* by Moore. It is a bassant-breed between the two species of pigeons called the *harpizan* and the *tumbler*. They are very good breeders, and as they are lighter than the *harpizan*, they are supposed more expeditious in flight for a few miles, but the *harpizan* outdoes them at greater lengths. One of these pigeons flew from St. Edmundsbury to London, being a distance of seventy-two miles, in two hours and a half.

DRAGONS, in War, an order of soldiery, who march on horseback, and fight on foot, though sometimes, too, on horseback.

Menage derives the word *dragon* from the Latin *drac-narius*, which in Vegetius is used to signify soldier. But it is more probably derived from the German *tragen*, or *draghen*, which signifies *to carry*; as being infantry carried on horseback.

They are divided into brigades, and each regiment into troops. They encamp generally on the wings of an army, and sometimes they cover the general's quarters. The first regiment of *dragons* raised in England, was in Vol. II. N° 102.

1681, and called the regiment of *dragons* of North Britain. In battle, or attacks, they generally fight sword in hand after the first fire. In the French army they are said to ride without boots.

Their arms are, a sword, firelock, and bayonet. In the French service, when the *dragons* march on foot, their officers bear the pike, and the sergeants the halbert; neither of which are used in the English service.

DRAGS, in the Sea-Language, is used for whatever hangs over the ship in the sea, as shirts, coats, or the like; and boats when towed, or whatever else drift, after this manner, may hinder the ship's way when the sails.

DRAIN, or DRAIN, in the Military Art, a trench made to draw the water out of a moat, which is afterward filled with hurdles and earth, or with fascines, or bundles of rushes and planks, to facilitate the passage over the mud. See **TECHNIQUES.**

DRAINS, a name given in the fen-counties to certain large cuts or ditches, of twenty, thirty, nay sometimes forty feet wide, carried through the marshy ground to some river, or other place capable of discharging the water they carry out of the fen-lands. Most of these *drains* are made in our fen-counties by a body of men called the *undertakers*, whose reward is one third of the ground they *drain*. They also erect sluices at a great expense, often not less than two thousand pounds each. Yet these, with all the care they employ in erecting them, are subject to be blown up by the vast weight of water that lies upon them when the lands are overflowed. Some of these sluices have two or more pair of doors, of six, eight, or ten feet high, which shut when the water in the river is higher than in the *drains*, by the weight and force of it; and so *à ventura*, throw out a body of eight feet square of water for about six or seven hours during the ebb. The real use of these *drains* is very evident from the present state of the land where they are cut, and that of it before. In Camden's time all this was bog, and now it is all firm land. The country about Crowland was in that author's time so lost, that it was not passable by carriage; and thus grew a wilderness upon it, that all the carts that entered this town were caked on the wheels with siver; but this is now so firm ground, that carriages of any kind pass over it. The duck-ponds used to be called the *fen coen*-fields, and they now are such in reality, their bottoms being dry, and producing oats, and rape-seed, or sole-seed, with great increase. Phil. Trans. N° 273.

Drains are also more generally used to carry off the superfluous moisture from wet and marshy lands. For this purpose a deep *drain* must be cut in the lowest part; so as to reach the bed, whether of gravel or sand, through which the water flows; and smaller *drains* should be made from this ditch to those places which appear to be the heads of springs; and these should be left open for some time, till the quantity of moisture abates; they should then be filled up about Michaelmas with stones, and over these heath, broom, or straw, or with faggots made of the branches of trees. A foot depth of mould over the *drain* will be sufficient in pasture-ground; and at least a foot and a half in ploughed lands. But if the quantity of water to be discharged is considerable, the main *drain* should either be left open, or made very deep and wide, and filled with stones. See **BOG.**

It may be necessary, in many cases, and has proved very useful, to flag the bottom, and to line the sides of the *drains* with tiles, brick, or stone, to keep the earth from falling in, and to preserve a free passage for the water. The clay which is dug out of these *drains* may be converted, either by burning, or laying up in heaps with quicklime, into an excellent manure, either for corn or grass land, where it is most wanted.

When the ground in which the springs are, lies on a gentle declivity, Mr. Tull advises to plough it in an horizontal direction, by which means each furrow carries off the water, which would otherwise sink into the next ridge. See **FEN.**

DRAINING Plough. See **PLOUGH.**

DRAM. See **DRACHM.**

DRAMA. See **CORDIALS.**

DRAMA, in Poetry, a piece, or poem, composed for the stage.

The word is Greek, *drama*, which literally signifies *acting*; because in *dramas*, or dramatic poems, they act, or represent actions, as if they really passed.

A *drama*, or as we popularly call it, a *play*, is a composition either in prose or verse, consisting, not in the simple recitation, but in the actual representation of an action.

Our *dramas* are, **TRAGEDIES, COMEDIES, OPERAS,** and **FARCES.**

Some critics take the book of Canticles for a *drama*, or *dramatic poem*; others maintain the same of the book of Job. Some scrupulous authors would restrain *drama* to

serious pieces, as tragedies; but with respect to the etymology, a comedy is as much a *drama*, as a tragedy.

The primary parts of the *drama*, as divided by the ancients, are the *prologus*, *epilogus*, *cataglyphi*, and *cataglyphi*.

The secondary parts are, the *acti* and *scenae*. The necessary parts are, the *argumentum*, *summarum*, the *prologus*, *chorus*, *minimus*, *junior*, and *actus*. Lastly the *epilogus*, which pointed out the use of the piece, or conveyed some other notice to the audience in the poet's name.

DRAMATIC, in *Poetry*, is an epithet given to pieces written for the stage.

For the laws of dramatic poetry, see **UNITY**, **ACTION**, **CHARACTER**, **FABLE**, &c.

Style DRAMATIC. See **STYLE**.

DRANK, a name given by our farmers to the great wild

oats. These are often very troublesome to the ploughed lands, especially after wet seasons and much frost. Many to destroy this weed sow the land with black oats, which being ripe much sooner than the seeds of this plant, are cut down before it can grow itself for another year; especially if they are cut a little the earlier, which will do them no harm, if they be suffered to lie a while upon the ground afterwards, for the grain to swell before they are carried in. But, in general, when ploughed lands begin to run to these weeds and thistles, it is a token to the farmer that it is time to follow them, or else to sow them with hay-seeds, and make pastures of them. The sowing being upon a land subject to these weeds is also a good method, because the farmer may send in his sheep when they are about three inches high, which will eat up the *drank*, and all the other weeds, and will not hurt the beans. The general method is to put twenty sheep to an acre; but they must be put in only in dry weather, and not left too long.

DRAPERY, in *Painting and Sculpture*, the representation of the garments, or clothing of human figures.

The word is French, *draperie*, formed from *drap*, cloth. In the general sense, *drapery* includes not only the garments, but also the tapestry, linens, and most other things that are not carnations, nor landscapes.

The art of *drapery* consists chiefly in three points, viz. the ordering of the folds, or plait; the different quality of the stuffs; and the variety of their colours.

As to the folds, they should be so managed, that you may easily perceive what it is that they cover, and distinguish it from any thing else. For instance, that you see it is an arm that is under the *drapery*, and not a leg, &c.

The folds, again, must be large, or breaking and dividing the light the best. There should likewise be a contrast between them, otherwise the *drapery* will appear stiff.

The quality of the stuffs should likewise be well considered. Some make their folds abrupt, and harsh; and others more soft and easy. The surface of some, again, has a lustre; others are dull; some are fine, and transparent; others strong, and solid.

The variety of colours, when well managed, makes the great beauty of a painting; all being not equally amicable, and friendly, with respect to each other; and some are never to be placed near certain others.

M. de Piles gives abundance of good observations relating to *drapery*. "Their first effect," he observes, "and that which the painter ought to have principally in view, is, that they express the thing they are supposed to cover; and that they must never be made to adhere, and stick to the parts of the body; a great lightness, and motion of the *drapery*, are only proper for figures in great agitation, or exposed to the wind. The nodities of the figures should always be designed, before the painter proceed to the *drapery*." Titian, Paul Veronese, and Vandyke, excelled in *drapery*.

DRANTIC, from *Draco*, a strong and powerful medicine; more particularly, a purgative that works with speed and vigour; as jalap, scammony, and the other stronger cathartics.

DRAUGHT, in *Medicine*. See **POTION**.

DRAUGHT, in *Trade*, is an allowance made in the weight of commodities; the same as **CLOUGH**.

DRAUGHT is also used sometimes for a bill of exchange, and commonly for an order for the payment of any sum of money due, &c. Then the person who gives the order is said to *draw* upon the other.

DRAUGHT, in *Painting*, &c. See **DESIGN**.

DRAUGHT, or, as it is pronounced, **DRAFT**, in *Architecture*, the figure of an intended building described on paper; wherein are laid down, by scale and compass, the several divisions and partitions of the apartments, rooms, doors, passages, conveniences, &c. in their due proportion.

It is usual, and even exceedingly convenient, before a building is begun to be raised, to have *draughts* of the ichnography, or ground-plan of each floor, or story; as also of the form and fashion of each front, with the

windows, doors, ornaments, &c. in an orthography, or upright.

Sometimes the several fronts, &c. are taken, and represented in the same *draught*, to shew the effect of the whole building: this is called a *panoramy*, or *perspective*. See **SCENOGRAPHY**.

DRAUGHT, reduction of a. See **REDUCTION**, and **PEN-TAGRAM**.

DRAUGHT, compass, those provided with several moveable points, to draw fine *draughts* in architecture, &c. See **COMPASS**.

DRAUGHT, boats, are large boats of iron fixed on the cheeks of a cannon carriage, two on each side, one near the trunnion-hole, and the other at the train, and are called the fore and hind *draught-boats*. Large galleys have *draught-boats* near the middle trunnion, to which are fixed the chains, which serve to ease the shafts of the limbers on a march. The fore and hind-boats are used for drawing a gun backwards or forwards by men with strong ropes, called *draughts*, or *drag-rope*, fixed to these hooks.

DRAUGHT, horse. See **HORSE**.

DRAW. A ship is said to *draw* so much water, according to the number of feet the sink into it.

Thus, if fifteen feet from the bottom of her be under water, or if the sink into the water fifteen feet perpendicularly, she is said to *draw* fifteen feet water; and according as she *draws* more, or less, she is said to be of more, or less *draught*; and that this may be more readily known, the feet are marked on the stem and stern-post regularly from the keel upwards. *Drawing* denotes also the state of the sail, when it is inflated with the wind, so as to advance the vessel in her course.

DRAW, in the *First Law*. See **DRAW**.

DRAW, in *Commerce*, a rebate, or discount, upon the price of commodities, purchased on certain conditions. See **REBATE**, and **DISCOUNT**.

Draw-back is more particularly used to denote certain duties, either of the customs or of the excise, that are allowed upon the exportation of some of our own manufactures, or upon certain foreign commodities that have paid a duty at importation.

The oaths of the merchants importing or exporting are required, to obtain the *draw-back* of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties; and these may be made by the agent or husband of any corporation or company, or by the known servant of any merchant, usually employed in making his entries, and paying his customs.

2 and 3 Ann. cap. 2. With respect to foreign goods entered outwardly, if left in quantity or value be handsomely shipped out than is expressed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no *draw-back* is to be allowed for the same.

Foreign goods exported by certificate, in order to obtain the *draw-back*, not shipped or exported, or re-landed in Great-Britain, unless in case of distress, to save them from perishing, which must be immediately signified to the officers of the customs, or to the benefit of the *draw-back*, and are forfeited, or their value, with the vessels, horses, carriages, &c. employed in the re-landing of them; and the persons concerned in re-landing them, or by whose privacy they are re-landed, or into whose hands they shall knowingly come, are to forfeit double the amount of the *draw-back*.

13 and 14 Car II. cap. 11. 8 Ann. cap. 13. This is to be paid for within five years after the offence. And the seizure of the horses, &c. may be adjusted by two or more justices of the peace. 6 Geo. I. cap. 21. 8 Geo. I. cap. 16. and 11 Geo. I. cap. 29. Officers of the customs convicting, or assisting in any fraud relative to certificate goods, beside other penalties, are to forfeit their office, and to suffer six months imprisonment, without bail or main-prize; as are also masters or persons belonging to the ships employed in this business. 8 Ann. cap. 13. Bonds given for the exportation of certificate goods to Ireland must not be delivered up, nor *draw-back* allowed for any goods, till a certificate under the hands and seals of the comptroller, or collector, &c. of the customs of some port in Ireland be produced, certifying the landing, which certificate must be produced in six months from the date of the bond. 8 Ann. cap. 13. 5 Geo. I. cap. 11. 9 Geo. I. cap. 8. 3 Geo. II. cap. 28. See **CUSTOMS**, **DEBENTURES**, **DUTIES**, &c.

DRAW, bridge, a bridge made after the manner of a floor, to be drawn up, or let down, as occasion serves, before the gate of a town or castle. See **RAIPE**.

DRAW, gear, in *Husbandry*, any kind of harness for drawing a wagon or other carriage.

DRAW, net, a kind of net for taking the larger sort of wild fowl, which ought to be made of the best pack-thread, with wide meshes: they should be about two fathoms deep, and six long, verged on each side with a very strong cord, and stretched at each end on long poles.

It should be spread smooth and flat upon the ground, and strewn over with fedge, grass, or the like, to hide it from the fowl; and the sportsman is to place himself in some shelter of grass, fern, or some such thing.

DRAWER of a bill of exchange, &c. the person who draws the bill upon his correspondent. See BILL, and EXCHANGE.

DRAWING a cost, among Bowlers. See BOWLING.

DRAWING, medicine, or DRAWERS. See EPISPASTIC, and RUPERS.

DRAWING, teeth. See TOOTH-drawing.

DRAWING of gold, or silver, is the passing of it through a number of holes in an iron, each less than another, to bring it into a wire. See WIRE-drawing, and DUCTILITY.

DRAWING of a bill of exchange, is the writing, signing, and giving it to the person, who has already paid the value, or content thereof, to receive it in another place.

A person should never draw a bill of exchange, unless he be well assured it will be accepted, and paid. See BILL of Exchange.

DRAWING, in Painting, &c. See DESIGNING, and COUNTER-DRAWING.

DRAWING, among Hunters, is, when they beat the bushes after a fox.

DRAWING amiss, is, when the hounds, or beagles, hit the scent of their chase the contrary way, so as to pursue it up the wind, when they should have done it down the wind.

DRAWING on the flat is, when the hounds touch the scent, and draw on, all they rout, or put up the chase.

DRAWING, fire. See FIRE-drawing.

DRAY, a name given by sportsmen to squirrel nests, built on the tops of trees. See SQUIRREL.

DRAY is also a cart used by brewers to carry beer on; likewise a sledge without wheels.

DRAY, plough. See PLOUGH.

DREAMS. According to Wolfius every dream takes its rise from some sensation, and is continued by the succession of phantasms in the mind. His reasons are, that when we dream we imagine something, or the mind produces phantasms; but no phantasm can arise in the mind, without a previous sensation; hence neither can a dream arise without some previous sensation. He observes farther, that though it be certain *a priori*, from the nature of the imagination, that dreams must begin by some sensation, yet that it is not easy to confirm this by experience; it being often difficult to distinguish those slight sensations, which give rise to dreams, from phantasms, or objects of imagination. Yet this is not impossible in some cases, as when the weak sensation sufficient to give rise to a dream gradually becomes stronger, so as to put an end to it, as it often happens in uneasy and painful sensations. Wolf. Psychol. Empir. § 123.

The series of phantasms, or objects of imagination, which constitute a dream, seem to be sufficiently accounted for, from the law of imagination, or of association; though it may be extremely difficult to assign the cause of every minute difference, not only in different subjects, but in the same, at different times, and in different circumstances. We have an essay on this subject by M. Forney, in the *Mém. de l'Acad. de Berlin*. tom. ii. p. 216. He expressly adopts Wolfius's proposition above mentioned, that every dream begins with a sensation, and is continued by a series of acts of imagination, or of phantasms; and that the cause of this series is to be found in the law of the imagination. *Si naturale somnium est, initium capere debet per legem sensationis, et continuari per legem imaginativitatis.* Hence he concludes those dreams to be supernatural, which either do not begin by sensation, or are not continued by the law of the imagination.

This opinion is as ancient as Aristotle, who expressly asserted, that a dream is only the *parænesis*, or appearance of things, arising from the previous motions excited in the brain, and remaining after the objects are removed. Hobbes has adopted this hypothesis: he ascribes different dreams to different dispositions of the body, and whimsically enough observes, that lying cold breedeth dreams of fear, and raiseth the thought and image of some fearful object. Thus he accounts for that which was in reality the waking vision of Brutus, which addressed him the night before the battle of Philippi. "I am, Brutus, 'thine evil genius; but thou shalt see me again near Philippi." And Mr. Locke, though he does not expressly declare how dreams are excited during sleep, seems to ascribe the perfection of rational thinking to the body; and traces their origin to previous sensations, when he says, "The dreams of sleeping men are all made up of 'the waking man's ideas, though for the most part 'scattered and absurdity, of many of our dreams, as well as the supposed fact that some sleep without dreaming,

at objections to the notion that men think always: to which it has been replied, that dreams may be entirely, imperfectly, or not at all remembered, according to the various degrees in which the nerves are impressed by the motion given to the animal spirits in sleep. Arist. de Insomni. c. 3. Hobb. Lev. cap. 2. & cap. 45. Locke. Ess. book ii. ch. i. § 10, &c. Watt's Ess. § 2. p. 120, &c. Dr. Hartley explains all the phenomena of the imagination by his theory of vibrations and associations. Dreams, he says, are nothing but the imaginations or reveries of sleeping men, and they are deducible from three causes, viz. the impressions and ideas lastly received, and particularly those of the preceding day, the state of the body, and particularly of the stomach and brain, and association. Obs. on Man, vol. i. § 5. p. 283, &c.

Democritus and Lucrotius account for dreams, by supposing that species and similitude of corporeal things, constantly emitted from them, and floating up and down in the air, come and assault the soul in sleep. Lucret. De Rer. Nat. lib. iv.

Those who have maintained the essential difference between soul and body have solved the common phenomena of dreams by the union of these two substances, and the necessary connection arising between ideas in the mind, and certain motions in the body, or in those parts more immediately united to the soul; whilst others, who have denied the existence of matter, account for them in the same manner as for our other ideas, which may not be improperly called waking dreams.

A learned author has not long since asserted, that our dreams are prompted by separate immaterial beings; an opinion which was advanced long ago by the heathens, and maintained very generally, and applied to a species of DIVINATION. He contends, that the phantasms, or what is properly called the vision, is not the work of the soul itself, and that it cannot be the effect of mechanical causes; and therefore ascribes it to separate spirits, having access to our minds, and furnishing us with ideas while we sleep. See Mr. Baxter's Essay on the Phen. of Dreaming, in his Inquiry into the Nature of the human Soul, vol. ii. 3d edit. 1745.

The physicians who have accurately examined the state of their patients in every particular circumstance, have not omitted, at times, to enquire into their dreams in those hours of sleep which their ill state allows them, and partly from experience, partly from reason and analogy, have found, that there are many presages of disease to come, and many indications of such as are present, but unperceived, at least not seen in their full extent, to be had from what the senses suffer in dreams. Indeed, if dreams are different from what might be expected from the business of the day, or the turn of thought before, they may always be looked upon as signs of a more or less disordered state of the body; and the true condition of that state may often be better learned from them, than from any other means. What has been observed by physicians in regard to the prognostics from dreams, may be summed up in the following manner: to dream of fire, indicates a redundancy of yellow bile; to dream of fog or smoke, indicates a predominance of black bile; to dream of seeing a fall of rain or snow, or a great quantity of ice, shews that there is a redundancy of phlegm in the body; he who fancies himself among flames may be assured, that he harbours some putrid matter in his body; to have red things presented before you in sleep, denotes a redundancy of blood; if the patient dreams of seeing the sun, moon, and stars, hurry on with prodigious swiftness, it indicates an approaching delirium; to dream of a turbid sea, indicates disorders of the belly; and to dream of seeing the earth overflowed with water, or of being immersed in a pond or river, indicates a redundancy of watery humours in the body; to dream of seeing the earth burnt or parched up, is a sign of great heat and dryness; the appearance of monsters and frightful enemies, indicates delirium in diseases; and to dream often of being thrown down from some very high place, threatens an approaching vertigo, or some other disorder of the head, as an epilepsy, apoplexy, or the like. These and a great many others are the observations of Hippocrates on the dreams of his patients. From those, and from other farther assistance, Lomius has carried the subject to a very great length, and given many rules of judging from them. Lomii Med. Obs. But quære, how true.

DREDGE, or **DAGO**, a term used by the farmers for oats and barley mingled together.

DREDGERS, a term used in the admiralty courts for the fishers for oysters. See stat. 2 Geo. II. cap. 9.

DREGS of oil, a name given by the people who trade in oil, to that coarse and thick part of it, which subsides to the bottom of the vessels in which great quantities of it are kept. This is not fit for the common uses of the clear oil.

oil at the top, but there are several purposes to which it serves very well. Great quantities of these oils or *drays* of common oil are used by the soap-boilers, principally in making the common soft soap. The leather-dressers also use it in considerable quantities to soften the hides they are employed to prepare for the several artificers who use them. Some of these *drays* are also used in the making of flambeaux, which instead of being made of yellow wax as pretended, are usually composed of pitch, rosin, and this oil, mixed in such a proportion as to make a mass of a proper hardness and consistence. People who use presses, and other works in which there are many screws, sometimes buy this to grease their screws, instead of soap or lard. These are the uses mentioned by Savary; but beside these we have in England another manufacture, which consumes a greater quantity than all these put together. This is the making of spermaceti, some persons among us have found the art of making this out of the faeces of oil, and will give an oilman at any time as much clear oil in exchange of these *drays*, as they are in quantity. All the other uses of these *drays* leave the trader at a great loss; and as Savary observes, the more forces the oil contains, the greater is the loss to the buyer; but with us, this is rendered equal, and there is no loss in it.

All sorts of oil produce more or less faeces and *drays*, but of all others, the whale-oil is observed to produce the largest quantity, and the nut-oil the least.

DREIT DREIT, in our Old Writers, signifies a double right, that is, *ius pignoris & ius domini*. Bracton, lib. iv. cap. 27. and lib. iv. tract. 4. cap. 4. and lib. v. tract. 3. cap. 5. Coke on Litt. fol. 266.

DRENCH, among *Barriers*, a physical draught, or potion, given a horse, by way of purge.

DRENCHES, or **DRENGES**, **DRENGI**, or **THRENGI**, in our Old Writers, a term, about which the lawyers and antiquaries are little divided. See **THRENGUS**.

Drengus, says an ancient manuscript, were *tenentes in capite*: according to Spelman, they were a *genus vasallorum non feudum, cum feodalibus in domibus dominorum feudis subsisterent maneris*: such as, at the coming in of the Conquerors, being put out of their estates, were afterwards upon complaint, restored thereto; because, they, being before owners thereof, were neither in auxilio, nor consilio, against him.

DRENGAGE, **DRENGAGIUM**, vel *servitium drengagii*, in our Old Writers, the tenure by which the *drenges* held their lands: concerning which, see Term. Trin. 21 Ed. III. Ebor. and Northum. Rot. 1571. *Natumum est, ex omni curia antecessore, quod drengorum ius est, vel per drengagium tenetur, ius feudum patrimoniale ante advenum Norwicum*. Spelman. Gloss. Du-Cange, Gloss. Lat. in voc. *Drenges*.

DREPANON, *Σκωρτερον*, among the Greeks, an engine of iron crooked like a sickle, and fixed to the top of a long pole. It was used in cutting along the cords of the sail yards, in order to dislodge the ship by letting fall the sails, and was otherwise called *dorydrepanon*. Pott's Archeol. tom. ii. p. 121.

DRESSING of hemp and flax. See **HEMP** and **FLAX**.

DRESSING of h-p-r. See **HOPS**.

DRESSING of meat, the preparing of them for food, by means of culinary fire.

The design of *dressing* is, to loosen the texture of the flesh, and dispose it for dissolution, and digestion in the stomach. Flesh not being a proper food without *dressing*, is alleged as an argument, that man was not intended by nature for a carnivorous, or flesh-eating animal.

The usual operations are, *roasting, boiling, and stewing*. In *roasting*, it is observed, meat will bear a much greater and longer heat than either in *boiling*, or *stewing*; and in *boiling* greater and longer than in *stewing*. The reason is, that *roasting* being performed in the open air, as the parts begin externally to warm, they extend and dilate, and so gradually let out part of the rarefied included air, by which means the internal succussions, on which the dissolution depends, are much weakened, and abated; *boiling* being performed in water, the pressure is greater, and consequently, the succussions to lift up the weight are proportionably stronger, by which means the coction is hastened; and even in this way there are great differences: for the greater the weight of water, the sooner is the business done.

In *stewing*, though the heat be much less than what is employed in the other ways, the operation is much more quick, because performed in a close vessel, and full; by which means the succussions are more often repeated, and more strongly reverberated. Hence the force of Papin's DIGESTOR; and hence an illustration of the operation of DIGESTION.

Boiling, Dr. Cheyne observes, draws more of the rank, strong juices from meat, and leaves it less nutritive, more

diluted, lighter, and easier of digestion: *roasting*, on the other hand, leaves it fuller of the strong, nutritive juices, harder to digest, and needing more dilution. Strong, grown, and adult animal food, therefore, should be *boiled*; and the younger and tenderer *roasted*.

DRESSING of ore. See **BUNDLES**, and **ORE**.

DRESSING, in Surgery, denotes the treatment of a wound, or any disordered part. The apparatus for this purpose consists of dosils, tents, plasters, compresses, bandages, bands, ligatures, &c.

DRESSING a ship, is the act of ornamenting a ship with a variety of colours, as ensigns, flags, pendants, &c. displayed from different parts of her masts and rigging, on a day of festivity.

DRIE, or **DRE**. See **DRE**.

DRIFT, in Mining, a passage cut out under the earth between shaft and shaft, or turn and turn, or a passage or way wrought under the earth to the end of a mine of ground, or part of a mine.

DRIFT of the flock, an exact view, or examination of what cattle are in the flock; that it may be known whether it be overcharged, or not, and whose the beasts are; and whether they are commonable beasts, or not. See **FORREST**, and **COMMON**.

DRIFT, in Navigation, denotes the angle which the line of a ship's motion makes with the nearest meridian, when she drives with her side to the wind and waves, and is not governed by the power of the helm; and also the distance which the ship drives on that line, so called only in a storm.

DRIFT-sail, in a Ship, a sail used under water; veered out right a-head, by sheets, as other sails are: its use being to keep the ship's head right upon the sea, in a storm; and to hinder a ship's driving too fast in a current; with which view it is generally used by fishermen, especially in the North sea.

DRILL, in Mechanics, a small instrument for making such holes as *punches* will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths and turners.

It is a very well known fact, that a *drill* made of iron has frequently not only a polarity, but so strong an attractive virtue of the magnetic kind, that it will suspend a common needle from its point. It is usually supposed that a *drill* acquires this polarity by boring iron. But it is not only by boring of iron, that this power is obtained, but in the very making. As soon as one of them is finished and hardened, its point becomes a north pole before it has ever been worked either in iron or any other materials, so that of the great numbers of these instruments found in a shop, endued with this power, it is to be supposed that more of them owe it to their original make, than to any after use. All pieces of wrought iron which in shape resemble drills, that is, which are of a long and slender form, will not only have this polarity, but they will change it on being placed for some time in an inverted posture, and that which was the opposite to the north pole, by standing downwards will be the north pole. This has been an old observation, but on a fair experiment it does not prove to be true in all things without exception, though it is so in most particulars. The larger pieces of iron seem to be most easily influenced in their polarity, by changing their position; but the small ones will sometimes be found to have fixed poles, which no change of posture will alter. Phil. Trans. N° 236. See **MAGNET**.

DRILL, or **DRILL-box**, a name given to an instrument used in the new-method of horse-hoeing husbandry for sowing the land. See **BROAD-cast**, and **HUSBANDRY**.

The *drill* is the engine that plants the corn and other seeds in rows; it makes the channels and sows the seeds in them, and covers them with earth when sown, and all this at the same time, and with great expedition. The principal parts of the *drill* are the feed-box, the hopper, the plough, and its harrow. The feed-box is the chief of these; it measures or rather numbers out the seeds which it receives from the hopper, and is for this purpose as an artificial hand, that it delivers out the seed much more equally, than that can be done by a natural hand. The plough and hopper are drawn by a horse, and by these the ground is opened, and the seed is deposited in it; the harrow follows, and lightly rakes in the earth over them. When the ground is fine, and the seeds small, a hurdle with some prickly bushes fastened to its under part will serve better than the harrow. The whole apparatus for this method of sowing is described and illustrated with figures by Tull in his *Horse-hoeing Husbandry*. See **DRILL-PLUGH**.

DRILL-rule, in Husbandry. See **DRILL-RULE**.

DRILLING is popularly used for exercising soldiers. The word is derived from the French *drille*, which signifies a row soldier.

DRINK, a part of our ordinary nourishment, in a liquid form, serving to dilute and moisten the dry meat. The drinks, in different countries, are different. Those used among us, are water, malt-liquors, wine, cyder, punch, brandy, tea, &c. See each under its proper article, *CYDER*, &c.

The *malt-drink* brewed in England, in one year, Chamberlayne assures us, amounts to very near two millions of barrels, strong and small.

The first drinks of mankind were certainly water and milk; but luxury soon introduced the art of preparing intoxicating and inebriating drinks out of vegetables. The vine gave the first of these liquors; after this wheat, barley, millet, oats, rice, apples, pears, and pomegranates; and after these the juices drained from the pine, sycamore, and maple were brought to this use; in latter times, roots, berries, and the pulp of the sugar-cane, have been employed for the same purpose. Honey also is at present in some repute; but before the use of the other things here mentioned, the vinous liquor made of honey and water was in the very highest estimation. The bees were natural purveyors, and their stores were one of the first delicacies probably of the human race. It was very natural to attempt the meliorating of so raw a drink as water, by an addition of this sweet substance; and such a mixture needing only time for fermentation to become vinous, accident might soon lead to this discovery. Mead therefore may naturally be supposed to have been one of the first strong liquors in use in the world; and among the very oldest writers among the Greeks we find it named as a thing well known. Homer, Hesiod, and Aristophanes, all give plain proofs of their having been acquainted with it. The people who have studied the human frame to most purpose, all agree, that amongst the strong drinks, wine is the most pernicious; and that good water, milk, beer, and cyder, are greatly preferable to it, none of them bringing on the variety of disorders, to which immoderate wine-drinkers are subject, such as decay of sight, trembling of the limbs, &c.

Water, Dr. Cheyne observes, is the only simple fluid (for there are but three more in nature, mercury, light, and air, none of which is fit for human drink) fitted for distilling, moistening, and cooling; the only ends of drink, appointed by nature; and happy had it been for the race of mankind, had other mixed and artificial liquors never been invented. Water alone is sufficient, and effectual, for all the purposes of human wants in drink. Strong liquors were never designed for common use. They were formerly kept here in England, as other medicines are, in apothecaries shops, and prescribed by physicians as they do disacordium, and Venice treacle, to refresh the weary, strengthen the weak, and raise the low-spirited. The effect of the ordinary use of wine, and spirituous liquors, as natural causes will always produce their effects, is to inflame the blood into gout, fluxes, and rheumatism, fevers, pleuritis, small-pox, &c. to dry up the juices, and parch and thicken the solids. Those whose appetite and digestion are good and entire, never want strong liquors to supply them with spirits; such spirits are too volatile, and fugitive, for any solid or useful purpose of life. Two ounces of flesh-meat, well digested, beget a greater stock of more durable and useful spirits, than ten times as much strong liquors.

All strong liquors are as hard to digest, and require as much labour of the concoctive powers, as strong food itself. Water is the only universal solvent, or menstruum, and the most certain diluter of all bodies proper for food. There are a great many spirituous liquors, which not only will not dissolve, but which will harden, and make more indigestible, certain parts, especially the salts of bodies, wherein their active qualities, that is, those which can do most harm to human constitutions, consist. And we have known persons of tender constitutions, who could neither eat, nor digest, upon drinking wine, who, by drinking at meals common water, warmed, have recovered their appetites, and digestion, and have thriven, and grown plump. It is true, strong liquors, by their heat, and stimulation on the organs of concoction, by increasing the velocity of the motion of the fluids, and thereby quickening the other animal functions, will carry off the load that lies upon the stomach, with more present cheerfulness. But then, beside the future damages of such a quantity of wine to the stomach, and the fluids, by its heat, and inflammation, the food is hurried into the habit unconcocted, and lays a foundation for a fever, a fit of the colic, or some chronic disease. Essay on Health, &c. p. 47, & seq.

With respect to fermented liquors, which are commonly used, it may be observed, that those which are too strong hurt digestion, and are so far from strengthening the body, that they weaken and relax it. They keep up a

constant fever, which exhausts the spirits, heats and inflames the blood, disposes to numberless diseases, and occasions a premature old age. But fermented liquors may be too weak, as well as too strong; these must either be drunk new, before the fermentation is over, and in this case will generate air in the bowels, and occasion flatulencies; or they soon become stale, sour the stomach, and injure digestion. On this account all malt-liquors, cyder, &c. should be sufficiently strong to keep till they are ripe, and then they should be used; and neither sooner nor later. Liquors that are adulterated with a mixture of ingredients of the opiate kind, which are poisonous in their quality, by those who make them for sale, hurt the nerves, relax and weaken the stomach, and spoil its digestive powers.

DRINKING-GLASS. See GLASS.

DRINK-LEAN, in our *Old Writers*, a foot ale or contribution of the tenants towards a potation, i. e. ale provided to entertain the lord or his steward. In some records it is written, *potata drinkin*.

DRIP, in *Architecture*. See LARMIER.

DRIPS is also used in building, for a kind of sleep, on flat roofs, to walk upon.

This way of building is much used in Italy; where the roof is not made quite flat, but a little raised in the middle; with *drips*, or steps, lying a little insulating to the horizon. See ROOF.

DRIVE, in the *Sea Language*. A ship is said to *drive*, when an anchor being let fall, will not hold her fast, but that she falls away with the tide, and wind.

The best way to prevent this, is to veer out more cable; for the more cable she has, the faster, and safer the ride; or else to let fall more anchors.

Also, when a ship is a-hull, or astrey, they say, the *drives* to leeward, or in with the shore, according to the way she makes.

DRIVE-JACK, in *Ship Building*. See BOLTS.

DRIVER, the name given by our sportsmen to an instrument used in taking pheasant-pows, in the method called *driving*. This instrument consists only of a parcel of ozier wands, such as are used by the basket-makers, which are made up into a bundle, or sort of great whiff, and fastened in a handle; and to prevent their spreading too much at the points, are tied round in one or two places in the length; with this instrument the sportsman having fixed his nets, drives the young birds into them. See DRIVING.

DRIVER, in a *Ship*, is an oblong sail, occasionally hoisted to the main-peak, when the wind is very fair. The lower corners of it are extended by a boom or pole, thrust out across the ship, and projecting over the lee-quarter.

DRIVERS, *wind*. See WIND.

DRIVING, among *Sportsmen*, a term applied to the taking of young pheasants, and some other birds in nets of an open structure. The method of doing this is, when an eye of pheasants is found, the ground all about is to be searched, for finding their principal haunts. The industrious searcher will soon be able to make out some one of their paths, which are beaten in the manner of sheep-tracks, only more slightly. When one of these is found, the place is to be marked by setting up a stick with another tied to its top, like the hand of a road post, marking out the place where the path seems to run to. On examining the bell of the ground, thereabouts, having regard to the same direction, it is highly probable, that several more of the same sort of tracks will be found all running the same way. By one or other of these probably the sportsman will be led to their haunt, which he will not miss knowing by the nakedness and barrenness of the ground, and its being covered with the dung and feathers of the young birds. When this is found, the nets are to be placed near this spot, loose and circularly, in such a manner, that the under part being fastened down to the ground, the upper part may be hallowed, and give a passage to the young birds in, and entangle them when there. When the nets are fixed, the person must go to the haunts, and call them together by the artificial noise of the pheasant-call, which is to be like the real note of the pheasant, that the young, or young ones, will seldom fail being deceived by it. When they hear this, and begin to answer it with their chucking and piping, the call is to be stopped, and a person is to get behind them, taking the wind with himself, so they always run with the wind. He is to have in his hand the instrument called by the sportsmen a *driver*.

When the person who carries this instrument perceives that he is come pretty near some of the points, he must softly beat the bushes with the *driver*, or only lightly draw it over them; the little noise this makes will terrify these timorous creatures, and they will gather together in the track, and run a little way forward, and then all

stop and turn about, on this the person is to make the same noise again, upon which they will run farther; and when they stop again, the same noise will again send them forward. Whatever other points are in the way will join the main body in this fright, and the whole will be driven in this manner, like a flock of sheep, and by a little address of the sportsman be sent into the nets; so that out of a whole eye, it often happens that not one is missed. If in the fright the birds happen to run out of their track, and take a wrong way, then the driver is to make a raking noise with his instrument dragged along the ground, on that side on which they are running; this will amaze and terrify them so, that they will immediately flit back, and come into the beaten track that leads directly to the hunt. There are but two cautions necessary to the succeeding perfectly in this method of taking them: these are secrecy and patience. Whatever stops they make, or however tediously they move, the sportsman who would make sure of them, must bear with it; for over-rashness and hurrying will spoil all, and he must content himself with terrifying them by the noise alone, keeping himself carefully out of their sight; for if they spy him, all the plan is disconcerted, and they will no more move forwards, but will every one run a different way, and hide under the roots of trees, and thick bushes, and all the art in the world will never bring them out again till night, when it will be too dark to watch them.

DRIVING of wild fowl, is only practicable in the moulting time, which is in July and August; and it is to be done by means of a spaniel, well trained to the purpose. The nets are to be set in creeks and narrow places, or at their usual night retreats, and the dog is to get them up, and driving them forward, they will be sent immediately into the nets, not being able to fly away from the dog, from the want of their wing feathers. The people who live in the fens find great account in this practice, taking very great numbers of wild-ducks by it. They are usually indeed poor and out of flesh at this time, but as they are always taken alive, and without any hurt, the people find it easy to fatten them with beets, livers, barley, pale, scalded bran, and the like; and they will on this become, in a very little time, fat and well tailed, excelling in flavour both the tame ducks commonly kept in the yards, and the wild ducks in their natural state. When the sportsman takes the dog into places where they are not so frequent, he may hunt them singly, and the dog alone will take them.

DRIVING, in Metallurgy, is used by the refiners of silver, to express the rising up of copper from its surface in red fiery bubbles. When the lead that was added for refining the silver is burnt away before the copper is gone from it, these bubbles appear very fiercely on the surface. They say, on this occasion, that the metal drives, and then add more lead, till the remainder of the copper is consumed. Phil. Trans. No. 142.

DROCK, in Husbandry, a name given by our farmers to a part of the common plough. It is an upright piece of timber, running nearly parallel with the hinder part of the plough, but belonging to the right side of the tail, as that does to the left. The ground with of the plough is fastened to this, as also is the cart-board. See WHIST, EARTH-BOARD, and PLOUGH.

DROFFAND, or DRYEAND, in our Old Writers, was a quittance or yearly payment made by some tenants to the king or their lordships, for driving their cattle through the manor to fairs or markets.

The word comes from the Saxon *dryfena*, driven.

DROGMAN. See DRAGON.

DROIT, Jus, in our Law-Books, signifies right, or law; whereto some distinguish Ex rights, viz. 1. Jus recuperandi, right of recovering. 2. Jus utendi, right of enjoying. 3. Jus habendi, right of having. 4. Jus retinendi, right of retaining. 5. Jus precipuendi, right of receiving. 6. Jus possidendi, right of possessing. See LAW, and RIGHT; as also RECTUM, ENTRY, POSSESSION, &c.

DROIT, Right, gives name to the highest writ of all real writs, because the greatest regard is paid to it, and it has the most assured and final judgment. Of this kind are the writs of *ad iudicium*, &c.

DROIT, *droit*, See RECTO.

DROIT, *droit*, See RECTO de Associatione Ecclesie.

DROIT, *droit*, Jus Duplication, or double right, is the right of possession, joined with that of property; and when actual possession is united to this double right, then a title is completely legal.

DROIT, *droit*, See RECTO de iure.

DROIT, *droit*, See RECTO.

mel, which has only one bunch on his back. Its hairs are soft to the touch, and are shorter than those of our oxen, except that there are some longer on the head, the throat, and the top of the back; and on the middle of the back there are hairs of a foot long, which, though very soft and flexible, yet naturally standing in an erect posture, make the most visible part of the bunch. For when these are removed by the hand, the flesh scarce appears more prominent, than that of the back of a hog, and there is not the least scaly or callous excrescence there.

The head is small in proportion to the body; the upper lip is divided as in the hare; the feet are not hooved, but each terminated by two small claws; the sole of the foot is broad and very fleshy, and seems soft to the touch, though the skin is very hard and callous; the feet are indeed clothed as it were with living shoes, which are of very great service to it in travelling over the sandy countries. It has six callous hardles on the knees and shoulders of the forelegs; and one on each of the hinder ones. And beside these, there is another much larger, which adheres to the breast, on an eminence which is there, as if made to support it; this is usually eight inches long, six inches broad, and about two thick. The use of these is to sustain the weight of the creature's body on occasion of his flopping to rest, or to be loaded.

Its stomach is very large, and divided into four parts as in other of the ruminating animals, but of a singular structure; because, at the upper part of the second ventricle, there are several square holes, which are the offices of a great number of a sort of bags, placed between the rumblings which compose the stomach, and these seem to be the receptacles of water kept for the time of necessity; for the creature always drinks a vast quantity at once, and will then live a great while without drinking again. It is yet a question to be decided, whether this creature is of the retromingent kind; and whether it copulates backwards? This has been affirmed by some, but it is greatly doubted by others. See Tab. of Quadrupeds, No. 1. and CAMEL.

The *drumery* is swift, and is trained in Arabia for races, and in some places for carrying coitons, who can travel above a hundred miles a day on them, for nine days together, over burning deserts, unobtainable by any living creature. Ray and Leo Afric. 320.

DROMEDUS, from *ῥῆμα*, I run, in Natural History, a word used by the ancients, as the name of two very different animals, the flag and the dromedary. The meaning of the word is *swift in running*; and the flag had this name as being faster than any other animal, and the dromedary as being swifter than any of the camel kind beside.

DROMONARI, in Antiquity, towers belonging to the ships called *dromon*.

DROMONES, in Antiquity, a kind of rafts or expeditionary ships used in carrying provisions, or other necessities. Philo. Lex. Ant. in voc.

DROMONS, **DROMOS**, or **DROMENIA**, in middle age writers, signified any large ship; but afterwards it was used chiefly for men of war; and in this sense it is used in Wallingham, anno 1292, and in Knighton, lib. iii. cap. 14, &c.

DRONE, in Music. See BUBBON.

DRONE, in Natural History, a sort of bee of a larger size than the common working bee, which being unprovided with the necessary apparatus, never goes out to work, in collecting either wax or honey, but lives on the honey collected by the rest. These are the males of the swarm; the common working bees are of no sex at all, or rather females in disguise, and the female is usually only one in a hive; for there is reason to conclude, from numerous late experiments, that the queen-bee lays only two kinds of eggs, those that are to produce *drone*, and those from which the working bees are to proceed. The proportion of *drone* to other bees in swarms is various; some having more than others. See QUEEN-BE.

This larger species of *drone* may be easily distinguished from the working bees, by being nearly double their size. Their head is round, their eyes full, their tongue short, and belly broader and more obuse than that of the other classes; they are likewise of a darker colour, and more thickly clothed; and they make a much greater noise in flight, so that they may be easily known, though unseen. They have also no sting, as the other bees have.

The dissection of the *drone* bee gives a great proof of its being the male, as that of the queen does of her being female. In this creature there is no appearance of ovaries or eggs, nor any thing of the structure of the common working bees, but the whole abdomen is filled with transparent vessels, winding about in various capacities, and containing a white or milky fluid. This is plainly analogous to that fluid in the males of other ani-

male, which is destined to render the eggs of the female prolific; and this whole apparatus of vessels, which much resembles the turnings and windings of the female vessels in other animals, is plainly intended only for the preparation and retention of this matter, till the destined time of its being emitted on the eggs. At the extremity of the tail ring of the body, is placed the aperture of the anus in the female, and in the working bees; and it is at this aperture, that the sting is also thrust forth; but the case is quite otherwise in the *drone* or male bee; for the extremity of that ring is not open, but absolutely closed; and the aperture of the anus is in the under part of that ring about its middle. On pressing the body of this bee, there is also forced out at this part the penis; this is a small and slender fleshy body, contained between two horns of a somewhat harder substance, which join at their base, but gradually part asunder as they are continued in length. When the penis is continued, there is finally thrust out at the same aperture a part of the internal apparatus of the female vessels, and, in fine, there is usually some of the milky liquor extruded; but this seems rather to be let out by the bursting of a vessel, than by any natural passage. These parts, found in all the *drone*, and none of them in any other bees except the *queen*, seem to prove very evidently the difference of sex; but there is one thing extremely remarkable in regard to them, which is, that though they appear to evidently on being forced out of the body by pressure, yet it is very difficult to find them in it on dissection. The cause seems to be their swelling when exposed to the air; and Swammerdam supposes, that to this purpose they are furnished with a great number of tracheae, which readily admit the air as soon as ever they are exposed to it.

Maraldi, as well as Swammerdam, discovered in the structure of the *drone* some resemblance to the male organs of generation, and from thence concluded that they were the males; but neither of these accurate and industrious observers could detect them in the act of copulation. Swammerdam, therefore, entertained a notion that the female or queen-bee was fecundated without copulation; that it was sufficient for her to be near the males, and that her eggs were impregnated by a kind of vivifying aura, exhaled from the body of the males, and absorbed by the female. However, M. Reaumur thought, that he had discovered the actual copulation of the *drone* with the female bee, and he has very minutely described the process of it. Hist. Insect. tom. 3. p. 128. 129.

Nevertheless, many of the ancients, as well as moderns, have supposed that the eggs of the female bee are not impregnated with the male sperm, while in the body of the creature, but that they are deposited unimpregnated in the cells, and that the male afterwards ejects the male sperm on them, as they lie in the cells; in the same manner as the generation of fishes is supposed to be performed by the males impregnating the spawn after it is cast out by the females.

M. Maraldi long since conjectured that this might be the case; and he was confirmed in the opinion, by observing a liquid whitish substance surrounding each egg at the bottom of the cell, a little while after it had been laid; and that a great number of eggs, which were not accompanied by this liquor, remained barren in the cell. Hist. Acad. Sc. 1732. p. 322. See Generation of Bees.

This method of impregnation has been lately established beyond all contradiction by the observations of Mr. Dehraw of Cambridge. Having put some bees into glass-bibles with a large number of *drone*s, he observed on the first or second day (always before the third) from the time in which the eggs were placed in the cells, which the queen generally lays on the fourth or fifth day after they are put into the hive, that a great number of bees gathered themselves to one another, and formed a kind of curtain from the top to the bottom of the hive, probably in order to conceal the process of generation. Mr. Dehraw, however, could soon perceive several bees, whose size he was not able to distinguish, inserting the posterior part of their bodies each into a cell, and sinking into it; after a little while they retired, and he could see with the naked eye a small quantity of whitish liquor left in the angle of the base of each cell, containing in eggs; this liquor was less liquid than honey, and had no sweet taste. See Generation of Bees.

In order (rather to ascertain the fact, that the eggs are thus fecundated by the males, Mr. Dehraw took a swarm of bees, and having separated the *drone*s, by shaking all the bees into a tub of water, and leaving them in it till they were quite senseless, replaced the working bees and their queen, as soon as they were recovered, by spreading them on a brown paper in the sun, in a glass hive. The queen laid eggs, some of which, at the end of

twenty days, were hatched into bees, others withered away, and several of them were covered with honey. Suspecting that some of the males, having escaped his notice, had impregnated only part of the eggs, he was anxious to ascertain the fact; and with this view he removed all the brood-comb that was in the hive, and determined to watch the motions of the bees after new eggs were deposited in the cells. On the second day he perceived the operation, already related in a former case, and on taking out a piece of the comb, containing two of the bees which had thrust the posterior part of their bodies into the cell, he examined them, and found that they had no sting; and upon dissection he discovered in them, by the help of a microscope, the four cylindrical bodies, containing the whitish liquor above described, which Maraldi has observed in the large *drone*. In a subsequent experiment, Mr. Dehraw separated from the same parcel of bees all that had no stings; and he found no less than fifty-seven of the number exactly of the size of common bees, which on being pressed between the fingers, yielded a small quantity of whitish liquor. Having killed all these, the remainder of the swarm was returned to the hive. On the fourth or fifth day, the queen deposited her eggs in the cells; but no part of the process of impregnation could be discovered; the eggs, after the fourth day, instead of changing in the manner of caterpillars, remained in the same state they were in the first day, except that some of them were covered with honey: all the bees left their hive, and attempted to get into a neighbouring hive, probably in search of males; but the queen was found dead, having been killed in the engagement. Mr. Dehraw made another experiment, which must be considered as an experiment *cruci*, and absolutely decisive on this subject. He took a part of the unimpregnated brood-comb, and placed it under a glass bell, in which he confined a queen, and some common bees, without any *drone*s; the other part of the same brood-comb he put under another glass bell, with a few *drone*s, a queen, and a number of common bees. In the former glass the eggs remained in the same state; there was no impregnation; and when the bees were released on the seventh day, they all flew away. The *drone*s, in the other glass, were observed to impregnate the eggs in every cell, on the day after they were put in; the bees remained in the hive, and in the course of twenty days every egg underwent the necessary transformations, and a numerous young colony was thus produced. Phil. Trans. vol. lxxiii. part. 1. art. 3. See Queen-Bees.

Maraldi and Reaumur had long ago discovered, that there were *drone*s of the same size with the common bees; but these curious experimenters, besides ascertaining the fact, throw new light on their importance and use, and remove considerable difficulties, which embarrassed the process of generation among these useful insects. It is well known that the large *drone* never appears in the hive before the middle of April, and that they are all dead before the end of August, when the principal breeding season terminates; and they are destroyed, together with all their worms or nymphs, by the working bees, probably by order of the queen to save honey; and yet it is equally certain that the bees begin to breed early in the spring, sometimes in February, if the weather is mild; and that many broods are completed before these *drone*s appear. But if *drone*s of a smaller size are suffered to remain, which in a time of scarcity consume less honey than the others, these will answer the purpose of supplying the early broods, and the larger *drone*s are produced against a time of greater plenty.

An ingenious friend of the editor, who amuses himself with observing the economy of bees, and who has long since discovered the small *drone*, and from whose amusements the world may probably derive useful information with regard to these insects, assures him, that these smaller *drone*s are all dead before the end of May, when the larger species appear, and supersede their use. It was not without reason that a modern author suggested, that a small number of *drone*s are retained to supply the necessities of the ensuing year; and that these *drone*s are very little, if at all larger, than the common bees. Nat. Hist. p. 96.

Drosophila, or *Bee-fly*, is a two-winged fly, so extremely like the common bee as to be at first sight not easily distinguishable from it. The distinction between the two insects, however, beside the different number of their wings, is, that the bee has a somewhat longer and less thick body, and the head is proportionably much smaller than that of the fly which so much resembles them. The *bee-fly* also ever carries its wings parallel in their position, but without its body; whereas the bee itself usually carries its wings crossed on the back, and covers its body with them; this is not however an invariable postu-

ture with the wings of the bee, though it is the most frequent one. The *bee fly* is found among the flowers, as is the bee; and though it galleys no wax, it has a trunk by means of which it sucks the honey.

The trunk, by means of which the fly is enabled to do this, has no teeth, and consequently the fly belongs to Mr. Reaumur's first general class of the two-winged flies; and the form of its body, which is short and flat, determines it to be of his first subordinate genus of that class.

The most singular and observable part of the life of this insect is that which it passes without wings, and in form of a fly-worm or nymph. The general exterior form of the fly-worm of this genus has been well enough known to the generality of naturalists; and Goodart, Merian, and Albinus, were well acquainted with them so far; but they did not give themselves the trouble of a farther examination, and were not sensible that these worms had many observable things to offer to our consideration.

The matter among which they are found is that of all others the most offensive and disagreeable. They are of the class of those with variable heads; but the great distinction from all others is their having a long slender tail. This at different times the worm makes of very different lengths, but in its shortest it is longer than the body of the creature. It is round, smooth, and at times extremely small at the extremity, and sometimes much resembles the tail of a rat; whence the whole class of these worms are well distinguished by the name of rat-tailed worms.

To know the use of the tail of this worm, it is however necessary first to understand the nature of the worm itself. These worms being usually found on dry land, and only picked up now and then (scarcely) gave the world for a great while no room to believe that they were so numerous as they really are; nor had people any idea that they were to look for them in the water. In examining vessels of corrupted and stinking water, however, they have been found in very great multitudes together, lying among the mud at the bottom. These taken out of this filth, and put into vessels of clean water, will soon show the curious observer the use of their long tails. Notwithstanding that these worms are to live under water, and in mud, there is no doubt to be made but that, like other of water-fly-worms, they have a necessity of breathing fresh air; and it is to this great purpose that their long tail serves them; for while they lie buried in the mud, this is extended up to the top of the water, and being open at the extremity lets the air into the body of the creature. It is a pleasing sight to observe, that these animals, after having been put into a vessel of fresh water, all get quickly to the bottom, and each thrills up the extremity of its tail to the surface.

It is very easy, from seeing that at whatever depths the worms lie, their tails still reach the surface, to conclude, that they have a power of lengthening them at pleasure. The ready way to be assured of this is to add depth to the water, by pouring more into the vessel; for as the worms love the bottom, they must, if they will remain there, lengthen their tails proportionably, in order to breathe from the surface. The repeating several of these additions, shews, that the worm is able to extend its tail to the length of five inches; an extremely remarkable length for a creature, whose body is not much more than half an inch, and whose tail in its more common state is not much longer than that. Five inches are however the limit, beyond which they cannot go in this action; and when the water in the vessel is made of a greater depth, the worms leave the bottom, and either crawl up the sides of the vessel to a proper height, or else swim in the water at the depth of five inches, which is the depth at which they carry their tails up to the surface.

The organization of so remarkable a part as the tail of this animal, cannot but appear to the curious greatly worth the enquiring into; and the transference both of it, and of the body of the creature, is such as to favour very greatly this examination. And indeed in many of the younger of these worms, and such as have not yet come to the state at which they quit the water, one may distinguish the parts within the body as plainly almost as if placed for examination in a glass tube. It is easy in all stages of the worm to distinguish that the tail is composed of two hollow tubes, the one of which nicely fits, and is easily retracted within the other, or thrust out of it again, as the creature's occasions require. The outer and larger tube seems an elongation of the fleshy matter that forms the rings of the body. It is white like the body, and is composed of a vast number of rings, as the body is. Within this is lodged a stiffer pipe, a great part of which is of a blackish brown; and by means of this colour the inner tube may be distinguished, even when it is wholly within the other. This inner one may be

called the tube of respiration. It is easy to see now that the tail of the worm may be made more and more long, as his inner tube is thrust out of the other, which serves it as a case or sheath. But this is not all; it is easily known that these pipes are in themselves capable of extension, by observing, that when the whole inner tube is lodged within the case, or outer one, yet this is of no determinate length, but is sometimes longer, sometimes shorter.

Many of the water-fly worms do not quit that element till they arrive to the fly state; but this species, as soon as they have acquired their full growth, leave the water and crawl upon the earth. Their bodies in this new element become dirty and greyish; and when they have found a proper spot of ground where the earth is soft and moist, they bury themselves, and after a necessary time for their change, come out in the form of flies.

Their changes are all made under a shell of their own skin, which in a few hours is found beginning to harden, and by degrees becomes very firm, of a yellowish colour, and is remarkable for having four horns, two larger and two smaller, placed in different directions near the head; and these are the organs of respiration to the encased nymph.

These are the changes of the flies of this class. They are of several species, and differ in size not less than the worms from which they are produced. Of these the largest are found in vaults and privies; and in winter, multitudes of them may be met with in the hollows of willows, and other trees where there is water. Reaumur. **DROITE**, in *Ornithology*. See **DONO**.

DROPAX, *Δροαξ*, in *Pharmacy*, an external medicine, in form of a plaster, used to take off the hairs from any part. See **HAIR**, and **DEPILATORY**.

The *dropax* is of two kinds, *simple* and *compound*. The *simple* is made of an ounce of dry pitch, and two drachms of oil.

The *compound* is made with pitch, wax, colophony, common salt, bitumen, sulphur vivum, pepper, euphorbium, cantharides, and castor. There are also other ways of making it, to be found in the different authorities.

It was anciently much in use also to *scrape* the parts, to draw the blood and spirits to them, and to cure asthenia. To this purpose it was applied not on the part affected, after first shaving it; and was pulled off again before it became quite cold; then heated afresh, and applied again; and the operation thus repeated, till the part was rendered very red.

DROPPING, or **DRIPPING**, a term used among *Falconers* when a hawk mutes directly downwards, in several *drops*, not throwing out her dung, straight forwards.

DROP, in *Sea-Language*, is a name sometimes given to the depth of the principal falls; thus, a main-topfall drops seventeen yards.

DROPS, in *Architecture*. See **GUTTA**, and **TALOTYUM**. **DROPS**, in *Medicine*, a liquid remedy, whose dose is estimated by a certain number of drops.

DROPS, in *Astronomy*. See **RAINS**.

The spherical figure, into which the *drops* of fluids conform themselves, is a phenomenon that has a little perplexed the philosophers. The solution commonly given was, that the equable, uniform pressure of the ambient, or incumbent atmosphere, closed them into this form. But this account will no longer pass; now that we find that the phenomenon holds in *vacuo* as well as in air.

The Newtonian philosophers, therefore, ascribe it to their *attraction*, which being greater between the several particles of the fluids, than between them and those of the medium, they are, as it were concentrated, and brought as near each other, and into as little compass, as may be; which cannot be, without their being spherical.

Thus, Sir Isaac Newton: *Gutta enim superior exigua fluidi, et figuram globulæ inducere cœperunt, facti minores partem suam attrahunt, etiam modo quo terra marisq; in rotunditatem undique conglobantur, partem suam attrahunt minus, quæ est gravitas.* Opt. p. 338.

DROPS, *English*, or *soluble English drops*, *Gutta Anglica*. See **GUTTA ANGLICA**.

DROPPER. See **FISHING**.

DROPSY, *ῥιψα*, in *Medicine*, a preternatural collection

of serum, or water, in some part of the body.

The word is compounded of the Greek *ῥιψα* water.

The *dropsy* acquires different names from the different parts it affects, or the different parts the waters are collected in. That of the abdomen, or hypochondria, is called simply, and absolutely, *dropsy*, is *πνεῦμα* *ascites*, named *ASCITES*. That of the whole body of the body, in which a serous humour is collected through the cellular system, and lodged under the skin, is called *ANASARCA*, or *inflammation*. That of the head, *HYDROCEPHALUS*. That of the thorax, *HYDROTHORAX*. There is also a species of this disease, supposed to be caused, instead of water, by a collection of wind, called *symphysis*.

tympantitis, and by Hippocrates, the *dry dropsy*. See EUPHYSEMA.

We also meet with *dropsy* of the breast, lungs, pericardium, ovaries, uterus, &c. Some think that the anasarca, leucophlegmatia, hydrops ascites, tympanitis, hydrocele, &c. differ so exceedingly little, that it is scarce worth while to retain for many pompous Greek names. Medic. Ess. Edinb. vol. i.

The general cause of all *dropsies* is the exhalent vessels throwing off more fluid than the absorbent vessels can take up; and the remote causes are whatever may obstruct the serous part of the blood, so as to make it stagnate in the vessels; or burst the vessels themselves, so as to let the blood out among the membranes; or weaken and relax the tone of the vessels; or thin the blood, and make it watery; or lessen the perspiration, and the vital heat.

These causes are various; viz. sometimes acute diseases, scirrhus tumors of any of the more noble viscera, excessive evacuations, particularly hemorrhages, and remote fluxes of the belly, suppression of customary evacuations, as the menses, hemorrhoids, &c. want of exercise, hard drinking, especially of spirituous liquors, drinking of cold, weak, watery liquors, after having been accustomed to liquors of a more generous kind, or when the body has been heated by violent exercise, the use of aliment that is viscid, and hard of digestion, living in a low, damp, marshy situation, &c.

The ascites, or *water-dropsy* of the abdomen, is the most usual case, and what we particularly call the *dropsy*. In this disorder, the water is accumulated in the cavity of the belly, between the peritonium and the viscera, in the dilated cavities of the glands, or other vessels contained in the abdomen, or in the duplicature of the peritonium: its symptoms are tumors, first of the feet and legs, and afterwards of the abdomen, which keep continually growing, and if the belly be struck, or shaken, with one hand, whilst the other hand is placed on the opposite side, there is heard a quashing of water. And to this three other attendants, viz. a dyspnoea, intense thirst, and sparging urine; with which may be numbered heaviness, listlessness, costiveness, a slight fever, and an emaciation of the body.

This species of *dropsy* should be carefully distinguished from pregnancy, excrecences, and other tumors in the belly, and from a tympany. In young and strong patients, this disease, if taken betimes, may admit of a cure; but if the patient be old, or has led an irregular, or a sedentary life, or if there be any reason to suspect that the liver, lungs, or any of the viscera, are unsound, there is ground to fear that the consequences may prove fatal. When the anasarca and ascites are combined, the case is very dangerous.

The curative indications are two: viz. the evacuation of the water, and the strengthening of the blood and viscera. The first is effected by strong purgatives, particularly elaterium, and the infusion of crocus metallorum, though this last works upwards more than downwards. Purgings medicines of different kinds will be required for different patients, and for the same patient at different times; but, in general, for the stronger, calomel and jalap; and for the weaker, calomel and rhubarb will be proper. Occasional doses of ipecacuanha in powder, and oxymel of squills, may be likewise administered as emetics.

But if the disease proceeds from a bad habit, or an unsound state of the viscera, strong purges and vomits should be avoided, and recourse be had to such medicines as will palliate the symptoms, by promoting the secretions, and to warm nourishing cordials for supporting the patient's strength. For such as are too weak to bear purgatives, Dr. Sydenham recommends diuretics, whereof the best are those made of the lixivial salts; to which hellebore may be joined, for increasing their effects.

Dr. Baker's tonic pills have been celebrated in *dropsies*, both as diuretic and purgative. The recipe for preparing them is as follows:

R. Extract. helleb. nigr. myrrhæ solut. aa ʒi. card. bened. pulv. ʒiii. & ʒi. m. f. massa siccæ sicco excandat: donec formandis pilulis apta sit; singul. ad gran. senilid.

These pills have been given in different numbers, up to thirty, for a dose, taken by ten at a time, and an hour between each portion.

The following diuretic infusion, taken every four or five hours a day, may be of considerable service: take juniper berries, mustard seed, and horse-radish, of each an ounce; infuse them in a quart of Rhenish wine, or strong ale, for a few days, and strain off the liquor. Or, take of zedory root, two drams; dried squills, rhubarb, and juniper berries bruised, of each a dram; cinnamon in powder, three drams; salt of wormwood a

Vol. II. N° 102.

dram and a half; infuse them in a pint and half of old hock wine, and filter the liquor; and let a wine glass of it be taken three or four times a day.

Nitre, taken in the quantity of a dram every morning, has produced a very good effect; and the same diuretic purpose may be answered by six or eight grains of the powder of squills, with a scruple of nitre, administered twice a day in a glass of strong cinnamon water. Others have extolled the efficacy of a large spoonful of unbruised mustard seed, taken every night and morning, with half a pint of the decoction of the tops of green broom drank after it. Cream of tartar, the doses of which may be gradually increased to two or three ounces a day, have been useful in some cases.

The decoction of feneka root, or Mindererus's spirit, taken in a dose of two table spoonfuls, in a cup of wine, three or four times a day, will promote perspiration. Dr. Percival, for this purpose, recommends rubbing the skin every night and morning with dry cloths, fumigated with camphor, and giving internally the julep and camphor; so that a dram of camphor may be taken in a day. Wainwright extols an infusion of green tea in Rhenish wine, and also briony juice, as excellent in this disease. Some also commend garlic.

Dropsies, attended with anasarca swellings, are not to be cured with purging alone, nor by soap, nor mercurials; but chiefly by the lixivial salts, either in the form of broom ashes, salt of wormwood, or salt of tartar. The common method is this; about thirty or forty grains of salt of tartar are dissolved in an infusion of wormwood, to which is added spirit of juniper; and this mixture is to be given in three doses and repeated daily. Besides this it may be proper to give the patient, once in four or five days, half a dram of *pilula ex coquevisula cum aloe*, as a purge; and toward the decline of the disease, some common chalybeate. The diuretics may also be promoted by swallowing garlic, or mustard-seed. See Pringle's Observ. on Diseases of the Army, p. 213.

Dr. Buchan observes, that he has known an obstinate anasarca cured by the infusion of broom ashes in wine. It may be observed in general, that when the water of an ascites is carried off by any other means than by a puncture through the peritonium, it is done by that operation of nature called ABSORPTION; and hence is derived the principal use of purgatives, sudorifics, and diuretics. Lond. Med. Obs. vol. II. art. 2.

For the second intention, exercise, and change of air, wine, and other generous liquors, also stomachics, chalybeates, and other corroborating medicines, are prescribed.

The diet should be dry and nourishing: the pungent and aromatic vegetables, as garlic, mustard, onions, horse-radish, &c. may be freely used. The best liquor is Spa water, or Rhenish wine. The patient should also have his body rubbed, two or three times a day, with a hard cloth, or the flesh brush; and always wear flannel next his skin.

Where other means fail for evacuating the water, recourse is to be had to the PARACENTESIS, or operation of tapping. This will, at least, prove a palliative; and if used soon enough may even effect a cure; but a delay is very dangerous.

Exercise is recommended to hydropic people immediately before tapping, that the grosser particles in the water of their belly may be mixed with the thinner, and so run out with them. And if there is reason to suspect any such gross parts remaining after the operation, some advise the injection of barley-water to dilute and bring them away.

We have lately had accounts, in the Philosophical Transactions, of *dropsies* cured by tapping, and afterwards injecting Cahor wine, mixed with Bristol water.

There is also an account of an uncommon *dropsy*, from the want of a kidney, in the Philosophical Transactions. The subject was a young woman; the water evacuated from the abdomen on dissection, measured near half a hoghead, and was contained in a large sack, which almost occupied the whole cavity of the abdomen above six feet in circumference, and extended upwards of four feet from the xyphoid cartilage to the os pubis. The figure and description of this sack, and the adjacent parts, may be seen in Phil. Trans. N° 482. sect. 2.

We read of an hydropic body becoming so infectious, that the surgeon who tapped the corpse, was thrown into a pestilential fever. Phil. Trans. N° 454. sect. 4.

Baglivi notes, that in a *dropsy* arising from a morbid liver there is always a vehement dry cough; which is never observed in any other species. In the appendix to vol. III. of Dr. Prießley's Observations, &c. on Air, p. 490. we have an account of the cure of a *dropsy* by the use of fixed air, after all other remedies had failed, and the patient had been tapped five times.

DROPSY of the breast, Hydrops Pectoris, arises from water extravasated in the breast on one or both sides of the mediastinum; or contained in *hydathides*, situated on the diaphragm, pleura, lungs, heart, or pericardium. This may be occasioned by a disorder of the lungs, or the rupture of a lymphatic, or by any of the causes of a common dropsy. Instances have rarely occurred in which the water hath been absorbed; but the disease is commonly very dangerous. When the water is perceived to fluctuate, it may be drawn off by a canula and trochar, introduced between the fourth and fifth of the false ribs, and about four fingers' breadth from the spine. See *Dran's Oper.* ed. 2. p. 117, 118. *Motherby's Dict.*

DROPSY emphyse. See *DROPSY of the lungs.*

DROPSY of the head. See *HYDROCEPHALUS.*

DROPSY of the knee, Hydrops Genu, is formed by water collected under the capsular ligament of the knee. Mr. Sharp recommends, for a cure, a tight bandage, leaving the superfluous to be absorbed by the bibulous veins; to which may be added some attenuating and discutient embrocations. *Goode's Cases*, &c. vol. ii. p. 259: 266. *Motherby.* See *SRINGA vesicula.*

DROPSY of the lungs, Hydrops Pulmonum, is seated in the cellular membrane of the lungs. This is a very uncommon disorder; but it has been sometimes observed by the physicians of our own nation. The most perfect account, however, any where given of this disease, is that of Mr. Malouet, of the Paris Academy, in the case of a poor invalid soldier, whom he had attended through all the stages of it. He had a very great difficulty of respiration, accompanied with a slow fever. When in bed he could neither lie with ease on either side, nor on his back; but was forced to lie upon his belly, and consequently, as that was a very troublesome posture, he usually took his rest in a chair. His hands and arms were much swelled, as were also his legs and feet, and his urine was of a brick colour. Mr. Malouet, from all these circumstances, suspected water in the breast, but was never able to perceive any fluctuation, into whatever change of posture he made the patient go, nor could he find that the man himself ever perceived any such sensation within him. The unhappy creature died, after two years illness; and his body being opened, there was no water found loose in the breast, but on each side of the lungs there was observed an oval tumor of six inches long, and four inches broad, they were both of the same size, and on touching them with the hand, there was a very sensible fluctuation observed. On opening these, water ran out in a large quantity; and on examining their structure, they were found encysted tumors, with considerably thick membranes, composed of several coats, or coats of matter, but with no blood-vessels distinguishable in them. Examining the liver, there was found another encysted tumor there, the contents of which were a lymph, tinged to a yellowish green by gall. *Mem. Acad. Par.* 1732.

This disorder may be relieved by a brisk mercurial cathartic, and liberal doses of the seneca root, and other diuretics and sudorifics. In a desperate case an opening may be tried, as in the operation for the EMPHYSEMA, and a puncture may be made into the lungs for discharging its morbid contents. *Edinb. Med. Ess.* vol. vi. p. 126. *Percival's Ess. Med. and Exp.* p. 172. *Motherby.*

DROPSY of the ovaries, Hydrops Ovarii, is of the encysted kind, and sometimes happens to pregnant women, but most frequently to the barren and superannuated. The patient in the commencement and first progress of this disease has neither bad health nor pain. It is not perceptible, while small, except in particular situations. At first it is commonly situated towards one side, in the lower part of the belly, and is moveable under the hand; then it becomes gradually more fixed, more extended both forwards and upwards in the belly, and more painful and oppressive to the patient. When the cyst is single, and extended over the whole abdomen, it cannot be distinguished by feeling from a common ascites; but when there is a number of cysts, the inequalities in the swelling are generally sensible from first to last. Dr. Hunter observes, that the dropsy of the ovarium is an incurable disease, and that a patient will have the best chance of living longest under it, who does the least to get rid of it. He is of opinion, that the trochar is almost the only palliative; and that a radical cure by the excision of the cyst can hardly be attempted; and that incision and separation are operations which cannot be recommended, but under very particular circumstances, and that they change the dropsy into an incurable fistula in the belly. The disorder generally terminates in a universal leucophlegmatia. However, Dr. Percival gives an instance of a cure being effected by a spontaneous vomiting. *Lond. Med. Obs. &c.* vol. ii. p. 41, &c. *Percival's Ess. Med. and Exp.*

DROPSY of the scrotum and testis. See *HYDROCELE.*

DROPSY of the womb, Hydrops Uteri, is seated in the cavity of the womb. It is distinguished from the ascites, by being confined to the region of the uterus, and by the thinness of the *serosa tunicæ*. When it proceeds from a fibrinous, it is never in the middle, nor is it round, as in the common dropsy. A canula introduced into the womb promotes the best and speediest remedy; but this is sometimes prevented by a fibrinous, cicatrix, or tubercles; in which case recourse may be had to hard riding, emetics, sturnatories, and brisk cathartics. Borax may be given from ten to twenty-five grains twice a day as a deobstruent, and a pessary may be also tried. *Motherby*, and *Jamieson*, art. *HYDROPS.*

DROPWORT, in Botany. For the characters, see *SPERMATOPHYTES.*

The common dropwort grows plentifully upon chalky grounds in many parts of England. The roots consist of a great number of oval knobs or glandules, which are fastened together by slender fibres, from whence it had the name of *droppwort*. The leaves are winged, and composed of many sawed lobes, which are almost placed alternately along the mid-rib. Those near the base are the smallest; the others increase in size to the middle and decrease afterward again to the point. The flower-stalk rises a foot or more in height, and has seldom more than one leaf upon it; the top is garnished with loose bunches of small white flowers, standing upon slender foot-stalks, which are succeeded by several capsules ranged circularly. The roots of these plants are used in medicine, and are accounted diuretic. It is rarely kept in gardens; but there is a variety with double flowers, which was found growing naturally in the north of England, that is kept in gardens for the sake of variety. They are propagated either by suckers, which they produce in great abundance, or by laying down the tender branches of the old plants. When they have taken root they should be removed into the nursery for two or three years, and will then be fit for transplanting in the places where they are to remain.

DROPWORT Water, Oenanthe, in Botany, a genus of the *pentandria digynia* class. Its characters are these: it is a plant with an umbelliferous flower; the principal umbel has but few rays, but the particular umbels have many short ones; the rays of the principal umbels are difform; the flowers in the disk are hermaphrodite, and are composed of five heart-shaped inflexed petals, which are almost equal; the germen is situated under the flower, supporting two awl-shaped permanent styles, crowned by two obtuse segments; the germen afterward becomes an oval fruit, divided into two parts, containing two almost oval seeds, convex on one side, and plain on the other. There are five species.

One of the species of this plant, distinguished by its yellow juice, and growing near waters, is a very terrible poison. Many accounts have been given of people dying by it, but none which sets its terrible effects in so just a light, as one which happened very lately to some French prisoners with us, and which is recorded in the *Philosophical Transactions*, N^o 481.

It is extremely necessary that this dangerous plant should be well known, as it grows very plentifully with us all about the banks of the Thames; and Mr. Warton has caused a fine drawing, both of this, and of another poisonous plant, which is often confounded with the cicuta aquatica, or water hemlock of Wepfer, to be prefixed to that number of the *Transactions* where this account is given; and this seems the more necessary, as the plant seems to have been mistaken in a manner by all the world, not only by the common people, but the more verified in plants having mistaken it at times for several very different things. The same gentleman informs us, from various authors, that eight Lads in Ireland had been poisoned by it, mistaking it for the root of the water parsnip; two men died by mistaking it for the Macedonian parsley; and Wepfer, who wrote an express treatise on the poisonous nature of the water-hemlock, has confounded this plant with it, saying, that Læbel had described the water-hemlock under the name of this *anemone*, or *droppwort*; and the generally accurate Hoffman, when treating of the vegetable poisons, makes no mention of the difference between these two plants.

Neither the roots of this *anemone*, nor those of the cicuta aquatica, or water hemlock of Wepfer, have any disagreeable flavour to deter those who taste of them from eating; and they both occasion violent convulsions, and death, if not timely prevented. The method of cure seems in both the same; first by emptying the stomach and intestines as soon as possible, and then causing the patient to drink largely of oleaginous fluids; there is great difficulty, however, in getting the patient to swallow any thing, the jaws being fastened together by the

fa'm. After the stomach has been freed from this pernicious vegetable, the symptoms have generally abated by degrees, and the patient has recovered.

Therfeldt mentions this plant as growing in Cumberland, where the people call it *drad lenger*, and use it as a poultice to the galled backs of their horses. The German botanists do not mention it as growing among them, nor Haller in his *Enumeratio Stirpium Helveticæ*; whence it seems to be seldom met with, except in England, Holland, and some parts of France.

DROSERA, in *Bucina*. See *Sims-Dro*.

DROSOLITHUS, in *Natural History*, the name of a stone to which many great virtues are attributed, by the writers of the middle ages, but the accounts they have left us of it, are too imperfect to give us any just idea of what thing it was. They say it was variegated with many colours; and that when laid upon the fire it went or oozed out large drops of clear water, all over its surface.

DROVES, are persons that buy cattle in one place, and drive them for sale to another. They are to be married men, and householders, and to be licensed by statute 5 Eliz. cap. 12. And if they drive their cattle on the Lord's day, they shall forfeit 20s. by 1 Car. I. cap. 1.

DROUGHT, in the *Natural History of the Air*, is a long continuance of dry weather. Great draughts are very prejudicial to the farmer and his pasture; and such years afford but very little reward for the labour and expence of keeping it in order. The only remedies are high enclosures, and plenty of water at hand. The first of these is always in the farmer's power, and should be carefully provided by planting hedges in a proper manner, in counties most subject to suffer by this disadvantage. The other is not always so easy, but may be managed several ways, as by sinking wells; but these, when deep, are very expensive; or by bringing the water in pipes, gutters, or other conveyances; and this is easily done where there is a spring or brook in the neighbourhood higher than the lands. Pumps, wheels, and such other engines are also used in some places to bring on the water; and in others, ponds, cisterns, and receptacles, are made to take in the rains and winter floods, and retain the water till summer, when it is wanted.

The farmers of England are very deficient in this last method, which they might use to their great benefit in many places. In Spain they have no water in many parts but what they preserve in this manner. And at Amsterdam and Venice they have whole cellars made into cisterns, which receive the water that falls in rains, and preserve it all the year. Want of water for the cattle in summer in many places might be easily remedied by some care of this kind; and many thousand acres of land made useful which are now left as waste, by this means alone. The practicability of this bringing water is evinced by its being done in places where there falls much less rain annually than with us, and yet by this the inhabitants have always fresh water enough for the use of their houses, cattle, and gardens, none of which ever fail. See *CISTERN*.

DROWNING, the act of suffocating, or being suffocated, by water.

People not accustomed to diving, Dr. Halley observes, begin to drown in about half a minute's time. Drowning was anciently a kind of punishment. In the time of Louis XI. of France, the chronicle assures us, that they frequently drowned their criminals, instead of hanging them. Chron. Scand. See *Fossa* and *FORCA*. Natural historians and physicians furnish us with divers well attested instances of surprising recoveries of persons drowned; which, if naturally considered, might perhaps let a little light into the dark notions of life and death.

We shall not particularly recite the improbable stories mentioned by Pechlin, De Aer. & Alim. Def. cap. 10. of one who was under water fifteen hours, of another who was under water three whole days, and of a third who was in this state seven weeks, and recovered. *Sit pueri ipsam fidem*. But there are several unquestionable facts, though they have rarely occurred, in every country, which show the possibility of a recovery from sudden death, whether by apoplexy, convulsive fits, suffocation by noxious vapours, strangulation by the cord, or drowning. However, instances of this kind merely excited transient attention and surprise, and many persons were left for want of proper attempts for their recovery. This was particularly the case in Holland, where, from the great abundance of canals and inland seas, the inhabitants are much exposed to accidents by water; and where many persons were drowned every year for want of assistance. In 1767, a society was formed at Amsterdam, which offered premiums to those who should save the life of a citizen in danger of perishing by water; and which proposed from time to time, to publish the treatment, and method of recovery, observed in such cases. This institution was every where encouraged through the

United Provinces, by the magistrates, and by the states general, and has been attended with very considerable success; and it appears that no less than two hundred persons have been recovered from death, by this institution, in the space of about six years. In several of these cases, the recovered patients had continued upwards of an hour, without any signs of life, after they had been taken out of the water. Infligated by this example, the magistrates of health at Milan and Venice issued orders, in 1768, for the treatment of drowned persons. The city of Hamburg appointed a similar ordinance to be read in all their churches, extending their succour, not only to the drowned but to the strangled, to those suffocated by noxious vapours, and to the frozen. The first part of the Dutch Memoirs was also translated into the Russian language, by command of the emperors. In 1769, an edict was published in Germany, extending its directions and encouragement to every accident, like death, that afforded a possibility of relief. In 1771, the magistrates of the city of Paris also founded an institution in favour of the drowned; and in France they have been instrumental in saving forty-five persons out of fifty-nine, in about sixteen months. In 1773, Dr. Coogan, and Mr. afterwards Dr. Hawes, of London, proposed a plan for the introduction of a similar institution into these kingdoms. The plan was so well received and encouraged, that they were soon, viz. in 1774, enabled to form a society, since called the Humane Society, for promoting its laudable designs.

The following abstract of the plan of this society, and method of treatment recommended by it, will not, we apprehend, be unacceptable to our readers. This society has undertaken to publish, in as extensive a manner as possible, the proper methods of treating persons in the unfortunate circumstances, to which they extend their relief; to distribute a premium of two guineas among the first persons, not exceeding four in number, who attempted to recover any person, taken out of the water for dead, within thirty miles of the cities of London and Westminster, provided they have not been longer than two hours under the water, and provided the assistants persevere in the use of the means recommended for the space of two hours, whether their attempts are successful or not. These rewards are also to include every other instance of sudden death, whether by suffocation from noxious vapours, hanging, lyncopies, freezing, &c. They propose to distribute in like manner four guineas whenever the patient has been restored to life; to give to any publican, or other person, who shall admit the body into his house without delay, and furnish the necessary accommodations, the sum of one guinea, and to secure them from the charge of burial in unsuccessful cases; and to present an honorary medal to these medical gentlemen, or others, who give their assistance gratis, and who are provided with a fumigator, and other necessary always in readiness, in all those cases in which they may prove instrumental of success. The device on one side of their medal is a boy, who is represented blowing an extinguished torch, with the hope, as the legend, *Luxat flammula personam*, imports, that a little spark may still remain. The reverse exhibits a civic wreath, which was the Roman reward for saving the life of a citizen, with a blank for the name of a person to whom the medal may be given; the inscription round the wreath, *Hic pretium cito servatus tui*, expresses the merit which obtained it. The following is the method of treatment recommended by the society.

1. In removing the body to a convenient place, great care must be taken that it be not bruised, nor shaken violently, nor roughly handled, nor carried over the shoulders with the head hanging downwards, nor rolled upon the ground, or over a barrel. For experience proves, that all these methods are injurious, and often destroy the small remains of life. The unfortunate object should be cautiously conveyed by two or more persons, or in a carriage upon straw, lying as on a bed, with the head a little raised and kept in as natural and easy a position as possible.
2. The body being well dried with a cloth, should be placed in a moderate degree of heat, but not too near a large fire. The windows or door of the room should be left open, and no more persons be admitted into it than those who are absolutely necessary. As the life of the patient greatly depends upon having the benefit of a pure air, the warmth most promising of success is that of a bed or blanket, properly warmed. Bottles of hot water should be laid at the bottom of the feet, in the joints of the knees, and under the arm pits; and a warming pan moderately heated, or hot bricks wrapped in cloths, should be rubbed over the body, and particularly along the back. The natural and kindly warmth of a healthy person lying by the side of the body has been found in many cases very efficacious. The shirt or cloaths of an attendant, or the skin of a sheep fresh killed, may also

be used with advantage. Should these accidents happen in the neighbourhood of a warm bath, brew-house, baker, glass-house, filter, soap-boiler, or any fabric where warm lees, ashes, embers, grains, sand, water, &c. are easily procured, it would be of the utmost service to place the body in any of these, moderated to a degree of heat, but very little exceeding that of a healthy person.

3. The subject being placed in one or other of these advantageous circumstances as freely as possible, various stimulating methods should next be employed. The most efficacious are, to blow with force into the lungs, by applying the mouth to that of the patient, closing his nostrils with one hand, and gently expelling the air again by pressing the chest with the other, imitating the strong breathing of a healthy person. The medium of a handkerchief, or cloth, may be used, to render the operation less indelicate. If the lungs cannot be inflated in this manner it may be attempted by blowing through one of the nostrils, and at the same time keeping the other closed. Dr. Monro for this purpose recommends a wooden pipe, fitted at one end for filling the nostril, and at the other for being blown into by a person's mouth, or for receiving the pipe of a pair of bellows, to be employed for the same purpose, if necessary. Whilst one assistant is constantly employed in this operation, another should throw the smoke of tobacco up by the fundament into the bowels, by means of a pipe, or FUMIGATOR, such as are used in administering clysters; or by a pair of bellows till the other instrument can be procured. A third attendant should, in the mean time, rub the belly, chest, back, and arms, with a coarse cloth, or flannel, dipped in brandy, rum, or gin, or with dry salt, so as not to rub off the skin; spirits of hartshorn, volatile salts, or any other stimulating substance, must also be applied to the nostrils, and rubbed upon the temples very frequently. Electrical shocks, made to pass in different directions through the body and particularly through the heart and lungs, have been recommended as very powerful stimuli; and from the trials that have already been made, promise considerable success. The body should at intervals be shaken aloft, and varied in its position.

4. If there be any signs of returning life, such as sighing, gasping, twitching, or any convulsive motions, beating of the heart, the return of the natural colour and warmth, opening a vein in the arm or neck may prove beneficial; but the quantity of blood taken away should not be large; nor should an artery ever be opened, as profuse bleeding has appeared prejudicial, and even destructive to the small remains of life. The throat should be tickled with a feather, in order to excite a propensity to vomit; and the nostrils also with a feather, snuff, or any other stimulant, so as to provoke sneezings. A tea-spoon full of warm water may be occasionally administered, in order to learn whether the power of swallowing be returned; and if it be, a table-spoon full of warm wine, or brandy and water, may be given with advantage; but not before, as the liquor might get into the lungs, before the power of swallowing returns. The other methods should be continued with vigour, until the patient be gradually restored.

When the patient has been but a short time senseless, blowing into the lungs or bowels has been, in some cases, found sufficient; yet a speedy recovery is not to be expected in general. On the contrary, the above methods are to be continued with spirit for two hours, or upwards, although there should not be the least symptoms of returning life. The same means of restoration are applicable to the various other cases of sudden death, recited in the beginning of this article.

When these measures prove unsuccessful, the surgeon's last resource is BRONCHOTOMY, or opening the *arteria trachea*; for perhaps the air entering freely into the lungs, through the aperture made in the canal, through which they received it in their natural state, will restore the play of the lungs, and all the motions of the breast.

Mr. Hunter, F. R. S. has, at the request of a member of the Humane Society, published proposals for recovering persons apparently drowned. In the case of apparent death by *drowning*, he considers that a suspension of the actions of life has taken place, owing to the loss of respiration, and the immediate effects which this has on the vital motions of the animal: at least, he says, this privation of breathing appears to be the first cause of the heart's motion ceasing; therefore, most probably, the restoration of breathing is all that is necessary to restore the heart's motion. The loss of life in *drowned* people has been accounted for, by supposing that the blood, disorganised by want of the action of the air in respiration, is sent, in that vitiated state, to the brain, and other vital parts; by which means the nerves lose their effect upon the heart, and the heart in consequence its motion. But

Mr. Hunter concludes from experiments on a dog, in which a large column of bad blood, viz. all that was contained in the heart and pulmonary veins, was pushed forward, without producing any ill effect, and also from the recovery of *drowned* persons, and full-born children, that the heart's motion must depend immediately on the application of air to the lungs, and not on the effects which air has on the blood, and which that blood has on the vital parts. Therefore blowing air into the lungs, soon after the immersion, may be sufficient to effect a recovery; and the *dephlegmated* AIR of Dr. Priestley may prove more efficacious than common air. But if a considerable time, as an hour has been lost, it may be necessary to apply stimulating medicines, as the vapour of volatile alicia, mixed with the air; and these are best thrown in by the nostrils, as applications of this kind to the olfactory nerves rouse the living principle, and put the muscles of respiration into action, while some applications to the mouth rather depress than rouse, by producing sickness. The larynx should be at the same time pressed against the oesophagus and spine, which will prevent the stomach and intestines from being too much distended by the air; however, the trachea, and the aperture into the larynx, should be both left perfectly free. Heat is also congenial with the living principle, which by increasing the necessity of action, increases action; and to a due proportion of heat the living principle owes its vigour. Bed-cloths properly heated should, therefore, be gently laid over the patient, and the steam of volatile alicia, or of warm balsams, and essential oils may be thrown in, so as to come in contact with many parts of his body. The same steam may also be conveyed into the stomach by means of a hollow bougie, and a syringe; together with the spirits of hartshorn, pepper-mint water, juice of borle-raddish, and also balsams and turpentine, in such small quantities, as not to produce sickness. These may also be thrown up by the anus. When the heart begins to move, Mr. Hunter advises to lessen the application of air to the lungs, he absolutely forbids bleeding, because it weakens the animal principle, or that principle which preserves the body from dissolution, and is the cause of all its actions, and which Mr. Hunter supposes to be inherent in the blood, and consequently lessens both the power and disposition to action. Nothing should be administered that ordinarily produces a nausea or vomiting, or by the anus, that has a tendency to produce an evacuation that way; because every such evacuation tends to lessen the animal powers. On this account he does not particularly recommend the fumes of tobacco, because they always produce sickness or purging, according to the mode of their application. He recommends the following apparatus, with a view to the purposes of this society. First, a pair of bellows; so contrived with two separate cavities, that by opening them, when applied to the nostrils or mouth of a patient, one cavity may be filled with the common air, and the other with air sucked out from the lungs; and by shutting them again, the common air may be thrown into the lungs, and that sucked out of the lungs discharged into the room. The pipe of these should be flexible, in length a foot or a foot and a half, and at least three eighths of an inch in width; by this the artificial breathing may be continued, while the other operations, the application of the stimuli to the stomach excepted, are going on, which could not conveniently be the case, if the muzzle of the bellows were introduced into the nose. The end next the nose should be double, and applied to both nostrils. Secondly, a syringe with a hollow bougie, or flexible catheter, of sufficient length to go into the stomach, and to convey any stimulating matter into it, without affecting the lungs. Thirdly, a pair of small bellows, such as are commonly used in throwing fumes of tobacco up the anus. Phil. Trans. vol. lxxi. part. ii. p. 412. 425.

The Humane Society, since its first establishment, to the beginning of the year 1779, has been instrumental in recovering two hundred and eighty-seven persons out of the number of cases, to which their attempts have been applied. See Reports of the Society for the Recovery of Persons apparently *drowned*.

Societies of a similar nature have been lately formed at Norwich, Bristol, Liverpool, Colchester, and Hull; and likewise at Cork, in Ireland. The board of police in Scotland has also interested itself in favour of the same benevolent design.

DRUG, in Commerce, a general name for all spices and other commodities, brought from distant countries, and used in the business of medicine, and the medicinal arts. The drugs used in medicine are very numerous, and the greatest part of the commerce of our Western Islands, and of their grow in England, France, &c. but the greatest part are brought from the Levant, and the East Indies.

A list of all of them would be endless. Some of the principal are aloes, ambergris, amber, asa-fetida, antimony, bezoar, borax, benjamin, camphor, cantharides, cardamom, cassia, callosum, coquintida, civet, coral, cubebæ, coffee, cocoa, gum animæ, armoniac, adraganth, elemi, gamboge, labdanum, opopanax, sagapænum, sandarac, lactæ, jalap, manna, mastic, myrrh, musk, opium, pearls, quinquina, hellbore, galanga, zedoary, rhubarb, farsaparilla, floræ, galbanum, sanguis draconis, lenna, spermaceti, spica nardi, scammony, sal ammoniac, tamarind, tea, turpentine, turbit, tutia, &c.

The natural history, &c. whereof, see under their respective articles. **ALOEÆ, AMBERGRIS, &c.**
The drugs used by dyers are of two kinds: the *colouring*, which give a dye or colour; and *non-colouring*, which only dispose the stuffs to take the colours the better, or to render the colours more shining. Of the first kind are paltels, woad, indigo, kermes, cochineal, madder, turmeric, &c. Of the second kind are, alum, tartar, arsenic, real-gal, salt-petre, common salt, sal gemme, sal ammoniac, crystals of tartar, agaric, spirit of wine, urine, pewter, iron, bran, starch, lime, &c.

There is a third sort of *drugs*, which answer both intentions; as the root, bark, and leaf, of the walnut-tree, galls, copperas, &c.

DRUGGET, in Commerce, a sort of stuff, very thin, and narrow, sometimes all wool, and sometimes half wool, and half thread; having sometimes the whale, but more usually without.

Those without the whale in the plain *druggets* are woven, on a loom with two treddles, after the same manner as linen, cambiet, &c. Those with the whale, or the corded *druggets*, are wrought on a loom with four treddles. Those are called threaded *druggets*, that have the wool of wool, and the warp of thread. M. Savery invented a kind of gold and silver *drugget*; the warp being partly gold and silver thread, and the wool linen.

DRUIDS, or DAVIDES, or DAVIDA, the priests or ministers of religion, among the ancient Celts, or Gauls, Britons, and Germans.

Some authors derive the word from the Hebrew *דָּרִישׁ*, *derashim*, or *drashim*, which they translate, *contemplantur*. Picard, Celsopæd. lib. ii. p. 58, believes the *Druids* to have been thus called from *Drui*, or *Dryus*, their leader, the fourth or fifth king of the Gauls, and father of Saron, or Naumes. Pliny, Salmastus, Vigenere, &c. derive the name from *Drui*, oak; on account of their inhabiting, or at least frequenting, and teaching in forests; or perhaps, because, as Pliny says, they never sacrificed but under the oak. But it is hard to imagine, how the *Druids* should come to speak Greek. Menage derives the word from the old British *drui*, *druid*, *magician*. Borel, from the Saxon *dry*, *magician*; or rather from the old British *drui*, or *derui*, oak; whence he takes *Drui* to be derived, which is the most probable supposition. Gorop. Becanus, lib. i. takes *drui* to be an old Celtic, and German word, formed from *drui*, or *druid*, a doctor of the truth and the faith; which etymology Vossius acquiesces in.

The *Druids* were the first, and most distinguished order among the Gauls and Britons; they were chosen out of the best families; and the honours of their birth, joined with those of their function, procured them the highest veneration among the people. They were versed in astrology, geometry, natural philosophy, politics, and geography; and had the administration of all sacred things; they were the interpreters of religion, and the judges of all affairs, indifferently. Whoever refused obedience to them, was declared impious and accursed.

We know but little as to their peculiar doctrines; only that they believed the immortality of the soul; and, as is generally also supposed, the metempsychosis; though a late author makes it appear highly probable they did not believe this last, at least not in the sense of the Pythagoreans.

The chief settlement of the *Druids* in Britain was in the Isle of Anglesey, the ancient *Alana*, which they might chuse for this purpose, as it was well stored with spacious groves of their favourite oak.

They were divided into several classes, or branches; viz. the *vacerri*, *barai*, *rubegi*, *semnotii*, or *semnotii*, and *farinidei*. The *vacerri* are held to have been the priests; the *barai*, the poets; the *rubegi*, the augurs; and the *farinidei*, the civil judges, and instructors of youth. As to the *semnotii*, who are said to have been immediately devoted to the service of religion, it is probable, they were the same with the *vacerri*.

Strabo, however, lib. iv. p. 197, and Picard after him, in his Chronologia, do not comprehend all these different orders under the denomination of *Druids*, as species under their genus, or parts under the whole; but make them quite different conditions, or orders.

Strabo, in effect, only distinguishes three kinds; *barai*, *vacerri*, and *Druidi*. The *barai* were the poets; the *vacerri*, apparently the same with the *vacerri*, were the priests and naturalists; and the *Druidi*, beside the study of nature, applied themselves likewise to morality.

Diogenes Laertius assures us, in his Prologue, that the *Druidi* were the same, among the ancient Britons, with the sophi, or philosophers, among the Greeks; the magi, among the Persians; the gymnosophists, among the Indians; and the Chaldeans, among the Assyrians.

The *Druidi* had one chief, or *arch-druid*, in every nation, who acted as high-priest, or *pontifex maximus*. He had absolute authority over the rest; and commanded, decreed, punished, &c. at pleasure. At his death he was succeeded by the most considerable among his survivors; and if there were several pretenders, the matter was ended by an election, or else put to the decision of arms.

The *Druidi*, we have observed, were in the highest esteem. They presided at sacrifices, and other ceremonies; and had the direction of every thing relating to religion. The British and Gaulish youth flocked to them in crowds, to be instructed by them. The children of the nobility, Mela tells us, they retired with into caves, or the most desolate parts of forests, and kept them there, sometimes for twenty years, under their discipline.

Beside the immortality and metempsychosis, they were here instructed in the motion of the heavens, and the course of the stars; the magnitude of the heavens and the earth; the nature of things; the power and wisdom of the gods, &c. They preserved the memory and actions of great men in their verses, which they never allowed to be wrote down, but made their pupils get them by heart. In their common course of learning, they are said to have taught them twenty-four thousand such verses.

They held the plant mistletoe in singular veneration. Pliny relates the ceremony wherewith they gathered it every year, lib. xvi. cap. 44. They placed great confidence also in serpent's eggs, gathered after a peculiar manner, and under a certain disposition of the moon, described by Pliny; and imagined them effectual means for the gaining of law-suits, and procuring the good graces of princes. And hence the same author concludes it is, that the caduceus, or rod encompassed with two serpents interwoven, has been assumed as a symbol of peace. Suetonius, in his life of Claudius, assures us, they sacrificed men; and Mercury is said to be the god to whom they offered their victims. Dios. Siculus, lib. vi. observes, it was only upon extraordinary occasions they made such offerings; as, to consult what measures to take, to learn what should befall them, &c. by the fall of the victim, the tearing of his members, and the manner of his blood gushing out. Claudius condemned the custom; and Liberius, and Claudius, punished and abolished it. See Cæsar, lib. vi. cap. 13, and Mela, lib. iii. cap. 2.

We learn from Cæsar, that the *Druidi* were the judges and arbiters of all differences and disputes, both public and private; they took cognizance of murders, inheritances, boundaries, and limits, and decreed rewards and punishments. Such as disobeyed their decisions, they excommunicated, which was their principal punishment, the criminal being hereby excluded from all public assemblies, and avoided by all the world; so that no body durst speak to him for fear of being polluted. Strabo observes, they had sometimes interest and authority enough to stop armies upon the point of engaging, and accommodate their differences.

They held an assembly, every year, at a certain season, about the middle of the country; and there, in a place consecrated for the purpose they kept their assizes, and terminated the differences of the people, who flocked thither from all parts.

Cæsar, who had seen some of the *Druidi* in Britain, was of opinion, they had come thence into Gaul: divers among the moderns take this for a mistake, and believe the very contrary. In effect, it appears pretty probable, that the ancient Britons were originally Gauls; that some of the Celts, or Belgæ, Gaulish nations, were the first that entered our island, and peopled it; and that the *Druidi* went along with them.

Hornius, in his History of Philosophy, lib. ii. cap. 12, believes all the learning and philosophy of the *Druidi* to have been derived from the Assyrian magi; who are still called in Germany, *truten*, or *trutter*; and that, as magus has lost its ancient signification, which was honourable, and now signifies a magician, or forcerer; so *Druid*, which had the same sense, has likewise degenerated, and now signifies no other than a person who has commerce with the devil, or is addicted to magic. And,

accordingly, in Friesland, where there anciently were *Druids*, witches are now called *Druids*. Gale, Dickenson, and some others, vainly contend, that the *Druids* borrowed all their philosophy, as well as religion, from the Jews.

There were also women who bore the appellation *Druides*, or *Druides*, among the Gauls, &c. The authors of the *Historia Augusta*, particularly Lampadius, and Vopiscus, make mention of these.

Salmassius, in his notes on Lampadius, is a little in doubt who these women were; but he gives into the most easy and plausible opinion, that they were either the wives or the children of the *Druids*.

DRUM, *Tympanum*, a military musical instrument, said by Le Clerc to be an oriental invention, and brought by the Arabians, and perhaps the Moors, into Spain; of use, both among the foot and dragoons, serving to call the soldiers together, and to direct their march, attack, retreat, &c.

The body of the *drum* is made of very thin oak, which is bent into a cylinder, and covered at each end with parchment, which is strained, or braced more or less, according to the height or depth of the sound required, by small cords and sliding leathers; and is then struck with sticks. The depth of the *drum* is equal to its breadth, which does not exceed two feet and a half, because no skin can be had to cover bigger. Every troop of dragoons, and every company of foot or artillery, has two or more *drums*, according to the number of men. There are also *drums* whose body is of brass, which are of use principally among the horse. See **KETTLEDRUMS**.

DRUM, or **DRUMMER**, also denotes a soldier appointed to beat the *drum*. When a battalion is drawn up, the *drum* are on the flanks; and when it marches by divisions, they march between them.

There are divers beats of the *drum*; as the *general march*, *double march*, *assembly*, *charge*, *retreat*, *alarm*, *chamade*, *retreat*, *recall*, *tattoo*, &c. See **ASSEMBLY**, **CHAMADE**, &c.

DRUM-MAJOR, is that person in a regiment who beats the beat *drum*, commands the others, and teaches them their duty. Every regiment has a *drum-major*.

DRUM, in *anatomy*, or *Ear-DRUM*, denotes a cavity in the inner ear; thus called from the resemblance it bears to the figure of a war-drum. See **EAR**.

Its outer extreme is covered with a membrane, by anatomists called *tympanum*, *drum*; but, more properly, *membrana tympani*.

The office of this *drum*, or *membrana tympani*, has been greatly controverted by anatomists. The account best warranted is, that being a medium for the conveyance of the sound of the auditory nerve, by its different degrees of tension, it serves to modify the sound, and propagate it to the nerve well proportioned, and commensurate thereto. See **HEARING** and **SOUND**.

DRUM, *String of the*. See **CHORDA TYMPANI**, and **EAR**.

DRUM *head of a captain*. See **CAPTAIN**.

DRUM, in *Architecture*. See **TAMBOUR**.

DRUM is used to signify a kind of fish in Virginia. The oil of this fish is said to cure pains in the limbs, frequent in that country. See **PHIL. Trans. N° 454. § 1.**

DRUM, *Mare*. See **BITTERN**.

DRUNGUS, *Δρυγος*, a body, or company of forces; thus called in the later times of the Roman empire.

The name *drungus*, as appears from Vegetius, lib. iii. cap. 16, was at first only applied to foreign, and even enemies troops; but, under the Eastern empire, it came in use for the troops of the empire itself; where it amounted, pretty nearly, to what we call a regiment, or brigade.

The same author notes, that *Δρυγος*, among the modern Greeks, signifies a *staff*, or *rod*, the badge of a dignity, or office, as *agla* among the Turks; and he thinks, that the name may be formed from the Latin *drumbar*. But it appears from Vegetius, that *drungus* is a barbarous, not a Latin word. Spelman takes it for Saxon; because, at this day, *throng*, in English, signifies a multitude. Salmassius derives it from *Δρυγος*, *beak*, on account of the *drungus*'s being disposed beak-wise, or terminating in a point.

Leunclavius observes, that the *drungus* was not less than one thousand men, nor more than four thousand.

DRUNKENNESS, *Ebrietas*, physically considered, consists in a preternatural compression of the brain, and a discomposure of its fibres; occasioned by the fumes, or spirituous parts of liquors. It is accounted for thus: an immoderate quantity of wine taken into the stomach, is there heated, and undergoes a kind of effervescence; which arises the more readily, as the liquor abounds the more in sulphur. By this action it becomes attenuated and rarefied; so that the grosser parts being left behind,

its finer parts are fitted to penetrate, and shoot through the veins to the brain; or are conveyed through the veins to the heart; whence, after a farther heat and rarefaction, they are sent through the carotid arteries, &c. to the brain: hence necessarily arises a repletion of the meninges of the brain, and a compression of the fibres of the brain itself, from the fresh flock of rarefied sulphur continually ascending into them: hence, also, arise obstruction of the pores or passages of the brain, a frequent and disorderly pulsation of the fibres, and the other symptoms of this disordered state.

Hence it is, that all liquors will not give *drunkenness*; but only such as, by their sulphur, or spirit, are disposed for an effervescence in the stomach and heart, to diffuse their subtle attenuated parts plentifully to the brain.

It is a popular mistake, that the only remedy for gluttony, is *drunkenness*, or that the cure of a surfeit of meat, is a surfeit of wine; than which nothing can be more contrary to nature. Cheyne.

The ancient Lacedæmonians used to make their slaves frequently *drunk*, to give their children an aversion and horror for this vice. The Indians hold *drunkenness* a species of madness; and, in their language, the same term *ranjam*, that signifies *drunkard*, signifies also a *phrenetic*.

Drunkenness is punishable by the laws of England. The penalty is five shillings fine, or the stocks in case of non-payment. For a second offence the guilty person may be bound to his good behaviour. And an alehouse-keeper convicted of the same offence, shall be disabled to keep any such alehouse for three years. All flag officers and persons belonging to his majesty's ships of war, being guilty of *drunkenness*, are liable to such punishment, as a court martial shall think fit to impose. See **stat. 4 Jac. I. cap. 5. 21 Jac. I. c. 7. 22 Geo. II. c. 33.** Hobbes makes voluntary *drunkenness* a breach of the law of nature, which directs us to preserve the use of our reason. The law of England also does not allow it to be an excuse in any case whatsoever.

DRUPE, among *Botanists*, a species of pericarpium, consisting of a soft, fleshy, and succulent pulp, without valves, in the centre of which there is a nucleus. See **PERICARPIMUM**.

DRUSA, in *Natural History*, a name given by some of the Saxon miners to the common pyrites, and by others to some peculiar kinds of it. But in general it is understood to signify both the pyrites and the marcasite.

DRUSES, or **DRUSIANS**, in *Ecclesiastical History*, a people of Palestine, inhabiting the environs of mount Lebanon, who call themselves Christians, and occasionally profess themselves Mahometans; but all their Christianity consists in speaking with respect of Jesus Christ and the Virgin Mary. They are somewhat jealous of their wives, who only among them know how to read or write. They consider men as defined by their strength, courage, and understanding, to more useful and exalted pursuits than tracing characters upon paper; and are not able to conceive how a man who is capable of bearing arms, can amuse himself with turning over the leaves of a book. They carry on a trade in wine, silk, corn, and saltpetre. They have had several disputes with the Turks, who govern them by emirs, that have several times been strangled by them.

The *Druses* are probably the remains of the Christian armies in the holy war; and they themselves now say, that they are descended from the English; though others say, they are descended from the Franks, whom Godfrey of Bulloign brought with him to the holy war. Pococke's *Des. of the East*, vol. ii. book i. chap. 1.

DRY. A dry air, *cæteri paribus*, lessens the weight of the human body, and the contrary quality increases it. See **MOISTURE**.

DRY Balbs, *Castelli*, *Duck*. See the substantives.

DRY Exchange, *Combinum fixum*, a soft appellative, anciently used to disguise usury under, intimating something to pass on both sides; whereas, in truth, nothing passed but on one; in which respect it might be called *dry*. See **INTEREST** and **USURY**.

Combinum fixum, says Lud. Lopez, de Contractu & Negot. *est combinum non habens existentiam combis, sed appetitum, ad effectum arboris exsiccatæ, &c.*

DRY Fish, *Fruiti*, *Moss*, *Alcajures*. See the substantives.

DRY Meat, in the *Almagest*, is used for corn and hay. After taking the horse from grails, or houlding him, it is frequently put to dry meat.

DRY Moss, *Kent*, *Sitras*, *Satures*, *Spartes*. See the substantives.

DRYADES, **DRYADES**, in the *Heavenly Geography*, the name of the woods; a sort of imaginary beings, which the ancients believed to inhabit the woods, and to endeavour to hide themselves under the bark of the oak, called by the Greeks *Δρυς*.

The *dryades* differed from the *hamadryades*, in that these latter were attached to some particular tree, with which they were born, and with which they died; whereas the *dryades* were the goddesses of the trees and woods in general, and lived at large, in the middle thereof. For, though *dryas* properly signifies an oak, it was also used for tree in general.

We likewise find mention made, in divers authors, of a kind of prophetic, or witches, among the Gauls, called *dryades*, or rather *druides*. See DRUIDS.

DRYERS, in *Painting*, are substances to be called from their use in remedying the fault of oils, which dry too slowly. See Drying Oil.

DRYAS, in *Botany*, the name of a genus of plants of the *isofandra polygama* class; called also by some *dryolae*, and by Tournefort and others made a species of the *coriophylla*. The characters are these: the perianthium is composed of one leaf divided into eight straight, obtuse, equal segments, somewhat shorter than the petals of the flower; the flower consists of eight oblong, expanded, emarginated petals, inserted into the cup; the stamina are numerous, very short capillary filaments inserted into the cup; the anthers are simple and small; the germina are numerous, small, and set close together; the styles are capillary, and are inserted into the sides of the germina, and the stigmas are simple; there is no fruit, but the seeds stand naked together, and are numerous, and of a roundish compressed figure, and sustain a number of hairy styles. There are two species.

DRYINUS, *Ophioglossa*, a species of serpent, so called from its being usually found about hollow oaks. Bellonius, who has mentioned it, says, that scarce any serpent grows to a larger size, or makes a more terrible biting. Authors in general seem however to little agreed about its description that it is not easy to ascertain the name to any peculiar species of snake.

DRYITES *lepis*, in *Natural History*, a name given by authors to a substance but ill deserving the name of a stone; it being only foliaceous wood found in detached masses. There is much of this foliaceous wood found in Italy, in the banks and on the shores of rivers. We know also by what we see of the foliaceous wood of England, that it may be found in all degrees of petrification, from that of almost unaltered wood to absolute stone or mineral matter, with only the superficial grain of wood. See Pflaster Wood.

DRYOPHIA, *Asperula*, in *Antiquity*, an anniversary day observed in memory of Dryops, one of Apollo's sons.

DRYPIS, in *Botany*, a genus of plants of the *pentandria trigynia* class: the calyx is cut into five segments: the petals are five; and the fruit is a covered capsule, containing a single seed. There is one species.

DS JERENANG, a name by which some authors have called a species of palm-tree, from the fruit of which is procured dragon's blood. Kämpfer, Amoen. Exot. p. 552.

DUALISM, or DITHIRISM, an opinion which supposes two principals, two gods, or two independent uncreated beings, of which one is the first cause of good, the other of evil. See MANICHEISM.

DUBBING *a cock*, cutting off his comb and wattles.

DUBIOUS *Acids*. See ACIDS.

DUBITATIVE *Conjunctions*. See CONJUNCTION.

DUCAL. The letters patent granted by the senate of Venice, are called *ducals*: so also are the letters written, in the name of the senate, to foreign princes.

The denomination of *dual* is derived hence; that, at the beginning of such patents, the name of the duke, or doge, is wrote in capitals, thus, *N—m Dei Gratia Dux Venetiarum*, &c. The date of *duals* is usually in Latin, but the body is in Italian. A courier was dispatched with a *dual* to the emperor returning him thanks for renewing the treaty of alliance (in 1716) against the Turks, with the republic of Venice.

DUCAT, a foreign coin, either of gold or silver, struck in the dominions of a duke: being about the same value with a Spanish piece of eight, or a French crown, or four shillings and sixpence sterling, when of silver; and twice as much when of gold. See COIN.

The origin of *ducats* is referred to one Longinus, governor of Italy; who, revolting against the emperor Justin the Younger, made himself duke of Ravenna, and called himself *Exarcha*, i. e. without lord or ruler; and, to show his independence, struck pieces of money of very pure gold, in his own name, and with his own flag, which were called *ducats*, *ducats*; as Procopius relates the story.

After him, the first who struck *ducats* were the Venetians, who called them also *Zucconi*, or *seguini*, from *Zucca*, the place where they first were struck. This was about the year 1280, in the time of John Dandolo; but we have pretty good evidence that Roger king of

Sicily had coined *ducats* as early as 1240. And Dugange scruples not to affirm, that the first *ducats* were struck in the duchy of Apulia, in Calabria. The chief gold *ducats* now current, are the single and double *ducats* of Venice, Florence, Genoa, Germany, Hungary, Poland, Sweden, Denmark, Flanders, Holland, and Zurich. The heaviest of them weighs five pennyweights seventeen grains, and the lightest five pennyweights ten grains; which is to be understood of the double *ducats*, and of the single in proportion.

The Spaniards have no *ducats* of gold; but, in lieu thereof, they make use of the silver ones; which with them is no real species, but only a money of account, like our pounds. It is equivalent to eleven *reals*. See REAL. The silver *ducats* of Florence serve there for crowns.

DUCATOON, a silver coin, struck chiefly in Italy; particularly at Milan, Venice, Florence, Genoa, Lucca, Mantua, and Parma: though there are also Dutch and Flemish *ducatoons*.

They are all nearly on the same footing; and, being a little both finer and heavier than the piece of eight, are valued at two pence or three pence more, viz. at about four shillings and eight pence sterling. There is also a gold *ducatoon*, struck and current chiefly in Holland: it is equivalent to twenty florins, on the footing of one shilling and eleven pence halfpenny the florin.

DUCENARIUS, in *Antiquity*, an officer in the Roman army, who had the command of two thousand men.

The emperors had also *ducenarii* among their procurators, or intendants, called *procuratores ducenarii*. Some say, that these were such whole salary was two hundred sesterces; as in the games of the circus, horses hired for two hundred sesterces, were called *ducenarii*. Others hold, that *ducenarii* were those who levied the two hundredth penny, the officers appointed to inspect the raising of that tribute. In the inscription at Palmyra, the word *ducenarius*, in Greek *δουκέναιος*, occurs very often.

DUCENTESIMA, in *Antiquity*, a tax of the two hundredth penny, exacted by the Roman emperors.

DUCES *teum*, a writ commanding one to appear at a day in chancery, and to bring with him some evidences, or other things, which the court would view.

DUCES *teum* *facti languida*, a writ directed to a sheriff, who, having in his custody a prisoner, in a personal action, returns, upon a *habeas corpus*, that he is *alio languida*, that, without danger of death, he cannot have his body before the justices.

DUCK, *Anas*, in *Ornithology*, the name of a very large genus of birds, of the order of *anseris*; the characters of which are these: the beak is shorter in proportion than that of the goose, strong, flat or depressed, and commonly furnished at the end with a nail, and the edges divided into sharp lamellæ; and the feet proportionally larger, with the middle toe the longest: the legs are shorter, and are placed farther backward; and the back is flatter, and the body more compressed; the nostrils are small and oval; and the tongue broad, with the edges near the base fringed. Some of these love the fresh waters, others are found only at sea, and of both there are very numerous species. See ANAS.

This fowl is furnished with a peculiar structure of vessels about the heart, which enables it to live without respiration a considerable time under water, as is necessary for it in diving. This made Mr. Boyle think it a more proper object for experiments by the air-pump, than any of the other birds. A full-grown duck being put into the receiver of the air-pump, of which he filled one third part, and the air exhausted, the creature seemed to bear it better, for the first moments, than a hen or other such fowl; but after about a minute the pale great signs of discomposure, and in less than two minutes her head fell down, and she appeared dying, till revived by letting in the air. Thus whatever facility of diving, this and other water-fowl may have, it does not appear, that they can subsist without air for respiration, any longer than other animals. A young callow duck was afterwards tried in the same manner, and with the same success, being reduced very near death in less than two minutes. But it is observable, that both birds swelled extremely on the pumping out of the air, so as to appear much larger to the spectators, especially about the crop. It not being intended that any water-fowl should live in an exceedingly rarefied air, but only be able to continue on occasion some time under water, nature, though she has provided them with the means of this, has done nothing for them in regard to the other.

The strongest instance of this creature's being calculated to live any where, we have in the accounts of the blind ducks of the Zirczhoiter lake in Carniola. It is now well known, that this lake communicates with another lake

lake under ground in the mountain Savornick, and fills or empties itself according to the fullness or emptiness of that lake; the waters of the upper lake running off at the time of its emptying by large holes in the bottom, and that in vast quantities, the ducks which are very plentiful in the water, are often carried down with it, and forced into the subterraneous lake the waters retire to. In this unnatural habitation, many of them doubtless perish, but some remain alive; these become blind and lose all their feathers, and in the next filling of the lake, both they and vast numbers of fish are thrown up with the water. They are fat at this time but make a strange appearance in their naked state, and are easily caught, for want of sight to avoid the danger. In about a fortnight they recover their sight and their feathers, and are then of the size of a common wild duck, but of a black colour, having a white spot upon their forehead. When opened on being taken at their first coming up in their blind state, their stomachs are found full of small fishes, and somewhat resembling weeds. It seems from this that they cannot be absolutely blind, but that the degree of light to which they seem accustomed in their dark habitation, had formed their eyes to see by that small quantity, to well as to get their food by it; and their blindness on coming into broad day-light again, is no other than that of a man who has been long in the dark, on having in an instant a large blaze of candles set just under his eyes. The eye in neither case can bear the sudden change, and must be habituated to it, before it can see objects by it. These blind ducks are not only cast up in this lake, but after great rains they are frequently thrown up at a hole in the mountain Storöf, near the town of Læs. The water gushing out at this hole with great force on these occasions, brings away with it these blind and bald ducks; and their frequency on these occasions in these places, makes them be esteemed no rarity; but the common people understand that there are under ground lakes, which they inhabit, and out of which they are thus thrown. Phil. Trans. N^o 191.

There are two sorts of ducks common with us, the tame, and the wild; the *anas lagotis* of Linnaeus, and *aesoptica* of other authors. The mallard of this species has its bill of a yellowish green; the head and neck are of a deep and shining green; more than half round the lower part of the neck is an incomplete circle of white; the upper part of the breast is of a purplish red, and the beginning of the back of the same colour; the breast and belly of a pale grey, marked with transverse speckled lines of a dusky hue. The scapulars are white, barred with brown; the spot on the wing is of a rich purple; the tail consists of twenty-four feathers, the four middle ones of which are black and strongly curled upwards, which distinguishes the male of this species from all others; but the females have not this mark. Their plumage is of a pale reddish brown, spotted with black; the legs are of a buff colour. The common tame species take their origin from these. The drakes, however, they vary in colour, always retain the curled feathers of the tail; and both sexes the form of the bill of the wild kind. Pennant.

The first sort is very beneficial to the husbandman, and at the same time requires no charge to keep, as living on loft corn, worms and snails, &c. Indeed once a year, this fowl is a great layer of eggs; and when the firs, must be carefully fed with barley or other grain. As to the ducklings, they are fed in the same manner as goslings and may be fattened in three weeks time with any kind of pulse or grain, and plenty of water.

For preserving wild ducks, a place with a pond in it, must be walled in, and covered with a strong net; the pond is to be set with tufts of osiers, and have many secret holes and creeks; whereby they will be induced to feed freely, though confined. Teal, widgeons, sheldrakes, and green plovers, may also be ordered in the same manner. See Duck.

Of exotics or foreign ducks, authors describe many species; as,

Duck, the Black, or *Volva*, *Ans nigra*, or *fusca*. The male of this species is larger than the tame duck. The bill is broad and short, yellow on the sides, black in the middle, and the hook red; the head and part of the neck is black tinged with green; behind each ear is a white spot; and in each wing is a white feather; all the rest of the plumage is of a fine black, and soft as velvet; the legs and feet are red; the webs black. The female is entirely of a deep brown colour, the marks behind each ear and on the wings excepted; the bill wants the protuberance to the base which Linnaeus gives to the male. This species is common on the coast of Norway, but seldom appears with us except in hard winters. Ray and Pennant.

Duck, *Bracon*, is about the size of a goose. Its back, legs and feet are brown, and its body wholly black, with a green gloss, except the upper part of the wing, which is white. It has a crest composed of black feathers on its head, and a large red fleshy tubercle over the origin of the bill, and a naked red membrane round its eyes. It flies to the top of the highest trees, and is a very fleshy and delicately-tasted bird. Margraave.

Duck, *St Cuthbert's*, *Ans mollissima* of Linnaeus, and *Eider* of Wormius, is a species of duck found in the Western isles of Scotland, and in the Farn isles, but in greater numbers, in Norway, Iceland, and Greenland, from which a great quantity of soft down, called *eider* or *edder*, produced from the breast of the bird in breeding season, is annually imported. It is much valued for stuffing beds, coverlets, &c. The male and female differ very much in this species; the male very much resembles the common duck, but is about twice its size; its bill is black; the feathers of the forehead and cheeks advance far into the face, so as to form two very sharp angles; the forehead is of a full velvet black; from the bill to the hind part of the head is a broad black bar, passing across the eyes on each side. On the hind part of the neck, just beneath the ends of these bars is a broad pea-green mark, that appears like a stain; the crown of the head, the cheeks, the neck, back, scapulars and coverts of the wings are white; the lower part of the breast, the belly, tail, and quill-feathers, are black, and the legs are green. The female is a dusky brown, spotted with black. This species forms its nest in the holes of rocks, and among the stones on the sea-shore, and lays a number of eggs, which are of a pale olive colour, large, glossy, and smooth, and well tailed. Ray and Pennant.

Duck, *Dusky*. See Duck.

Duck, *The Fly Catching*, *Ans Moscatio*, is a name given to a kind of duck from its catching flies which fly about the waters. This is described as a distinct species by Mr. Ray, supposes it to be the same with our wild duck; Linnaeus makes it the *Ans Cypripata*, or *flavipes*.

Duck, *Ans Strepera*, is a species of duck which frequents fresh water, usually called the gadwall and gray. It is about the size of the widgeon. The bill is black and flat; the head and upper part of the neck are of a reddish brown, spotted with black; the lower part, the breast, the upper part of the back, and the scapulars, are beautifully marked with black and white lines; the belly is of a dusky white; the rump above and below is black; the tail ash-coloured, edged with white; the coverts on the ridge of the wing are of a pale reddish brown; those beneath are of a purplish red, the lowest of a deep black; the greater quill-feathers are dusky; the inner web of three of the lesser quill-feathers is white, which forms a conspicuous spot; the legs are orange-coloured. The breast of the female is of a reddish brown, spotted with black; the back of the same colour; and though it has the same marks on the wings, they are much less bright than those of the male. Ray and Pennant.

Duck, *Ans Clapqua*, or *Platyrhynchus*, a species of duck commonly called golden-eye, found about the sea-coasts, and frequently fresh waters. Its body is short and thick; its head large, of a deep black, glossed with green, and its neck short; its back is short and broad at the base, and black; at each angle of the back there is a large white spot, whence the Italians call this bird *quatt'occhi*, or *four-eyes*; the *irides* are of a bright yellow; the neck, shoulders, breast, and belly are white, and the back black; the wings are black and white, and the tail is wholly black; the legs are very short, the feet broad, and both of an orange-colour; the hinder toe is small, but is edged on each side by a membrane which adds much to its breadth. The head of the female is of a deep brown, tinged with red; the neck grey; breast and belly white, coverts and scapulars dusky and ash-coloured; the legs dusky. See Tab. IV. *Budi*. N^o 50. Ray and Pennant.

Duck, broad-billed, *Ans Cypripata*, or *Latirostra*, a species of sea duck, known with us by the name of *harlequin*. It is somewhat smaller than the common duck; the beak is remarkably broad, whence its name, and grows broader and rounder toward the end, where it is hollowed like a shield, and the edges of each mandible are pectinated or supplied with thin laminae, that lock into each other when the mouth is closed. The *irides* are of a bright yellow; the head and upper part of the neck, the breast, and the scapulars are white; the back, shoulders, coverts of the wings of a fine sky-blue; those next to the quill-feathers tipped with white; the greater quill-feathers are dusky; the exterior webs of those in the middle are of a glossy green; the tail is short and variegated with black and white; the belly of a bay colour; the feet are

feathers black, and the legs and feet red. The female has the same marks in the wings as the male, but the colours are less bright. The rest of the plumage resembles that of the common wild duck. Ray and Pennant.

Duck, Hook-billed, *Anas adamsi, retrincens*, is of the shape and size of the common duck, but differs from it in the shape of the bill, which is somewhat longer and hooked downwards; and in the head, which is smaller and slenderer. Ray.

Duck, Horn, *Anas carolinensis*, an American duck, described by Nieremberg, and named from the similitude of its note to that of a huntsman's horn. It is very imperfectly described. Ray.

Duck, Indian and Lybian. See Mufrey Duck.

Duck, Marillon, or Grey-headed, *Anas platyrhynchos*, is a small species of *testudine*, somewhat larger than the teal. The bill is of a yellowish brown; the irides gold-coloured; the head of a dusky rust colour; round the upper part of the neck is a collar of white; beneath that a broader of grey; the back and coverts are dusky, with a few white lines; the greater coverts dusky, with a few large spots of white; the breast and belly are white; the tail is dusky; the side above the thighs black; the legs yellow. This is supposed to be the same with the *capo ruffi*. Ray and Pennant.

Duck, Mufrey, *Anas mufreyi*, is the largest species of the duck kind. The general colour both in the male and female is a purplish black, variegated with white, though the female is sometimes quite white. The beak and feet are red. It has red fleshy protuberances about its beak and eyes; its voice is hoarse, and scarce audible, unless when it is angry. Its eggs are remarkably round. Ray and Linnæus.

Duck, black, *Anas nigra*. See SCOTER.

Duck, Burroughs, *Anas Tadorna*. See TADORNA.

Duck, Northern, *Anas arctica* of Clusius. See PUFFIN.

Duck, Sculp, *Anas marila*, is a species of duck somewhat smaller than the common duck, and of a strange diversity of colours, even in the different birds of the same species, inasmuch, that it is not easy to find two perfectly alike in a flock of forty or fifty. The beak is blue, and the most common colours of the other parts are these: the head, and part of the neck, are of a greenish black; the lower part of the neck has some whiteness, and the breast is black; the belly is white, with a mixture of yellow in the lower part, and near the anus it becomes black. The upper part of the neck is a sooty black; the middle of the back is white, variegated with dusky brownish lines, and the rump and tail are brown, as are also the wings, with some transverse streaks of white; the tail is not above two inches long; the legs are bluish. These birds take their name from feeding on *sculp*, or broken shell-fish.

Duck, Long-tailed, *Anas glacialis*, is a species of duck which breeds in the most northern parts of the world, and only visits our coasts in the severest winters. The bill of this species is short, black at the tip and base, and orange-coloured in the middle; the feet are red; the head, throat, breast, and belly, are white; the four middle feathers of the tail are black, and longer than the other, which are white. Linnæus and Pennant.

Duck, Pintail, or Sharp-tailed, *Anas acuta*, or *carduacea*, a species of duck, sometimes called the *cracker* and *scapheasant*, is of the size of the common widgeon. Its head is all over of a ferruginous brown, but behind the ears there is a slight tinge of purple; its neck is somewhat longer than that of the widgeon, and its beak of a bluish black; the head is small, and on each side of it is a white streak which reaches down to the throat; the throat is grey, variegated with transverse lines, as is also the back, but the shoulder-feathers are, in a great measure, black; the tail is grey, with a mixture of white about the edges of the feathers; the two middle feathers are black, and longer than the others, and run out into narrow points, whence this bird has the name of *scapheasant*; the feet are of a lead colour. The female is of a light brown colour, spotted with black. Ray.

Duck, Tuffad, *Anas fuliginea*, is sometimes called *cape negro*, *querquedula cristata*, and the little *marillon*. The bill is broad, of a bluish green, and the hook black; the irides are of a fine yellow; the head is adorned with a thick but short pendent crest; the belly and under coverts of the wing are of a pure white; the quill feathers dusky without; and at their extremities, and part within, white, and the secondaries are white tip with black. The rest of the plumage is black, varied about the head, with purple; the tail is very short, and consists of fourteen feathers; the legs of a bluish grey; the webs black. The female has no crest. Ray and Pennant. For other species of duck, See TEAL and WIDGEON.

Duck's feet, or May apple, *podophyllum*, in *Bistony*, a genus of the *peperomia mangrynia* class. Its charac-

ters are these: the bud of the flower is enclosed in a large three-leaved empalement, in form of a spatula or sheath; it has nine roundish concave petals, plaited on their borders, and smaller than the empalement; and a roundish germen, without a style, crowned by a plaited obtuse stigma. The germen turns to an oval capsule of one cell, crowned by the stigma, and filled with roundish seeds. There is but one species, a native of North America.

Duck's meat, *Limna, or Lenticula*, in *Bistony*, a genus of the *muscaria diandria* class, whose characters are these: it grows in the water, and is seated at the superficies; its appearance is quite simple and foliaceous, and its roots slender, capillaceous, and pellicled. This genus produces male and female flowers, neither of which have any corolla. The calyx is single leaved; the fruit is an unilocular capsule. Boerhaave mentions three species of this plant.

This is a small plant which frequently covers the whole surface of the ponds and ditches, consisting only of small round green leaves, having neither flower nor seed perceivable; only from the middle of the under side of each leaf, small white thready roots.

Duck's meat, is of a cooling, mollifying nature, good to be applied to inflammations, St. Anthony's fire, or the shingles; also for the gout, either applied by itself, or mixed with barley meal. Six ounces of a strong infusion made in white wine, taken for nine days together, is commended as a cure for the jaundice.

The duck's meat is thought to be very cooling and teryifying; some apply it as a cataplasm to ease the gout and inflammation of the parts; but the repelling of the humours is to be feared in these sorts of remedies; for which reason, to assuage the pain of the hæmorrhoids, powder two handfuls of duck's meat with half an ounce of myrrh; put it all in a linen bag, and bathe the piles with the water which drops through the bag.

Duck's meat, *Starry*, in *Bistony*. See CALLITRICH.

DUCKING, or plunging in water. Olaus Magnus tells us, this was a diversion anciently practised among the Goths, by way of exercise; but among the Celts, and Franks, it was a sort of punishment. Tacitus likewise assures us, that it was executed among the ancient Germans, on the lazy and infamous. At Marfille, and Bourbon, their men and women of scandalous life are condemned to the *cale*, as they call it; that is, to be flung up, naked to the shift, in an iron cage, fastened to the yard of a shalop, and ducked several times in the river. The same is done also at Tholouse, to blasphemers.

DUCKING is also a punishment for seamen; who are thrown into the sea from the top of the yard of the main-mast several times, according to the quality of their offence. Sometimes a cannon-ball is fastened to their feet, to make the fall the more rapid.

There is also a kind of *dry ducking*, wherein the patient is only suspended by a rope, a few yards above the surface of the water: this is a species of strappado.

The punishment is usually made public by the discharge of a cannon.

DUCKING is also a penalty, which veteran sailors pretend to inflict on those, who, for the first time, pass the tropic of Cancer, the equator, or the Straights of Gibraltar, in consequence of their refusal or incapacity to pay the usual fine levied on this occasion.

DUCKING-Steel, in our Customs. See CUCKING-Steel.

DUCKUP, a word used at sea by the steerman, or him that is at the helm, when either main-fail, fore-fail, or sprit-fail hinder his sight, so that he cannot see to steer by a land mark, or the like; for then his word is, *duckup* the clew lines of those sails; and as to the sprit-fail, when a shot is to be made by a chaff-piece, and the clew of that sail hinders the sight, they say, *duckup* the clew lines of the sprit-fail; that is, hale the sail out of the way.

DUCT, Ductus, in Anatomy, is applied in a general sense to all the canals, or tubes, in the animal body, as veins, arteries, &c. through which the humours or juices are conveyed.

Duct has also a more immediate application to several particular vessels: as the

DUCTUS Alimentalis, a name given by Dr. Tyson to the gula, stomach, and intestines; all which make but one continued canal, or *duct*. This *duct* he makes the proper characteristic of an animal.

Ductus Adiposi, are little vesicles in the omentum, which either receive the fat separated from the adipose local, or cells, or else bring it to them; for the extreme fineness of these vessels renders it very difficult to trace their origin, or course.

Indeed it remains somewhat doubtful, whether they be hollow, and real *ducts*; or, whether they be not real

fibres, such as are observed in the spleen, along which the liquid fat does, as Dr. Drake expresses it, drill its way, as the easiest it can find. Malpighi, their first discoverer, inclines to the former opinion. All we know for certain, is, that they terminate in little globules of fat, concerning the use and progress whereof, much remains to be considered. Malpighi starts a doubt, whether the adipose *dusti* may not be propagated from fibres which abound in the spleen, or those fibres from them? As also, whether there be not yet an undiscovered communication between the adipose membrane and the omentum.

DUCTS, Aquarii. See **AQUEOUS HUMOUR.**

DUCTUS Clyferi, or Roriferi; the same as *ductus thoracicus*. See **THORACIC.**

DUCTUS Communis Choliductus, a large canal, formed by an union of the *ductus* cysticus, and hepaticus. This *duct*, descending about four inches, discharges itself into the duodenum, by an oblique inflection, which does the office of a valve, in preventing the regrefs of the bile, conveyed hereby into the intestines. See *Tab. Anat. (Splanch.)* fig. 5. lit. k. See **BILE**, and **CHOLDOCHUS**.

The *ductus communis* sometimes opens into the duodenum at the same aperture with the pancreatic *duct*.

DUCTUS Cysticus, or Mamma Cysticus, a large canal, about the bigness of a goose-quill, which arising from the neck of the gall-bladder, about two inches distance therefrom, joins the porus biliaris; and, together with it, constitutes the *ductus communis*. See *Tab. Anat. (Splanch.)* fig. 1. lit. d. fig. 5. lit. g.

DUCTS, Excretorii. See **EXCRETORY.**

DUCTS, Galactophorici. See **GALACTOPHOROUS.**

DUCTUS Hepaticus. See **CYST-HEPATIC.**

DUCTUS Hepaticus, called also *Mamma Hepaticus*, and *Biliary Pore*. See **PARA-BILIARIUS**.

DUCTUS Lachrymales, the excretory vessels of the glandula lachrymales, serving for the effusion of tears. See **LACHRYMALIA**.

DUCTUS Pancreaticus, a little canal, arising from the pancreas, and opening into the duodenum; serving to discharge the pancreatic juice into the intestines. See **PANCREAS**, and **PANCREATIC JUICE**.

This *duct*, being first discovered by Wirtfungus, is frequently called *ductus WIRTUNGIANUS*.

DUCT, Pneum. See **PNEUMATI.**

DUCTUS pneumonici, in *Ichthyology*, the name of a certain *duct* or canal, found in all those fish which have an air-bladder, reaching from that bladder to the orifice of the stomach, or some other part of it. This *duct* is variously situated in the different kinds. Artedi *Ichthyolog.* See **AIR-BLADDER**.

DUCTUS Salivales, the excretory tubes of the salivary glands; serving to discharge the secreted saliva into the mouth. See **SALIVARY DUCT**.

DUCTUS Thoracicus. See **THORACIC DUCT**.

DUCTUS Umbilicalis. See **UMBILICALIS Funiculus**.

DUCTUS Urinari; the same as **URETHRA**.

DUCT, Ductus, in Building. See **CALIDUCTS, VENTIDUCTS, SEWERS, CLOACA, &c.**

DUCTILITY, in Physics, a property of certain bodies, whereby they become capable of being beaten, pressed, drawn, or stretched forth, without breaking; or whereby they are capable of great alterations in their figure and dimensions; and of gaining in one way as they lose in another.

Such are metals, which being urged by the hammer, gain in length and breadth what they lose in thickness; or, being drawn into wire through the holes in iron, grow longer as they become slenderer.

Such, also, are gums, glues, resins, and some other bodies; which, though not malleable, yet may be denominated *ductile*; inasmuch as, when softened by water, fire, or some other menstruum, they may be drawn into threads.

Some bodies are *ductile* both when they are hot and cold, and in all circumstances; such are metals, and particularly gold and silver; other bodies are *ductile*, only when they have a certain degree of heat; such as wax, and substances of the same kind, and glass; and others again, as some kinds of iron, viz. those called by workmen *red-hot*, brass, and some other metallic alloys, are *ductile* only when cold, and are brittle, when hot.

So that we have two classes of *ductile* bodies; the one hard, and the other soft; on each of which we shall bestow some considerations.

The cause of *ductility* is very obscure; as depending, in great measure, on hardness; than which there is nothing in nature we know less of. It is true, we usually account for hardness, from the force of attraction between the particles of the hard body; and for *ductility*,

from the particles of the *ductile* body being, as it were, jointed, and entangled with each other.

Instead of fanciful hypotheses to account for *ductility*, we shall here enjoin the reader with some truly amazing circumstances and phenomena thereof, in the influence of gold, glass, and spider-webs.

Observing, however, that the *ductility* of metals decreases in the following order; gold, silver, copper, iron, tin, lead.

DUCTILITY of gold. One of the properties of gold is, to be the most *ductile* of all bodies; of which the gold-beaters, and gold-wire-drawers, furnish us with abundant proof. Fa. Merenne, M. Rohault, Dr. Halley, &c. have made computations thereof: but they trusted to the reports of the workmen. M. Reaumur, in the *Memoires de l'Academie Royale des Sciences*, an. 1713, took a safer way; he made the experiment himself. A single grain of gold, he found, even in the common gold-leaf, used in most of our gildings, is extended into thirty-six and a half square inches; and an ounce of gold, which, in form of a cube, is not half an inch either high, broad, or long, is beat under the hammer into a surface of 146 and a half square feet; an extent almost double to what could be done in former time. In Fa. Merenne's time, it was deemed prodigious, that an ounce of gold should form 1600 leaves; which, together, only made a surface of 105 square feet.

But the distension of gold under the hammer (how considerable soever) is nothing to that which it undergoes in the drawing iron. There are gold leaves, in some parts, scarce the $\frac{7}{16}$ part of an inch thick; but $\frac{1}{16}$ part of an inch is a considerable thickness, in comparison of that of gold spun on silk in our gold thread.

To conceive this prodigious *ductility*, it is necessary to have some idea of the manner wherein the wire-drawers proceed. The wire, and thread we commonly call gold-thread, &c., which is only silver wire, is first covered over with gold, is drawn from a large mass of silver, usually about thirty pounds weight, into a wire round into a cylinder, or roll, about an inch in diameter, and twenty-two inches long, and covered with the leaves prepared by the gold-beaters, layer over another, till the cover is a good deal thicker than that in our ordinary gilding; and yet, even then, it is very thin; as will be easily conceived from the quantity of gold that goes to gild the thirty pounds of silver: two ounces ordinarily do the business; and, frequently, little more than one. In effect, the full thickness of the gold on the ingot rarely exceeds $\frac{1}{16}$, or $\frac{1}{8}$ part; and, sometimes not $\frac{1}{16}$ part of an inch.

But this thin coat of gold must be yet vastly thinner: the ingot is successively drawn through the holes of sieve I iron, each smaller than the other, till it be as fine, or finer than a hair. Every new hole lessens its diameter; but it gains in length what it loses in thickness; and, of consequence, increases in surface: yet the gold still covers it; it follows the silver in all its extension, and never leaves the minutest part bare, not even to the microscope. Yet, how inconceivable must it be attenuated while the ingot is drawn into a thread, whose diameter is 9000 times less than that of the ingot!

M. Reaumur, by exact weighing, and rigorous calculation, found, that one ounce of the thread was 232 feet long; and the whole ingot 136520 feet, Paris measure, or 96 French leagues; equal to 1264400 English feet, or 240 miles English; an extent which far surpasses what Fa. Merenne, Farcieres, Dr. Halley, &c. ever thought of.

Merenne says, that half an ounce of the thread is 500 toises, or fathoms long; on which footing, an ounce would only be 1200 feet; whereas, M. Reaumur finds it 3232. Dr. Halley makes six feet of the wire one grain in weight, and one grain of the gold ninety-eight yards; and, consequently, the tenthousandth part of a grain, above one third of an inch. The diameter of the wire he found one 186th part of an inch; and the thickness of the gold one 154500th part of an inch. But this, too, comes short of M. Reaumur; for, on this principle, the ounce of wire would only be 2680 feet.

But the ingot is not yet extended to its full length. The greatest part of our gold thread is spun, or wound on silk; and, before they spin it, they flat it, by passing it between two rolls, or wheels of exceedingly well polished steel; which wheels in flattening it, lengthen it by above one seventh. So that our 240 miles are now got to 274. The breadth, now, of these laminae, or plates, M. Reaumur finds, is only one 8th of a line, or one 96th of an inch; and their thickness one 3072d. The ounce of gold, then, is here extended to a surface of 1190 square feet; whereas, as the utmost the gold-beaters can do, we have observed, is to extend it to 146 square feet. But the gold, thus exceedingly extended, how thin must it be! Fa. Merenne

M. Reaumur's calculus, it is found to be one 175000th of a line, or one 210000th of an inch; which is scarce one 1/3th of the thickness of Dr. Halley's gold. But he adds, that this supposes the thickness of the gold everywhere equal, which is no way probable; for in beating the gold-leaves, whatever care they can be taken, it is impossible to extend them equally. This we easily find, by the greater opacity of some parts than others; for, where the leaf is thickest, it will hold the wire the thickest.

M. Reaumur, computing what the thickness of the gold must be where thinnest, finds it only one 315000th part of an inch. But what is the one 315000th part of an inch? Yet this is not the utmost ductility of gold; for, instead of two ounces of gold to the ingot, which we have here computed upon, a single one might have been used; and, then, the thickness of the gold, in the thinnest places, would only be the 630000th part of an inch.

And yet, as thin as the plates are, they might be made twice as thin, yet still be gilt, by only pressing them more between the flatter's wheels, they are extended to double the breadth, and proportionally in length. So that their thickness, at last, will be reduced to one thirteenth, or fourteenth-millionth part of an inch.

Yet, with this amazing thinness of the gold, it is still a perfect cover for the silver's bell eye, or even the bell microscope, cannot discover the least chasm, or discontinuity. There is not an aperture to admit alcohol of wine, the subtilist fluid in nature, or even light itself, unless it be owing to cracks occasioned by repeated strokes of the hammer. Add, that if a piece of this gold-thread, or gold plate be laid to dissolve in aquafortis, the silver will be all excavated, or eat out, and the gold left entire, in little tubules.

It should be observed, that gold, when it has been struck for some time by a hammer, or violently compressed, as by gold wire drawers, becomes more hard, elastic, and stiff, and less ductile, so that it is apt to be crackt or torn: the same thing also happens to the other metals by percussion and compression. But ductility and tractability may be restored to metals in that state, by ANNEALING them, or making them red hot. Gold seems to be more affected by percussion and annealing, than other metals.

As to the DUCTILITY of soft bodies, it is not yet carried to that pitch. The reader, however, must not be surpris'd, that, among the ductile bodies of this class, we give the first place to the most brittle of all other, glass.

DUCTILITY of Glass. We all know, that, when well penetrated with the heat of the fire, the workmen can figure and manage glass like soft wax; but what is most remarkable, it may be drawn, or spun out into threads, exceedingly fine and long.

Our ordinary spinners do not form their threads of silk, flax, or the like, with half the ease, and expedition, as the glass-spinners do threads of this brittle matter. We have some of them used in plumes for children's heads and divers other works, much finer than any hair, and which bend and wave like it with every wind.

Nothing is more simple and easy than the method of making them: there are two workmen employed; the first holds one end of a piece of glass over the flame of a lamp; and, when the heat has softened it, a second operator applies a glass hook to the metal thus in fusion; and, withdrawing the hook again, it brings with it a thread of glass, which still adheres to the mass; then, sitting his hook on the circumference of a wheel about two feet and a half in diameter, he turns the wheel as fast as he pleases; which, drawing out the thread, winds it on its rim; till, after a certain number of revolutions, it is covered with a skin of glass-thread.

The mass in fusion over the lamp, diminishes insensibly; being wound out, as it were, like a peloton, or cluc of silk, upon the wheel, and the parts, as they recede from the flame, cooling, become more coherent to those next to them; and this by degrees: the parts nearest the fire are always the least coherent, and of consequence, must give way to the effort the rest make to draw them towards the wheel.

The circumference of these threads is usually a flat oval, being three or four times as broad as thick; some of them seem scarce bigger than the thread of a silk-worm, and are surprizingly flexible. If the two ends of such threads be knotted together, they may be drawn and bent, till the aperture, or space in the middle of the knot, do not exceed one 4th of a line, or one 48th of an inch diameter.

Hence M. Reaumur advances, that the flexibility of glass increases in proportion to the fineness of the threads; and that, probably, had we but the art of drawing threads as fine as a spider's web, we might weave flasks and cloths heretofore. Accordingly, he made some experiments this way; and found he could make threads fine enough, as fine, in his judgment, as any

spider's web; but he could never make them long enough to do any thing with them.

DUCTILITY of spider-webs. See WEA.

DUEL, a single combat, at a time and place appointed, in consequence of a cartel, or challenge.

The word is usually derived from *dullum*, used by the barbarous Latin writers, *quasi durum bellum*.

Duels were anciently allowed by common law, in cases where proof could not be had. In which view, Fleta defines *duel*, *singularis pugna inter duos ad probandum veritatem litis*; *et qui vici, probo esse intelligitur*. Stat. de Fimib. Levat. 27 Edw. 1.

This *duelling* was to general a method of terminating differences among the nobility, that even ecclesiastics, priests and monks, were not excused from the time; only, to prevent their being stained with blood, they obliged them to produce champions to fight in their stead; as is shewn at large by father Dacier, in his *Spicilegium*, tom. viii.

None were exempted from these legal duels, but women, sick people, and cripples; and such as were under twenty-one years of age, or above sixty.

The custom was, for the two champions to enter a list, or small enclosure, appointed by the authority of the ordinary judge, not only on criminal occasions, but on some civil ones, for the maintenance of their right.

The monk Sigebert even relates, that a question on a point of law being presented to the emperor Otto I. viz. whether representation had place in direct succession? and the doctors finding themselves embarrassed in the resolution thereof, the emperor remitted the decision of so critical a point to the judgment of arms, and pitched on two bold fellows to maintain the *pro* and the *contra*. The victory fell to him who contended for representation; in favour of whom a law was immediately made, which is in force to this day.

This custom came originally from the northern nations; among whom it was usual to end all their differences by arms, as we are assured by Paterculus. It afterwards passed as a law among the Germans, Danes, and Franks; especially after Consecrad, king of the Burgundians, admitted it in lieu of swearing. Towards the conclusion of the fifth century, M. Godeau, in his history of the church, VII. cent. says, it was the Lombards who first introduced into Italy the barbarity of single combat, whence the custom spread throughout the rest of Europe. This mode of trial was introduced into England, among other Norman customs, by William the Conqueror; but was only used in three cases, viz. one military, in the court-martial, or court of chivalry and honour; the second, criminal, in appeals of felony; and the third, civil, upon issue joined in a writ of right, which was the only decision of such writ of right after the Conquest, till Henry II. with consent of parliament introduced the alternative of the grand assize, or a peculiar species of trial by jury. See BATTLE.

The preparation for the combat, and the process of it, are described under the article COMBAT. We shall only farther observe, that when the day of combat was come, they made choice of four cavaliers to guard the field; and performed diverse ceremonies, prayers, oaths, &c. described by Pasquier, and other authors, and quoted by Du-Cange, who mentions an ordinance of king Philip the Fair, in 1265, prescribing the several rules, conditions, and ceremonies, to be observed herein.

The method of trial by *duel* was instituted as a way of consulting Providence, to learn who was the criminal; and it was imagined, that God, thus interrogated, would not fail to declare himself in favour of the innocent. But it happened so often, that the unjust secular came off victorious; that they at length began to be convinced, they must not prescribe to his wisdom, the necessity of interrupting the course of second causes. This was giving rules to murder, and disguising assassinations under method and measure.

Saxo-Græmaticus observes, that as early as the year 981, the kings of Denmark had abrogated the proof by *duel*; and in lieu thereof, appointed the proof by red-hot iron, which was also annulled in its turn.

But duels were condemned before by a council held at Valencia, in 855, where the person who killed his enemy, was excommunicated; and the person killed was pronounced unworthy of burial. Afterwards, the popes Nicolas I. Celestine III. and Alexander III. likewise interposed; and Frederick I. and II. prohibited them in Germany; Louis VII. began to restrain them in France, in the year 1168; and St. Louis proceeded to abolish them, but his ordinance, A. D. 1266, only took place in his own territories, and not in those of his vassals. After his example, the counts d'Auvergne and Poitou, and several other lords, forbade them likewise. Philip the Fair following the footsteps of his grandfather, St. Louis, at one time forbade all gages, or pledges of battle; and

and yet be permitted them in four cases, in the ordinance above mentioned of the year 1306. The last *duel* of note was in the year 1547, before king Henry II. between Jarnac and Chastelligne, mentioned by Thuanus, and de Serres.

In England, the trial by *duel* is disused; though the law on which it is founded is still in force. It appears from Madox's History of the Exchequer, that trials of this kind were so frequent in England, that fines paid on these occasions, made no inconsiderable branch of the king's revenue, vol. i. p. 349. The last trial of this kind was appointed in the year 1631, between Donald lord Rey, or Rhee, appellant, and David Ramsay, respondent, in the painted chamber at Westminster. But that quarrel terminated without bloodshed, being accommodated by Charles I. as was also another of the same kind in 1571, by the interposition of Queen Elizabeth. Another instance occurs seven years after that in 1631. Rushworth's Observations on the Statutes, &c. p. 266. See BATTLE and COMBAT.

DUEL is also used for a single combat on some private quarrel or occasion. See CHALLENGE.

The *duel* must be premeditated; otherwise it is only a rencounter.

The folly, or rather madness, of *duelling* reigned for some ages in France; where the flower of the noblesse perished thereby. It is one of the glories of the late Louis XIV. to have used all his power and authority for abolishing *duels*. The severe edicts and laws he made against *duellists*, have, in a great measure, put a stop to the custom.

Deliberate *duelling* is by the law of England a species of murder; and accordingly, it charges both the crime and punishment of murder on the principals; and as some say, on their seconds also. Blackst. Com. vol. iv. p. 199. And yet, as Dr. Robertson observes, so powerful is the dominion of fashion, that neither the terror of penal laws, nor reverence for religion, have been able entirely to abolish a practice unknown among the ancients, and not justifiable by any principle of reason; though, at the same time, it must be admitted, that, to this absurd custom we must ascribe, in some degree, the extraordinary gentleness and compliance of modern manners, and that respectful attention of one man to another, which, at present, render the social intercourse of life far more agreeable and decent than among the most civilized nations of antiquity. Hist. Ch. vol. iii. p. 16, &c. 8vo.

DUKE, *Dux*, a sovereign prince, without the title, or quality, of king. Such are the duke of Lorraine, duke of Holstein, &c.

The word is borrowed from the modern Greeks, who call *duces* what the Latins call *dux*.

There are also two sovereigns, who bear the title of *grand-duke*; as, the *grand-duke* of Tuscany, and the *grand-duke* of Muscovy, now called the *czar*, or emperor of Russia. The heir of the throne of Russia is now called *grand-duke* of Russia. The emperor of Germany is *arch-duke* of Austria. The king of Poland assumes the title of *grand-duke* of Lithuania.

DUKE, *Dux*, is also a title of honour, or nobility, the next below prince.

The *duobus*, or dignity of *dux*, is a Roman dignity, denominated a *duobus*, leading, or commanding. Accordingly, the first *duces*, *duces*, were the *duces* or commanders of armies. Under the late emperors, the governors of provinces in war-time were intitled *duces*. In after-times the same denomination was also given to the governors of provinces in time of peace. The first governor under the name of *dux*, was a *dux* of the Marchia Rhenana, or Grisons, whereof mention is made in Cassiodorus; and there were afterwards thirteen *duces* in the eastern empire, and twelve in the western. The Goths, and Vandals, upon their over-running the provinces of the western empire, abolished the Roman dignities wherever they settled. But the Franks, &c. to please the Gauls, who had long been used to that form of government, made it a point of policy, not to change any thing therein; and accordingly they divided all Gaul into duchies and counties; and gave the names sometimes of *dukes*, and sometimes of counts, *comites*, to the governors thereof.

In England during the Saxons time, Camden observes, the officers and commanders of armies were called *duces*, *duces*, after the ancient Roman manner, without any addition. After the Conqueror came in, the title lay dormant, till the reign of Edward III. who created his son Edward, first called the Black Prince, *dux* of Cornwall, which hath ever since been the peculiar inheritance of the king's eldest son, during the life of his father, so that he is *dux natus*, *non creatus*. After whom, there were more made; in such manner as that their titles descended to their posterity. They were created with much solemnity, per

clausum gladii, stipendiis, & simul auri in capite impositionem. However, in the reign of queen Elizabeth, A.D. 1572, the whole order became utterly extinct; but it was revived about fifty years afterwards, by her successor, in the person of George Villiers, *duke* of Buckingham.

Though the French retained the names, and form of the ducal government, yet, under their second race of kings, there were scarce any such things as *dukes*; but all the great lords were called counts, *comites*, or *barons*; excepting, however, the *dukes* of Burgundy, and Aquitaine; and the *duke* of France, which was a dignity Hugh Capet himself held, corresponding to the modern dignity of *maître de palais*, or the king's lieutenant.

By the weakness of the kings, the *dukes*, or governors, sometimes made themselves sovereigns of the provinces trusted to their administration. This change happened chiefly about the time of Hugh Capet; when the great lords began to diminish the kingdom, so that that prince found more competitors among them than subjects. It was even with a great deal of difficulty they could be brought to own him their superior, or to hold of him by faith and homage.

By degrees, what with force, and what by marriages, these provinces, both duchies and counties, which had been rent from the crown, were again united to it. But the title *duke* was no longer given to the governors of provinces. From that time *duke* became a mere title of dignity, annexed to asperson, and his heirs male, without giving him any domain, territory, or jurisdiction over the place whereof he is *duke*. All the advantages thereof now consist in the name, and the precedence it gives.

The *dukes* of our days retain nothing of their ancient splendor, but the coronet on their escutcheon; which is the only mark of their departed sovereignty. They are created by patent, circumscribed of the sword, mantle of state, imposition of a cap, and coronet of gold on the head, and a verge of gold in their hand.

The eldest sons of *dukes* are by the courtesy of England styled *marquises*, though they are usually distinguished from their fathers second title, whether it be *duke*, *marquis*, or *earl*; and the younger sons, *lords*, with the addition of their christian name, as lord James, lord Charles, &c. and they take place of viscounts, though not so privileged by the laws of the land.

A *duke* has the title of *prince*; and being writ to, he is styled, in the heralds language, *most high, potent, and noble prince*. *Dukes* of the blood royal are styled, *most high, most mighty, and illustrious princes*.

DUX, among Hebrew grammarians, is an appellation given to a species of accents, answering to our comma. See ACCENT.

DUKE-DUKES, a quality given in Spain to a grandee of the house of Silva, on account of his having several duchies from the uniting of two considerable houses in his person. Don Rodrigo de Silva, eldest son of Don Ray Gomez de Silva, and heir of his duchies and principautés, married the eldest daughter of the *duke* de l'Infantado; in virtue of which marriage, the present *duke* de Pastana, who is descended therefrom, and is grandson of Don Rodrigo de Silva, has added to his other great titles, that of *duke-duke*, to distinguish himself from the other *dukes*, some whereof may enjoy several duchies, but none so considerable ones, nor the titles of such eminent families.

DULCIFYING, See EDUCATION in Chemist.

DULCIMER, a musical instrument in the shape of a small chest or box, with strings on the lid of it.

DULCINISTS, in Ecclesiastical History. See APOSTOLICAL. **DULCINO**, in the Italian Music, a wind instrument, otherwise called *part fagotto*. It serves for tenor to the hautboy, and is no more than a little bassoon. Bross. Dict. Mus. in voc.

DULCIS *Aqua*, or *Ale*. See ALE.

DULEGE, in Guntery, a peg of wood which joins the ends of the six fellows, which form the round of the wheel of a gun-carriage; and the joint is strengthened on the outside of the wheel by a strong plate of iron called the *dulege plate*.

DULIA, *Angustia*, *Servitus*. See WORKSHIP, LATRIA, and, HYPERDULIA.

DULKAK, among Arabian writers, a fabulous sea monster, in form of a man, riding on an ostrich, which is said to attack ships, and fight with the men on board. Holm. Lex. in voc.

DULMAF a Turkish dish, made of any vegetable, as cucumbers, onions, cabbage leaves, &c. stuffed with forced meat. Pococke's Egypt, p. 183.

DULNESS of hearing. See HEARING.

DULWICH Water, a well-known mineral water near London. It contains a kind of cathartic bitter salt; it seems not to have any iron in it. Phil. Trans. N° 461. § 22.

DUM *non fuit compos mentis*, in *Law*, a writ that lies for one, who alienates any lands or tenements while not of sound memory or judgment, in order to recover the same from the alienor, against whom the writ is taken.

DUM *fact infra ætatem*, in *Law*, a writ which lies for him, who, before he came to full age, made a feoffment of his land, to recover it again of the feoffee. *Fitz. Nat. Br. fol. 302.*

DUMBNESS, the state of a person who wants the natural use of speech.

People born deaf, are said to be all naturally dumb, as not being able to learn words.

Dumbness is sometimes the result of the want, or even the ill conformation, of the tongue. Yet in the third some of the Ephrem. German. we have an account of a book intitled, *Jac. Ralandi Aglossotomographia, five Descriptio Ovis sine Lingua, quod perfecte loquatur.* See **TONGUE** and **MUTE**.

When this disorder arises from defects, it sometimes admits of a cure. See *Phil. Trans.* N° 61, where Dr. Wallace gives an account of two persons deaf and dumb, who were taught to understand and speak a language. And in N° 245, the docteur gives an account of his method for this purpose.

DUN, in the *Mange*, a colour partaking of brown and black.

DUNDAIVER, in *Ornithology*, the name of a water-fowl, esteemed a distinct species of birds, not only by the vulgar, but by the generality of authors, but being in reality no other than the female **MERGANSER** or goosander. This is less than the male; the head and upper part of the neck are ferruginous; the throat white; the feathers on the hind part are long, and form a pendent crest; the back, coverts of the wings, and tail, are of a deep ash-colour; the greater quill-feathers are black, and the lesser white; the breast and middle of the belly are white, tinged with yellow. The wings, both in this and in the male, are very short in proportion to the size of the body; yet they fly along the surface of the water very swiftly. *Ray and Pennant.*

DUNG, in *Agriculture*, &c. All kinds of dung contain some matter, which, when mixed with the soil, ferments therein, and by that fermentation, dissolves the texture of the earth, and divides and crumbles its particles very much. This is the real use of dung in agriculture; for as to the pure earthy part of it, the quantity is so very small, that after a perfect putrefaction, it bears an extremely inconsiderable proportion to that of the earth it is intended to manure.

The fermenting quality of dung is principally owing to the salt it contains; and yet those, or any other salts, applied immediately to the roots of plants, always destroy them. This proves, that the business of the dung is not to nourish, but to divide and separate the terrestrial matter, which is to afford the nourishment to vegetables through the mouths of their roots. And the ceremony of the salts of dung is to great, that the skilful managers of vegetables we have, the florists, have wholly banished the use of it from their gardens. The use of dung should be also forbid in kitchen gardens; for it is possible to succeed full as well without it; and it gives an ill taste to all the roots and plants that are to stand in the earth, in which it is an ingredient. The water of a cabbage raised in a garden, manured with dung, if boiled, is of an intolerable stink; but this is not so much owing to the nature of the plant, as of the manure used to it; for a field cabbage being boiled, the water has scarce any smell, and what it has, is not disagreeable.

It is also a well known fact in the country, that a carrot raised in a garden has nothing of that sweet flavour, that such as grow in the fields have; but instead of this natural reish, the garden one has a compound taste, in which the matter of the manure has no small share. And there is the same sort of difference in the taste of all roots nourished with such different diet. Dung not only spoils the flavour of the esculent vegetables, but it spoils the drinkables into the original compositions of which it enters: they are obliged to use dung to the poor vineyards in *Languesdoe*; and the consequence is, that the wine is nauseous. The poor, who only raise a few vines for the wine they drink themselves, and cannot be at the expence of distilling, have the less of it, but then it is better, by many degrees, than the other; and it is a general observation which the French express in these words, that the poor people's wine in *Languesdoe* is the best, because they carry no dung into their vineyards. Tull's *Horsehoeing* *Husbandry*, p. 10. Another disadvantage attending the use of dung is, that it gives rise to worms. It is for this reason that garden carrots are generally worm-eaten, and field-carrots found; and the same observation will hold good in other vegetables in the field and in the garden. Vegetable and animal dung

are, in fact, only the putrefaction of earth, after it has been altered, by passing through vegetable or animal vessels. Vegetable dung, unless the vegetable be buried alive in the soil, makes a much less ferment in it than animal dung does; but the dung, or putrid matter of vegetables, is much more eligible and wholesome for the esculent roots and plants, than that of animals is. Venomous animals are found to be very fond of dung, and are brought into gardens by the smell of the dung used in them as manure. The snakes usually frequent dung-hills, and lay their eggs in them; and gardens where dung is much used, are always troquipped by toads; whereas the fields where roots are planted, are much less infested by them.

However unnecessary and prejudicial dung is in gardens, it is, however, very necessary in the corn-fields; and little can be done without it in the old method of husbandry. Dung is not so injurious in fields as in gardens, because it is used in much smaller quantities, in proportion to the quantity of soil; and cabbages, turneps, potatoes, and other things growing in fields, and intended only for the food of cattle, will not be injured by dung, tillage, and hoeing all together; for the crops will by this means be the greater, and the cattle will like the food never the worse. Dung is very beneficial in giving very large crops of wheat; and it is found by experience, that the country farmer, at a distance from a large town, can never have so good crops by all his tillage, as those who live in the neighbourhood of cities, where dung is produced in great plenty, and easily had.

The dung used in fields, besides its dissolving and dividing virtue, is of great use in the warmth its fermenting gives to the young plants of the corn in their weakest state, and in the most severe seasons; the lifting of this ferment is not easily determined, because the degrees of heat are very difficult to be judged of when they become small.

The farmers usually understand by the term dung, not only the excrements of animals, with the litter, but every thing that will ferment with the earth; such as the green stalks and leaves of plants buried under ground, and the like; and every thing they add to it, except fire.

The uses of the dung of several animals are sufficiently proved every day. They are used to repair the decays of exhausted and worn-out land, and to cure the several defects in different natural bad soils; the faults of which are as different as the nature of the different dung used to improve them. Some land is too cold, moist, and heavy, and the other too light, and dry; and to improve and meliorate these, we have some dung hot, and light, as sheep's, horse's, pigeon's, &c. and others fat and cooling, as that of oxen, hogs, &c. There are two remarkable qualities in dung; the one is to produce a sensible heat, capable of bringing about great efforts; the other is to fatten the soil, and render it more fertile. The first of these is seldom found in any but the dung of horses or mules; the great effects of which, when newly made, and a little moist, are seen in the kitchen-garden, where it invigorates, and gives a new life to every thing, supplying the place of the sun; and to this, in a great degree, we owe all the vegetable delicacies of the spring. Besides, Horse-dung is the richest of all improvements that can be had in any quantity for poor hungry lands; yet, when either too new, or when used alone, it is very prejudicial to some lands; and if spread too thin on dry lands in summer, it becomes of very little service; the sun soon exhaling all its riches, and leaving it little more than a heap of stubble or dry thush.

Horse-dung is always best for cold lands, and cow-dung for hot ones; but being mixed together, they make a very good manure for both sorts of soils; and for some they are very properly mixed with mud.

Sheep's dung, and deer's dung, differ very little in their quality, and are esteemed by some the best of all dung for cold clays; for this purpose, some recommend the beating of them to powder, and spreading them thin over the autumn or spring crops; at about four or five loads to an acre, after the same manner as ashes, man-dung, &c. are dressed. And in Flanders, and some other places, they horse their sheep at nights in places spread with clean sand, laid about five or six inches thick, which, being laid on fresh every night, is cleared out once a week, and with the dung and urine of the sheep is a very rich manure, and sells at a very considerable price. It is principally used for stubborn lands; but Mr. Quinteney is of opinion, that it is the best of all manure for land in general.

Hog's dung is by many recommended as the fattest and richest of all dung; and is found on experience, to be better than any other kind for fruit trees, apples, pears, and the like. It is also a very rich dung for grass; and is

laid to do as much good in one load, as any other *dung* whatever in two.

The *dung* of pigeons, hens, and geese, are great improvers of meadow and corn land. That of pigeons is unquestionably the richest that can be laid on corn land; but before it is used, it ought to be exposed for some time out of the dove-house to the open air, to take off its fiery heat. It is in general very proper for cold clay lands; but then it always should be well dried before it is laid on, because it is apt to clog in the wet. It is best also to mix it with some dry earth, to break its parts, that it may be spread the more regularly; and it is in itself so very rich and hot, as to bear such an admixture without greatly impoverishing it. This *dung* is also by some recommended as better than any other for asparagus, and strawberries, and for the propagation and culture of the tender garden flowers. The *dung* of pigeons is also particularly recommended by Mr. Gentil for those trees whose leaves are apt to turn yellow, if they grow in cold soils; but for this use, it should first lie three years in a dunghill, and then be applied sparingly in autumn, laying about an inch thickness of it at the root of the tree, and suffering it to remain there till the March following.

The *dung* of poultry being hot, and full of salts, tends much to facilitate vegetation, and is abundantly quicker in its operation than the *dung* of animals, which feed on the leaves of plants. It is an observation of Sir Hugh Plat, that one load of grains will enrich ground more than ten loads of common *dung*; and it is easy to infer from hence, that the same grain must needs be of greatly more virtue, when it has passed through an animal body. Human *dung* is also a great improver of all cold and four lands, but succeeds best when mixed with other *dungs*; or earth, to give it a fermentation. But for all stubborn clayey soils, there is no manure so good as the cleaning of London streets; the parts of tough land will be more expeditiously separated by this than by any other compost; and where it is to be had, it is of the greatest value both for field and garden land. Miller's Gard. Dict.

DUNG, GASE. This is a very valuable manure, and as useful to the farmer as pigeon's *dung*, or that of any other fowl. The ancients thought otherwise, and condemned it as prejudicial both to corn and grass; and many are of the same opinion still, but without any foundation in fact. Indeed where corn is high, and when grass is ready to be mown, these birds, if they get among it, will do great damage, by treading it down with their broad feet; but their *dung*, instead of being hurtful to the land, does it great service. Near Sutton, in Nottinghamshire, there is a barren piece of land given by the town for a goose-pasture; the geese have been kept in it many years; and their *dung* has so enriched it, that it is one of the most fruitful pieces of ground in the whole country. There has been an opinion also, that cattle feeding on grass, where these creatures had much dunged the ground, would suffer by it; but it appears from trial, that cattle are most fond of all of those parts of pastures where the geese have dunged most; and that they suffer no alteration by it, except the growing fat upon it. The *dung* of fowls in general is very enriching to land. And Fowley Island, in Lancashire, a place so called from the abundance of wild fowl continually found on it, is so enriched with their *dung*, that it fattens sheep in a surprising manner. See COMPOST and MANURING.

DUNG in Medicine, the properties of. The following properties are attributed by medical writers to the several kinds of *dung*.

Neat's *dung*, applied fresh, mitigates inflammations in wounds. The *dung* of goats, especially of such as live on the mountains, drank in wine, cures the jaundice; and exhibited with spices, provokes the menses, and expels the dead fetens. The *dung* of sheep, applied as a cataplasm, with vinegar, cures *pyelitis*, corns, *thym*, and *verrucae*; drank in wine, and spread upon cerate of roses, it serves for the same purpose. The *dung* of wine, dried, and drank in wine or water, stops vomiting of blood, and cures inveterate pains of the sides; drank in vinegar, it is effectual in ruptures and spasms; and applied in cerate of roses, it cures lacerations. The *dung* of hares and asses, mixed with vinegar, repels hemorrhages. The *dung* of cattle, which feed on herbs, dried, infused in wine, and drank, is an excellent remedy for the poison of the scorpion. The *dung* of storks, drank in water, is supposed to be good for the epilepsy; and the *dung* of a vulture, in a suffumigation, is said to expel the dead fetus. The *dung* of mice, pounded in vinegar, and rubbed on the part, cures an *alopexia*; and drank in mulsum, with frankincense, expels the stone; used in a suppository for children, it stimulates the belly

to excretion. The *dung* of dogs, evacuated in the canicular season, dried, and drank in wine, or water, stops a looseness. Human *dung*, applied fresh, preserves wounds from inflammation, and at the same time conglutinates them: dried, and rubbed on the parts with honey, it is reported to give relief in a quinsy. The *dung* of the land crocodile, serves the women as a cosmetic, to render the skin of the face of a lively colour, and shining. James Med. Dict.

DUNG-MATS, or dung-hills, in Husbandry, places where soils and *dungs* are mixed and digested together. For this purpose, it is usual to dig a pit, sufficient to hold the stock of soil the husbandman is capable of making, and to prepare it at the bottom with stone and clay, that it may hold the water and moisture of the *dung*; and it should be so situated, that the drops of hoar or barns may run into it. Into this pit they cast refuse fodder, litter, *dung*, weeds, &c. where they lie and rot together, until the farmer has occasion for it. Where such a pit is wanting, it is necessary to cover the dung with turf, or other stuff to prevent the sun and wind from drawing off its virtues. Compost *dung-hills*, which are formed by a mixture of earth with *dung*, lime, and other manure, are made with least expence on the field for which they are intended.

DUNG-WORMS, a species of fly-worms, of a short and somewhat flat body, found in great plenty among the cow-dung in the months of September and October. These have all their metamorphoses into the fly state, performed within a shell of their own skin.

The fly produced from this worm is one of Reaumur's first class of the two-winged flies; it has a trunk with lips, and has no teeth; it is of the class of those with the ellipsoid bodies; but its body is remarkably long for one of those, and is composed of six rings; its head is very round, and nearly of a spherical form; and is large in proportion to its body; it has antennæ of the bicucular or battle-dore form; its reticular eyes are of a deep chestnut brown; and its three small eyes are placed in the common manner. Its coracel is of a fine blue green; and its back is not easily to be described as to colour, for it is changeable, and seems composed of a violet red, and of a deeper and a paler copper colour. The upper part, or belly, is of a pale yellow, and the legs and saunders of a yet paler yellow. Reaumur's Hist. Insect. vol. iv. p. 350.

DUNGEON, DOWN, in Fortification, the highest part of a castle built after the ancient mode: serving as a watch-tower, or place of observation; and also for the retreat of a garrison, in case of necessity, so that they may capitulate with greater advantage.

The word comes from the French, *donjon*, which signifies the same; and which Fauchet derives from *dominus*, because the dungeon, being the strongest part of the castle, was usually the lord's apartment. Mr. George derives it from *dominus*, or *dominus*, which in some ancient writings we find used in the same sense. Du-Cange derives the appellation from *dans est celt adificatum*, which the barbarous writers have altered into *dungs*, *dangers*, *dagres*, *dagres*, *dagres*, and *domine*.

In some castles, as that of Vincennes, &c. the *dungeon* serves as a prison for persons they would have the most securely kept; whence the general use of our word *dungeons* for a dark close prison under ground.

DUNKERS, in Ecclesiastical History, a religious sect at Ephrata or Dunker town, near Lancaster, in Pennsylvania, which took their rise about fifty years ago, and consisting mostly of Germans. Their name is said to be derived from their mode of baptizing new converts, which is by dipping, after the manner of the Anabaptists. Their habit is a kind of long coat or tunic, made of linen, for the summer, and woolen for the winter, reaching down to the heels, with a sash or girdle round the waist; and a cap, or hood, hanging from the shoulders, resembling the dress of the Dominican friars. The men have neither the head nor beard. The men and women have distinct habitations and governments: they have for this purpose erected two wooden buildings; in each of which there is a banqueting-room, and an apartment for public worship; so that they never meet together even at their devotions. They live chiefly on roots and vegetables, and eat no flesh, except on occasion of their love-feasts, when the brethren and sisters dine together. The *Dunkers* allow of no intercourse between the brethren and sisters, not even by marriage; a regulation not very favourable to their subsistence and increase; and if any break through this restraint, and marry, they are removed from communion with the unmarried, to a place about a mile distant, called Mount Zion. Their principal tenet is said to be, that future happiness is only to be obtained by penance and mortification in this life; and that as Jesus Christ, by his meritorious sufferings, became

became the redeemer of mankind in general, so each individual of the human race, by a life of abstinence and restraint, may work out his own salvation.

DUNLIN, in *Ornithology*, an English name of a bird of the snipe-kind, or the *TRINGA alpina* of Linnæus. It is of the size of the smaller snipe; its back is furrowed; its belly is white, variegated with large black spots; the head, back, and upper part of the neck, are ferruginous, marked with black spots; and the lower part of the neck is white, marked with short dusky streaks; the tail is ash-coloured; the legs black; and the toes divided to their origin. It is common in watery places, and on the sea-coasts in the northern counties of England, and picks up its food out of the mud. They are esteemed a great delicacy. Ray's *Ornithology*, p. 226.

DUNNAGE, in *Sea-Langage*, a quantity of faggots, boughs of trees, or other loose wood, laid in the bottom of a ship, either to raise the heavy goods which might make her too stiff, or to keep the cargo sufficiently above the bottom, that it may receive no damage from the water, if the ship should prove leaky.

DUNTER-GOOSE, a species of the wild goose, found in Zealand. Pall. Trans. N° 473. § 8. See *Cuthbert Duck*.

DUO, in *Music*, a song, or composition, to be performed in two parts only; the one sung, and the other played on an instrument; or by two voices alone.

Duo is also when two voices sing different parts, accompanied with a third, which is a thorough bass. Unisons and octaves are rarely to be used in *duet*, except at the beginning and end.

DUOBUS, *Pickle* *ex*, in *Medicine*. See **PILLS**.

DUOVS, *ful dr*, is vitriolated nitre.

DUODENA Arteria, and *Vena*, a branch of an artery, which the duodenum receives from the coeliac; to which answers a vein of the same name, returning the blood to the porta.

DUODENUM, in *Anatomy*, the first of the *intestina tenuia*, or small guts; being that which receives the food half chylified from the stomach. See *Tab. Anat. (Splanchn.)* fig. 1. lit. b and c. fig. 2. lit. c.

It has its name *duodenum*, as being above twelve fingers breadth long; on which account, some call it *didactylylon*.

The *duodenum* arises from the pylorus, or right orifice of the stomach; whence descending towards the spine, from right to left, quite straight, it terminates where the circumvolution of the rest begins.

Its coats are thicker, and its cavity or canal is less than any of the other intestines. At its lower end are two canals opening into its cavity, one from the liver, and gill-bladder, called the *ductus communis choledochus*; and the other from the pancreas, called *pancreaticus*.

The *duodenum* is quite straight; but the intestine jejunum makes divers windings and inflexions; the reason is, that the bile and pancreatic juice, mixing at the beginning thereof, or at the end of the *duodenum*, would otherwise precipitate not only the gross parts of the excrement, but also the chyle itself, too hastily. Brunerus discovered a number of small glands in the *duodenum*, which discharge a plentiful lymph; so that the digestion of the aliment begun in the stomach is completed in the *duodenum*.

The description and draughts of the *duodenum*, as given by most anatomists, appearing faulty, Mr. Monro has endeavoured to rectify their omissions and mistakes in the *Med. Ess. Editio*, vol. iv. art. 11.

This intestine is sometimes found so large, as to be called *ventriculus succenturiatus*.

Authors seldom take notice of the *duodenum* as the seat or cause of any particular disease; but its distention and pressure on the many vessels to which it is contiguous, may disturb the functions of the animal economy; and accordingly it is the source of many disorders, which may be relieved by emetics and purgatives.

DUPLA, *Duple Ratio*, is where the antecedent term is double the consequent; or, where the exponent of the ratio is 2:—thus 6:3 is in a *duple ratio*. See **RATIO**.

DUPLE, *Sole Ratio*, is where the consequent term is double the antecedent; or, the exponent of the ratio is 1:—thus, 3:6 is in a *duple ratio*.

DUPLA Sequantia } *Ratio*. See **RATIO**.

DUPLE Superpartientia tertius }

DUPLE Time. See **TIME**.

DUPLICATE, a second instrument, or act in writing; or a transcript, or copy of another.

The word is formed from the Latin *duplus*, or *duplum*, double.

It is usual to send a *duplicate*, when it is apprehended the first dispatch, &c. is lost.

DUPPLICATE, in *Chancery*, is particularly used for a second letter patent granted by the lord chancellor, in a

case where he had formerly done the same. See **PATENT**.

Duplicate Ratio, the ratio between the squares of two quantities. Thus the duplicate ratio of *a* to *b* is the ratio of *aa* to *bb*, or of the square of *a* to the square of *b*.

In a series of geometrical proportions, the first term to the third is said to be in a *duplicate ratio* of the first to the second; or as its square is to the square of the second: thus in 2, 4, 8, 16, the ratio of 2 to 8, is duplicate of that of 2 to 4; or as the square of 2 to the square of 4: wherefore, *duplicate ratio* is the proportion of squares; as triplicate is of cubes, &c. and the ratio of 2 to 8, is said to be compounded of that of 2 to 4, and of 4 to 8.

Duplicate Root, among *Arithmetists*, one composed of two roots. See **ROOT**.

DUPPLICATION, DOUBLING, in *Arithmetic*, and *Geometry*, the multiplying of a quantity, either discrete or continued, by two.

DUPPLICATION of a cube, is the finding of the side of a cube that shall be double in solidity to a given cube; which is a famous problem cultivated by the geometers two thousand years ago.

It was first proposed by the oracle of Apollo at Delphos; which, being consulted about the manner of stopping a plague then raging at Athens, returned for answer, that the plague should cease when Apollo's altar, which was cubical, should be doubled. Upon this they applied themselves in good earnest, to seek the *duplication* of the cube, which henceforward was called the *Delian problem*. The problem is only to be solved by finding two mean proportionals between the side of the cube, and double that side; the first whereof will be the side of the cube doubled, as was first observed by Hippocrates Chius.

Thus let *x* and *z* be two mean proportionals between *a* and *2a*; then $a : x :: x : z$; and $x^3 : a^3 :: z^3 : 2a^3$; therefore $x^3 = 2a^3$. Supposing the side of the given cube *a* to be 10, then the cube root of 20, or 2000, found by approximation, will be the side of the altar required; nearly.

Eutocius, in his comments on Archimedes, gives several ways of performing this by the *mesolabe*. Pappus Alexandrinus, and his commentator Commandine, give three ways: the first, according to Archimedes; the second, according to Hero; and the third, by an instrument invented by Pappus, which gives all the proportions required.

The fleur de Comiers has likewise published an elegant demonstration of the same problem, by means of a compass with three legs; but these methods are all only mechanical.

RE-DUPPLICATION. See **REDUPPLICATION**.

DUPPLICATION Arcuum. See **ARCUM**.

DUPPLICATIONE, in *Anatomy*, a doubling or folding of membranes, or other like part.

Such are the *duplicatures* of the peritonæum, and the omentum, of the pleura, &c.

In the history of the French academy, for the year 1714, an account is given of a young man, who died at the age of twenty-seven years, in the *duplicature* of whose meninges there were found little bones, that seemed to proceed out of the inner surface of the dura mater, and with their acute points stimulated the pia mater.

That *duplicature* of the peritonæum, wherein the ancients placed the bladder, is not found by the modern anatomists. Dionis.

Fabricius ab Aquapendente first discovered the *duplicature* of the cuticula.

DUPLODES. See **CAMBEZON**.

DUPONDIIUS, in *Antiquity*, a weight of two pounds; or a money of the value of two asses. See **AS**.

As the *as*, at first, weighed a just pondo, or libra; the *dupondius* then weighed two. And hence the name.

And though the weight of the *as* was afterwards diminished, and of consequence that of the *dupondius* also; yet they still retained the denomination. See **PONDUS**, and **LIBRA**.

DURA Mater, or *Meninge*, a strong thick membrane, which lines or covers all the inner cavity of the cranium, and includes the whole brain; being itself lined on its inner, or concave side, by the pia mater, or *meninx tenuis*. See *Tab. Anat. (Offel.)* fig. 4. lit. c. fig. 6. lit. c. The *dura mater* sticks very close to the basis of the skull, and its sutures, by the fibres and vessels it sends to the pericranium.

It is fastened to the pia mater, and the brain, by the vessels which pass from one to the other. It gives a coat, or covering, to all the nerves which rise from the brain; and to the medulla spinalis, and all the nerves, which rise from it.

Its surface is rough towards the skull, and smooth towards the brain. It is a double membrane, woven of strong

strong fibres, which may be plainly seen on its inside, but very little on its outside next the skull; it has three processes made by the doubling of its inner membrane. The first resembles a fiddle, and is therefore called *fala*. The second separates the cerebrum from the cerebellum, down to the medulla oblongata, that the weight of the cerebrum may not offend the cerebellum, which lies under it. This process is very strong and thick, and in various beaks for the most part it is bony, because of the violent motion of the brain. The third is the smallest, and separates the external substance of the hind parts of the cerebellum into two protuberances.

In the *dura mater* are several sinuses, or channels, which run between its internal and external membranes; the four principal ones are the sinus longitudinalis; the second and third sinuses are called *latroles*; and the fourth, *transverse*. Besides these there are more of inferior note, mentioned by anatomists, as Dr Verney, Dr. Keilley, &c. Their use is to receive the blood of the adjacent parts from the veins, to which they serve as so many trunks, and to discharge it into the internal jugulars.

The vessels of the *dura mater* are, first, a branch from the carotid, while it is in its long canal, which is displaced in the fore and lower part of the *dura mater*; secondly, an artery, which enters the hole of the skull, called *foramen arteria dura mater*; it is displaced on the sides of this membrane and runs as high as the sinus longitudinalis; the vein which accompanies the branches of this artery goes out of the skull, by the foramen lacuum. Thirdly, a branch of the vertebral artery, and vein, which last passes through the hole behind the occipital apophyses, where they are displaced in the hind part of the *dura mater*. It has also nerves from the branches of the fifth pair, which give it an exquisite sense. It has a motion of systole, and diastole, which is caused by the arteries which enter the skull. No doubt, the great number of arteries in the brain contribute more to it, than those few peculiar to itself; these may assist a little, though not very sensibly, because of their smallness and paucity.

The use of the *dura mater* is to cover the brain, the spinal marrow, and all the nerves; to divide the cerebrum into two, and hinder it from pressing the cerebellum.

Dura Pars. See **PORTIO**.

DURABLE Purification. See **PONTIFICATION**.

DURALE, or DURA, in the Italian Mosaics, signifies hard, harsh, or, more properly, sharp. This name is given to B natural, because its sound is sharp, when compared with B mol, or flat.

DURANTA, in Botany, a genus of the *diandria angiospermia* class. Its characters are these: the flower is of the ringent kind, with one petal, which is erect and concave, and hath an empanclement divided into five equal segments; it hath four stamens, the two middle ones shorter than the others; the perianth which is situated under the flower, afterwards becomes a globular berry, with one cell, enclosing four angular seeds. There are two species, which being natives of warm countries, require a stove to preserve them in winter.

DURATION, in Idea we get by attending to the fleeting, and perpetual perishing parts of succession.

The idea of succession we get by reflecting on that train of ideas, which continually follow one another in our minds, while awake. The distance between any parts of this succession is what we call *duration*; and the continuation of the existence of ourselves, or any thing else commensurate to the succession of ideas in the mind, is called our *own duration*; or that of the thing co-existing with our thinking. So that we have no perception of *duration* when that succession of ideas ceases.

Duration, in Mr. Locke's philosophy, is a mode, or modification of space.

The simple modes of *duration* are any lengths, or parts thereof, of which we have distant ideas: as hours, days, weeks, months, years, time, eternity, &c.

Duration, as marked by certain periods and measures, is what we properly call *time*.

1. By observing certain appearances at regular, and frequently equidistant periods, we get the idea of certain lengths and measures of *duration*, as minutes, hours, &c. 2. By being able to repeat those measures of time as often as we will, we come to imagine *duration* where nothing really endures, or exists: thus we imagine, to-morrow, next year, yesterday, &c. 3. By being able to repeat such ideas of any length of time, as of a minute, year, &c. as often as we will, and add them to one another, without ever coming to an end, we get the idea of eternity.

Time is to *duration*, as place is to space, or extension. They are so much of those boundless oceans of eternity, and immensity, as is set out, and distinguished, from the rest; and thus they serve to denote the position of finite,

real beings, in respect of each other, in those infinite oceans of *duration* and space.

DURATION of action. See **ACTION**.

DURATION of a ellipse. See **ELLIPSE**.

DURATION, in optics. See **SCUTELLUM**.

DURATION of a planet ellipse. See **ELLIPSE**.

DURATI of wood, in Africa. See **SOUND**.

DURE, Door. See **SOUTH-DURE**.

DURESS, Hardship, in Law, is where a person is kept in prison, or restrained of his liberty, contrary to order of law; or is threatened to be killed, maimed, or beaten. In which case, if a person is in prison, or in fear of such threats, make any specialty, or obligation, by reason of such imprisonment, or threats, such deed is void in law; and in an action brought on such specialty, the party may plead, that it was brought by *duress*.

DURION, in Natural History, the name of a fruit common in China and the East Indies, and observed by the Indians the sweet of all fruits; but the Europeans do not esteem it so highly, because of its disagreeable scent. The tree which bears it is large and much branched, and its wood is like that of the maple. The leaves are of a very singular figure, being about six inches long, and fifteen or eighteen inches broad; they terminate in a long and slender point. The upper side of the leaves is of a dusky green, the under side is whitish, with some yellow speckles. The leaves grow on short petioles, which are joined to the stalks by a protuberance or oblong knot. The fruit grows to the large branches, adhering to their midrib by a strong wood stalk. It is of the size of an ordinary melon, and of a conic shape, pointed at the extremity, and is all over beset with prickles resembling those of a hedge-hog; they are green, and very large and thick. When thoroughly ripe, the fruit opens at the extremity into five parts, and the cracks or openings running by degrees up to the top, the inner surface or pulp is discovered. This is of a whitish colour, and of a very agreeable flavour, which may not easily be compared to that of cream and sugar; but it is of a more delicate consistence. This fruit contains in every compartment five large seeds, perfectly resembling the common almond, but that they have no other covering than their own shells. The fruit itself, were the smell as agreeable as the taste, would vie with any fruit in the world; but its very little agreeable scent requires time and custom to enable any one to bear it; but we make the natives wholly disregarded it. The smell is very like that of onions, that have lain in heaps till they are very rotten. The fruit is not only agreeable to the taste, but of a very cordial virtue; but it will intoxicate if eaten in a large quantity, especially such of the fruits as are of a yellowish colour. The natives make debauches with it, as our poorer people do with spirituous liquors. But it is not so easily come at as those, and therefore is very fatal to many families among them, who will sell their liberties for a time to purchase enough of it for a debauch. *Mém. Acad. Sc. Par. 1699.*

DURSIANS, or DURSIANS, in Ecclesiastical History. See **DURSES**.

DURUNGI, in the Materia Medica, a name given by the Arabian writers to the root of the doricum, which is so well described by Aricenna, that we are very well informed of its nature, and find it to be the root of the same plant, which we at this time know by that name.

He says it came to them in pieces, looking like the short joints of a woody root; and that it was either yellow or white on the inside, and of a greyish colour on the surface, and that it was considerably hard and ponderous. The doricum we know at this time has a root that very well answers these characters; and though yellow, when fresh, is very apt to become whitish in decaying.

The name *durungi* is a very plain copy of the Greek name of the same plant, which is not *doricum*, as is supposed from the Latin doricum, but *duruncum*, or *duruncum*. The change of the *z* into a *g*, or the *z* into a *g*, is very common in the turning of Greek into Arabic, or Arabic into Greek names. Thus the word *duruncum* of the Greeks, is the word of the Arabians, and so in a thousand other instances.

The word *durungi*, or, as it is sometimes written *durungy*, is however sometimes made to express another plant, whose shape, as well as virtues, are very different from that above mentioned.

We have at this time two plants of the doricum kind, the one called *thoria*, and the other *anthoria*; the one allowed to be a poison, the other by many esteemed an alexipharmic. The *thoria*, or poisonous kind, is yellow within, and the *anthoria* is white. These may probably be the two kinds of *durungi* mentioned by the Arabians; and if so, the poisonous qualities of the one, and the virtues of the other, stand on a higher record than many have supposed. These two roots were lately sent over

into England among our parcels of gentian, and did much mischief, many people suffering greatly by the bitter infusions in which they made a part. This was probably owing wholly to the thors, or yellow root, which has a poisonous smell; not to the other, which has all the appearance of being innocent.

DUST, minute and almost insensible particles broken off from any hard body.

Those broken from stones, or formed of extremely small stones, are more properly called **SAND**.

The fibrous matter of Des Cartes is a sort of dust produced by the collision of the matter of the second element.

DUST, Gold, and Lead. See the respective articles.

DUST, mica. See **BYALITE**.

DUTCH Cities, Fortifications, Ports, Piers, Telegraphs, Tolls, Tradits, Companies, Monarchs. See the initials.

DUTCHY, in Geography, an appellation given to the dominions of a duke. See **DUCHE**.

DUTCHY-CHIEF. See **COUNTY**.

DUTY, in a moral sense. See **OFFICE**.

DUTY of marriage. See **MARRIAGE**.

DUTY, in *Polity*, and *Commerce*, an impost laid by authority of a prince &c. on merchandises and commodities, either of his own country, or brought from abroad; towards supporting the expenses of the government. See **CUSTOMS, FUNDS, and TAXES**.

The general principle on which all duties and customs should be laid on foreign merchandises, which are imported into their kingdoms, are such as tend to cement a mutual friendship and traffic between one nation and another; and therefore due care should be taken in laying them, that they may answer this end, and be reciprocal in both countries; and they should be laid in such a manner, that the exports of that nation may, at least, be equal to our imports from those nations with which we trade; so that a balance of money should not be sent out of Great Britain to pay for the goods and merchandises of other countries; to the end that no greater number of our land-holders and manufacturers should be deprived of their revenue arising from the product of the lands, and the labour of the people, by foreign importations, than by exportations to such countries. Dict. of Commerce, art. **DUTIES**.

The duties on various kinds of commodities are infinite. The principal are, the

DUTIES of exportation, and importation, paid upon the bringing in, or carrying out, of the diverse kinds of goods, animals, and even persons; agreeable to the tariffs settled between the foreign nations. See **EXPORTATION, &c.**

There is no state in Europe, or perhaps in the world, where the duties of exportation and importation are so many, and so considerable, as in England. The two principal are the duties of tonnage and poundage. The first charged on liquors, in proportion to their measure, and content. See **TONNAGE**. The second on the other commodities, and paid according to their value, settled in a tariff. See **TONNAGE**.

These two duties, which have a long time been on foot in England, were re-established at the restoration of king Charles II. in 1660, upon the parliament's annulling all the laws made under Cromwell, and decreeing the execution of the ancient ordinances.

To these there have been several new duties added since that time; some of them for liquors, and the others on other kinds of commodities.

The **DUTIES on liquors**, are the ancient duty of tonnage, or old subsidy; the additional duty; duty of excise, duty of coinage, the old imposition, the additional imposition, the orphan's money, the duty on French wines, the new subsidy, the duty on Hungarian wines, and the one third, and two third subsidies. See **COINAGE, EXCISE, ORPHAN'S MONEY, SUBSIDY, &c.**

The **DUTIES on other commodities**, are the ancient duty of poundage, the additional duty of 1660, on linens and silks; the new imposition of poundage, called the *impost* of 1660; another imposition of four fifths in 1693; the duty of 25 per cent on French goods, imposed in 1695; the new subsidy of poundage in 1697; another additional subsidy of a third of poundage in 1703; another third in 1704; a duty on fish, oils, and whale-fins, in 1709; another on leather, vellum, and parchment, in 1711; a second on the same goods, in 1712; and lastly, in the same year, a duty on paper, paste-board, and soap. See **IMPOST, POUNDAGE, &c.** and the principal articles of commerce.

The English merchants, it is to be observed, are not obliged to pay these several duties before twelve months; nor foreigners before nine; giving security for the same. Or if they pay ready money, there is a deduction made them of 5 per cent. on the old new third, and two third

Vol. II. N° 104.

subsidy, and on the other duties six, and one fourth per cent. Add, that if these merchandises be again exported into other countries, after they have been entered in England, the duties are returned; though this only within the compass of a year to natives, and of nine months to foreigners. See **ALIEN DUTY**.

In Spain, the duties of export and import are called *dueros de comercio*, and amount to about 5 per cent. of the value of the goods; for instance, the piece of velvet of forty Spanish vases, or yards, pays twenty rials; hats of Vigosa, five rials a-piece; linens, 224 rials per 100 vases; gold and silver laces, 2 rials 3 quarters the mark weight. The duties of exportation are nearly on the same footing.

In Portugal, the duties of importation were anciently the same on all kinds of goods, viz. 18 per cent. of the value. But since the year 1663, silks have been excepted out of the general tariff, and reduced to 12 per cent. For exportation the duties are only 6 per cent.

In Holland, the duties of exportation and importation, are nearly alike; both of them being about the rate of 5 per cent. on the value of the goods. At Hamburg and Bremen, the duties are but a per cent. At Lubek, three 4ths per cent. In Moscow, they are 5 per cent.

At Venice, these duties are 62 per cent. for what the natives import; and 102 to strangers; the duties of exportation are 9 per cent. At Leghorn, the duties of exportation and importation are very inconsiderable; but, with the addition of a number of petty duties, they become as great as at Venice.

In the ports of the Levant, Constantinople, Smyrna, Aleppo, &c. the duties of exportation and importation are nearly on an equal footing, viz. 3 per cent. except to the Venetians and Jews, who pay 5 per cent. The consuls duties are likewise to be added for Smyrna, &c. which are about 2 per cent.

At Cairo, Alexandria, and some other cities of Egypt, the duties are of two kinds: one for goods brought in ships from Europe; the other for those brought by the caravans from Africa. The first are fixed at 20 per cent. the second are arbitrary, but they are always very high. Beside the ordinary duty, they here pay the golden duty, which is the tenth part of what is paid for the first duty. As to duties of exportation, they may be said to pay none, the 12 per cent. being rather the custom house fee, than any duty paid the sovereign.

DUTY, in the Military Art, is the exercise of those functions that belong to a soldier; with this distinction, that mounting guard, and the like, where there is no enemy directly to be engaged, is called *duty*; but marching to meet and fight an enemy is called going on service.

DUUMVIR, a general appellation among the ancient Romans, given to magistrates, commissioners, and officers, where two were joined together in the same function. So that they had almost as many *duumviri*, as they had officers joined two by two in commission. There were *duumviri* to direct the building, repairing, and consecrating of temples and altars; *capital duumviri*, who took cognizance of crimes, and condemned to death; *duumviri* of the marine, or navy; &c. But the most considerable of the *duumviri*, and those usually thus called by way of eminence, were the

DUUMVIRI SACRUM, created by Tarquin, for the performance of sacrifices, and keeping of the Sibyl's books. These were chosen from among the nobility, or patricians; and held their office for life: they were exempted from serving in war, and from the offices imposed on the other citizens; and without them the oracles of the Sibyls could not be consulted.

The commission lasted till the year of Rome 388, when, at the request of C. Licinius, and L. Senuus, tribunes of the people, they were changed into *quæstorii*; that is, in lieu of two persons, the trust was committed to one, who were half patricians, half plebeians.

Sylla added five more to their number, upon which they became denominated *quæstorii*; their body was afterwards much increased, and at length amounted to fifty; yet still it retained the denomination of *quæstorii*. They were entirely abolished under the emperor Theodosius, along with the rest of the heathen superstitions.

DUUMVIRI, the capital, Duumviri Perduelliones, were not ordinary magistrates; but created only on certain occurrences. The first commissioners of this kind were those appointed to judge the surviving Horatius, for killing his sister, after vanquishing the Curiatii.

There were also *duumviri* in the Roman colonies; who held the same rank and authority in their respective colonies, that the consuls held at Rome. They were chosen out of the body of decuriones, and wore the *prætexta*, or robe bordered with purple.

We also read of *municipal duumviri*, whom Vigenere com-

pages to our sheriffs, or rather mayors of towns, whose authority lasted only five years.

DUOMVIRATE, *DUOMVIRATUS*, the magistrature, office, or dignity, of the *duumviri*. See **DUUMVIR**.

DUYT, in *Commerce*, a Dutch copper coin.

DWALE, or **DWAL**, in *Herbals*, the herb-nightshade; used by such as blazon with flowers and herbs, instead of colours and metals, for sable, or black.

DWART. See **PYGMY**, and **STATURE**.

Dwarfs were called *nani* and *nane* amongst the Romans; and were held in such respect, that artificial methods were used in order to prevent the growth of boys designed for *dwarfs*, by enclosing them in a box, or binding them with bandages. Augustus's niece, Julia, was very fond of one of these *dwarfs* called *Sonopus*, who was only two feet and a hand-breadth high.

In the Philosophical Transactions we have well authenticated accounts of two *dwarfs*: one born in Norfolk, who, at the age of twenty-two, weighed no more than thirty-four pounds with all his clothes on, and whose height, including hat, wig, and shoes, was only thirty-eight inches; and another in Wales, who, at the age of fifteen, measured no more than two feet seven inches, and weighed only thirteen pounds, and who, at that early period of life, laboured under all the infirmities and calamities of very old age. Phil. Trans. vol. xlii. p. 67, and vol. xlvii. p. 279.

DWART-TREE, a sort of diminutive fruit-trees, frequently planted in the borders of gardens; thus called from the lowness of their stature.

Dwarf-trees were formerly very much in request in gardens, but since the introducing of espaliers, they are much neglected. The manner, however, of propagating *dwarf pears*, which have been found to succeed the best of any *dwarfs*, is this: they are to be grafted on a quince stock, and that at about six inches above the ground; and when the bud has shot so far as to have four eyes, it is to be stopped, to give rise to lateral branches. Two years after the budding, the tree will be fit to transplant to the spot where they still remain. They should be set at five and twenty, or thirty feet square distance, and the ground between may be sown or planted for kitchen use while the trees are young, only observing not to plant too near their roots. There should be stakes driven down all round the tree, to which the branches must be nailed with lill while they are young, joining them into a horizontal direction, and no branches are to be suffered afterwards to cross one another; and in shortening the shoots, the uppermost eye must always be left upwards. The summer and autumn pears are those which do best in *dwarfs*, for the winter ones never succeed well on them.

Apples are also sometimes planted as *dwarfs*, and are for this purpose most commonly grafted on *paradise stocks*. These spread much less than the *pears*, and therefore need only be set at about eight feet distance. Some also plant *apricots* and *plums* for *dwarfs*; but these being of a more tender constitution seldom succeed well. Miller.

See **ESPALEIR**.

DWARF-TREE. See **DWARF-TREE**.

DYADIC *Adyadich*. See **ARITHMETIC**.

DYE, in *Architecture*, the trunk of the **PEDESTAL**; or that part between the base and the cornice; being so named, because it is frequently made in the form of a cube, or *dye*. See *Tab. Archit.* pt. 24, 25, 26, 27, 28.

It is also called *labe*, by the Italians; and by Virgilus, *truncus*.

DYE is also used for a cube of stone, placed under the feet of a statue, and over its pedestal, to raise it, and then is the *moor*.

DYER'S BUSH. See **BLAZE**.

DYER'S BLUE. See **BLUES**.

DYER'S BRAM, the name of a species of genista. See **BACON**.

DYER'S GREEN. See **GREEN**.

DYER'S WOOD in *Botany*, the *luteola* of Tournefort, and a species of the *regulus* in the Linnaean system. For the generic characters, see *Bals. ROSE*.

It grows in moist parts of the world. The Greeks, of old, used it in dying yellow, as we do at this time, and called it *gynure*, and sometimes *thysois*, that word signifying, with them, several different things which had the property of dying yellow. It was called also by some *relias*, or *rubus*; but those who gave it this name have always distinguished it by some peculiar epithet from the common *relias*, or *rubus*. Pausanias mentions it as an herb used in dying cloths; and Neophytus, and several others, give it a place among the things used to tinge the hair. See **WALG**.

DYER'S YELLO. See **YELLOW**.

DYING, the art, or act, of tinging cloths, stuff, or other matter, with a permanent colour, which penetrates the substance thereof.

Dying differs from bleaching, or whitening, which is not the giving of a new colour, but the lightening of an old one. It also differs from painting, gilding, mablising, and printing, or stamping; because the colours in these only reach the surface.

Dying may be defined, the art of colouring wool, linen, cotton, silk, hair, feathers, horn, leather, and the threads, and webs thereof; with woods, mosses, herbs, seeds, and leaves; by means of salts, juices, fixatives, waters, heats, fermentations, macerations and other processes.

Dying, with regard to the manner of applying the colours, is divided into *dry*, and *wet*.

DYING-HOT, *Oxyphragma*, is that wherein the liquors and ingredients are boiled, before the cloths be dipped therein; or even where the cloths themselves are boiled in the dye.

DYING-HOT, *Oxyphragma*, is where the ingredients are dissolved cold; or at least followed by great cold, before the stuffs be put into them. Vide *Soyuz. D. Cronm. tom. ii. p. 1667*, *see. Tamaris. Salmasii. Hæret. ad Solin. tom. ii. p. 1167*.

DYING, *when and process of*. The dying art is of great antiquity, as appears from the traces of it in the oldest facies as well as profane writers. The honour of the invention is attributed to the Tyrians; though what testifies the merit of it is, that it is said to have owed its rise to chance. The juices of certain fruits, leaves, &c. accidentally crushed, are supposed to have furnished the first hint. Pliny assures us, that, even in his time, the Gauls made use of no other dye. It is added, that coloured earths, and minerals washed and soaked with rain, gave the next dying materials. But the purple, an animal juice, found in a shell-fish called *murex*, *caurum*, and *purpura*, seems from history to have been prior to all of them. This, indeed, was reserved for the use of kings and princes; private persons were forbidden, by laws, to wear the least scrap of it. The discovery of a more solid quality, is said to have been taken from a dog's spittle, having caught one of the purple fishes and squeezed out its precious liquor; which struck the fancy of a Tyrian nymph so strongly, that she refused her lover Hercules any favours, till he had brought her a mantle of the same colour.

Pliny seems to ascribe the invention of the art of dying wools to the Lydians of Sardis: *Lydyrum* *lana Sardibus Lydi*; where the word *inspire* must be understood. But a modern critic supposes a false reading here; and not without reason, for *Lydi*, substitutes *Lydia*, the name of a city on the coast of Phœnicia, where the chief mart of the *purpura* was. Plin. Hist. Nat. lib. vii. cap. 66. Harlow. note. ad loc. Nurra, in lib. Chant. tom. xx. p. 193, 601.

After the Phœnicians, the Sardinians seem to have arrived at the greatest perfection in the dying art; inasmuch that *lana Sardianæ*, *Sardinian dye*, passed into a proverb among the Greeks. Antiphanes in two places, to express a thing red as scarlet, compares it to the *lana Sardianæ*. Salmasius, Palmerius, and Spanheim, instead, for *Sardinian* substitute *Sardianæ*; which they suppose a possessive of Sardis, and to denote *Sardian dye*; but Nurra, in a dissertation expressly on the subject, has strenuously supported the pretensions of his country against this innovation. Antiphan. in *Ascharum*. v. 112. item *Pa. v. 114, 74*. I. Paul. Nurra *Dic. de Variis Lecturis Adagio LAMINA SARDINIA*, in *Archæ. Sardinica*, Flore. 1760. 4to. Le Clerc. Bibl. Chant. tom. xx. p. 187, 601.

Till the time of Alexander we find no other sort of dye in use but purple and scarlet. It was under the successors of that monarch, that the Greeks applied themselves to the other colours; and, invented, or at least perfected, blue, yellow, green, &c. As to the ancient purple, it has been long lost; but the perfection to which the moderns have carried the other colours, abundantly indemnifies them for the loss. In this, particularly in the scarlet and black colours, the French, under the auspices of that excellent minister M. Colbert, seem to have outstripped most of their neighbours. See **COBALT**.

Among the Romans, the *dyshoulis*, *dyshoulis*, were all under the direction of the *dyshoulis*, *dyshoulis*, though they had each their peculiar propolium, as at Alexandria, Tyre, &c. The method of dying and dressing woollen cloths was very imperfectly understood in England, in the year 1608; before which period they were sent white into Holland, where they were dyed and dressed, and from thence brought back for sale. In this year, Sir William Cockayne, an alderman of London, obtained a patent for *dying* and dressing of colours at home; but great confusion arising from this grant, it was revoked in 1615. But in 1667, workmen were introduced into this country from the Netherlands, under whose

whole direction the art was brought to a considerable degree of perfection.

The *dyers* of London make the thirteenth company of the city, incorporated under Henry VI. consisting of a master, warden, and livery. At Paris, and in most of the great cities in France, the *dyers* are divided into three companies; viz. those of the *grand dye*, *du grand & bas teint*, who are only to use the best ingredients, and such as strike the surest and most lasting colours. *Dyers* of the *lesser dye*, *du petit teint*, who are allowed to use the inferior sorts of drugs, which only yield false and fading colours. And silk, wool, and thread *dyers*. All the higher-priced cloths and stuffs are referred to the *dyers* of the first sort: those of less value, particularly such as are not rated at above forty sols the ell in white, are committed to the masters of the *petit teint*. Blue, red, and yellow, are referred more peculiarly to those of the *grand teint*; brown, fallow, and black, are common to both sorts. As to black, it is begun by the *dyers* of the *grand teint*, and finished by those of the *lesser*. It seems there is a tradition among *dyers*, that Jesus Christ was of their profession; which we also find delivered in the *Gospel* by the *infancy* of *Jesus*, though on what ground we know not; but it is hence that the Persian *dyers*, notwithstanding all their Mahometanism, have chosen *Jesus* for the patron of their art; inasmuch that, among them, a *dyer* is called *Cherif*. *See* V. Nostr. Imper. Hoffm. l. tom. i. p. 460. Phil. L. Ant. tom. i. p. 129. New view of Lond. tom. ii. p. 601. *See* Savar. Dict. Comm. tom. ii. p. 168. *See* *Yard*. *Sike* Not. ad Evang. Infant. p. 55. Hirsch. De Stud. Christ. in Mlic. Lips. Obs. 96. 110. tom. v. p. 24.

DYING, rigidius in. There are three things demanded by the Greek chemists to a good dye, viz. *assuetudo*, opening, or rarifying, of the body to be dyed, to dispose it to imbué the colour; *tenax*, the tincture, or dye, itself. *Karax*, or *Σπυδα*, by the Romans called *stercus*, the binding or fixing of the colour, to prevent its fading, or being discharged. Some add a fourth condition, viz. *zardura*, by the Latins called *lumen*, by us *lustre*, or *brilliance*.

Among some, these three were done severally at three different operations, in different liquors, or decoctions: by the first, the stuff was prepared to receive the dye; this was called *apicatura*, and *εργαστη*; by the second, the desired colour was given it; and by the third, the colour was fixed on it. But others did all three at once, with one decoction, and at one dip. Vide *Salmat. Exerc. ad Solin. tom. ii. p. 116*, *seq.*

DYING, theory of, is still far from being thoroughly known, or established; though many facts and observations, and particular processes, have been offered for this purpose. We shall collect the principal of them in the sequel of this article.

The basis of a full history of *dying*, must be a theory of light and colours. Two things, it may be observed, are chiefly aimed at in the inquiry of colours: the first, to increase the *materia tinctoria*; the second, to fix those colours we have.

In order to this, it may be remembered, that some colours are *exanimis*, as those of flowers, the juices of fruits, and those of animals. Others are *inanimis*, and only discovered by the effects which the several species of salts, and other things, have on them.

Concerning the *exanimis* colours of vegetables and animals, and the effects of different salts in changing them from one colour to another, we have many instances in Mr. Boyle's collection and ranged in a new order by Dr. Milner: say, 1. That acid salts advance the colours of flowers and berries; thus they make the infusions of balsam, or pomegranate-flowers, red roses, clove-jelly-flowers, narcissus, pansy-bloom, juleps, and cyana-flowers, of a very fine red; and the juices of the berries of *liquetrum*, of black-cherries, and buckhorn berries, of a much finer red. To the same purpose it is observed, that acid salts make no great alterations upon the white flowers of lily and snow-drops.

2. Urinous salts and alkalis, on the contrary, quite alter the colours of the flowers last named, as well as the juices of the berries above mentioned, from red to green.

3. Urinous salts and alkalis advance, at least they do not hurt, the colours of the juices of vegetable leaves, woods, and roots. Thus urinous spirits and alkalis make the yellow infusions of madder-roots, reds of Brazil wood, purples of liguon naphricum, blue, the red infusion of log-wood, purples; and that of the leaves of loma, red.

4. Acid salts quite alter the said infusions from red, or blue, to yellow.

5. Coloured, which of itself is red, upon the addition of oil of vitriol, an acid salt, strikes the most vivid crimson that can be imagined; and with urinous salts, and alkalis,

it will be again changed into an obscure colour: be-tween a violet and a purple.

6. All red, blue, and white flowers, are immediately, upon the addition of an alkali, changed to a green colour; and thence, in no long process of time, they turn yellow.

7. All the parts of vegetables which are green, will, in like manner, strike a yellow with an alkali.

8. What flowers are already yellow, are not much changed, if at all, by an alkali, or urinous spirit.

9. The blue feed-hulls of *gladium sylvestre*, old gathered, and dry, diluted with water, stain a blue, which, upon the addition of ley, strikes a green; which said green, or blue, being touched with the oil of vitriol, turns a purple; and all these three colours stand.

10. On the tops of the fungus tubulosus are certain red knots, which upon the addition of a ley, will strike a purple, and stand.

As for the latent colours in animals and vegetables, discovered to us by the addition of salts, they likewise are very numerous. We will only mention a few. 1. The milky juice of the lactuca sylvestris cells spinosa, & fuscus asper & laevis, upon the addition of ley, will strike a vivid flame-colour, or crimson; and, after some time, quite degenerate into a dirty yellow.

2. The milk of the carapacea mason, upon the addition of ley, especially if it be drawn with a knife, and have any time stood upon the blade thereof, will strike a purple or blood-red colour, and soon after will change into a dull yellow.

3. The common hawthorn-catepillar will strike a purple, or carnation, with ley, and stand.

4. The heads of beetles, pismires, &c. will, with ley, strike the same carnation colour, and stand.

5. The amber-coloured scolopendra will give, with ley, a most beautiful and pleasant azure, or amethystine, and stand.

It remains to be observed, 1. That in all the instances above mentioned, whether vegetable or animal, there is not one colour truly fixed; though there may be some use made of them as they are. By not truly fixed, we mean, not proof against salt and fire; for what seem to stand, and be ley-proof, are either wholly destroyed by a different salt, or changed into a much different colour; which must needs prove a stain and blemish, when it shall happen in the use of any of them.

2. That both the apparent and latent colours of vegetables are fixable; an instance whereof we may observe in the foot hulls of *gladium*, and the side of the male of the leaves of that plant, after due preparation.

3. It is probable, from the same instance, that we may learn from the colour of some part of the fruit, or seed, what colour the leaves of any vegetable, and the whole plant, might be made to yield for our use.

4. That the latent colours of vegetables are pre-existent, and not produced from the same instance of wood, and likewise from this, that the milky juice of lactuca sylvestris affects of itself a red serum.

5. That the change of colours in flowers is gradual and constant.

6. That the colours of flowers which will not stand with ley, seem to be wholly destroyed by it, and irrecoverable. Thus one part of a violet leaf, upon the addition of ley, is changed very soon into yellow, and will never be revived into a red by an acid salt; but if another part of the same leaf be still green, it will be revived.

7. The dryness seems to be a means, if not of fixing, yet of bringing the vegetable colour into a condition of not whinily and suddenly perishing by the otherwise destroying alkali.

8. That those plants, or animals, which will strike different, yet vivid colours, upon the addition of different salts, and stand as the cochineal, and *gladium*, are of all others to be reckoned the best. Vide Lat. in Phil. Trans. N. 70. p. 292. See also Boerh. Elem. Chym. part iii. tom. ii. p. 467. edit. Leips.

Many more valuable colours may be drawn from the vegetable kingdom, if the world would be at the pains of enquiring more minutely into the properties of plants. Mr. Jussieu observed in the drying of plants between sheets of paper, in order to the making of a herbarium in the common way, that some plants tinged the paper with colours the same with those they naturally possess, and others with different ones; and that many plants in drying assumed a colour which was not natural to them.

Alkanet, wood, the several sorts of gallium, and some of the species of anonis, tinge the papers between which they are dried to a yellowish or reddish colour, because their stalks, or some other part of them, are of that colour. The common rose leaf, or (sun-dew, whose leaves are red, tinges the paper red also; and the rose leaf of Portugal diffuses this tinge through three or four sheets

of paper. The alpine veronica, though green in itself, leaves its mark in red upon the paper; and many of the common leguminous plants always become black in the drying. The common mercury, which is green while growing, becomes blue in the drying; and turnsole has the same change, though it is white in its natural state. One great reason of these changes of colour is, that all paper is impregnated with alum; and this salt may very easily extract, or even alter the colour of plants, whose juices it receives; and in such cases, where the alum is not in sufficient quantity to do this, it is no wonder that it should, however, so far affect the leaves as to turn them black.

On this principle Mr. Jussieu attempted, by means of alum, to separate colours from several plants, not known or used at present among the dyers, which might prove serviceable to them. The first experiments made on this occasion proved, that there were many plants not used at present, which afford colours not at all inferior to those in common use. The experiments the same gentleman tried on the drugs used for *dying* in the Indies, proved very plainly, that they were no way superior in many cases to vegetables of our own growth; and that in order to have the most lively colours from such substances, it is always necessary to have recourse to some salt.

Among the other drugs used abroad in *dying*, there were sent over to Fraunce, on this occasion, certain yellow flowers of the radiated kind, which afforded on trial a very beautiful yellow dye; and Mr. Jussieu found on trying parallel experiments, that there were also yellow flowers in Europe of a like radiated kind, which were capable of affording a like beautiful yellow dye.

The flower which Mr. Jussieu tried these experiments upon, was the common yellow corn maygold, the *chrysanthemum leucanthemum* of Læb. This plant flowers in the middle of July; and Mr. Jussieu drying its flowers between papers at that time of the year, found that they did not lose their colour, as most others do in the operation, but became of a deeper yellow than before. Hence it was easy to judge, that this flower contained a matter proper for colouring; and decoctions being made of it of different strengths, cloths of different kinds, dipped into them, became tinged to a light pale yellow, and kept this colour after being boiled in fair water. A little alum was after this added to the decoctions, and cloths dipped in these became much more lively dyed, the colour being much stronger and more lively. They also imbibed the colour much more speedily from these decoctions; and on boiling afterwards in water, they lost no part of it, but remained as strongly and as lively tinged as before. This experiment was afterwards tried by a dyer, under whose hands it succeeded much better than before with Jussieu, who was unacquainted with the regular methods of the trade. The decoction of the flowers gave a sort of sulphur colour; but linen, woollen, and silk threads, which had the day before been steeped in alum water, received from this decoction a very beautiful and sufficiently strong yellow. Another decoction of the flowers made stronger than the first, tinged a woollen cloth to a greenish lemon colour; and the same decoction gave a bright gold yellow to silk; and a piece of woollen cloth before dyed blue with indigo, on dipping it in this decoction, became of a beautiful deep green. A small quantity of chimney-soot added to the decoction made it tinge cloth to a yellowish brown; and a small quantity of roucou added to the simple decoction produced an olive yellow.

The mixture of several other drugs used to be added to the decoction of the common luteola, or dyer's weed, to vary its tinge, produced the same changes with the decoction of this flower, and abundantly testified its value and use in the *dying* trade. Mem. Acad. Par. 1724.

With respect to the theory of *dying*, it is farther to be observed, 1. That all the materials, which of themselves give colour, are either red, yellow, or blue; so that out of them and the primitive luminous colour, white, all that great variety, which we see in dyed stuffs, arises. 2. That few of the colouring materials (as cochineal, foot, wool-wax, or wood) are in their outward and first appearance, of the same colour, which by the slightest solutions in the weakest menstrua, they dye upon cloth, silk, &c. 3. That many of the colouring materials will not yield their colours without much grinding, steeping, boiling, fermenting, or corrosion by powerful menstrua; as red wood, weld, woad, annatto, &c. 4. That many of the said colouring materials will of themselves give no colouring at all, as copperas, or galls, or with much disadvantage, as uolsa the cloth, or other stuff to be dyed, be first covered or incrustated as it were, with some other matter though colourless, as cochineal; as madder, weld, and brazil, with alum. That some of the colouring materials, by the help of other colourless ones, do strike

different colours from what they would alone, and of themselves; as cochineal, and brazil. 6. That some colours, as madder, indigo, and woad, by reiterated tinctures, will at last become black. 7. That though green be the most frequent and common of natural colours, yet there is no simple ingredient, which is now used alone, to dye green with upon any material; sap-green, the condensed juice of the rhamnus or buckthorn-berry, being the nearest; and this only used by country people. 8. There is no black thing in use which dyes black, though both the coal and foot of most things burnt, or scorched, be of that colour; and the blacker, by how much the matter, before it was burnt, was whiter, as in the famous instance of ivory black. 9. The tincture of some *dying* stuffs will fade even with lying, or with the air, or will stain even with water; but very much with wine, vinegar, urine, &c. 10. Some of the dyers materials are used to bind and strengthen a colour; some to brighten it; some to give lustre to the stuff; some to discharge and take off the colour, either in whole or in part; and some out of fraud, to make the material dyed, if costly, to be heavier. 11. Some *dying* ingredients, or drugs, by the coarseness of their bodies, make the thread of the dyed stuff seem coarser; and some by sinking them, smaller; and some by levigating their superficies, finer. 12. Many of the same colours are dyed upon different stuffs with different materials; as red-wood is used in cloth, but in filks; annatto in silk, not in cloth; so that they may be dyed at several pieces. 13. Browering, and washing of stuffs to be dyed, is to be done with appropriate materials; as sometimes with ox-galls, sometimes with fullers earth, sometimes with soap: this latter, however, is pernicious in some cases, where pot ashes will stain or alter the colour. 14. Where great quantities of stuff are to be dyed together, or where they are to be done with great heat, and where the pieces are very long, broad, thick, &c. they are to be differently handled, both in respect to the stuffs and ingredients. 15. In some colours and in some tinging liquor must be boiling; in other cases it must be warm, in some it may be cold. 16. Some tinging liquors are fitted for use by long keeping; and in some the virtue wears away by the same. 17. Some colours, or stuffs, are best dyed by reiterated dippings ever into the same liquor at several intervals of time; and some by continuing longer, and others for a shorter time therein. 18. In some cases, the matter of the vessels wherein the liquors are heated, and the tinctures prepared, must be regarded; as that the kettles be pewter for bow-dye. 19. Little regard is had how much liquor is used in proportion to the *dying* drugs; the liquor being rather adjusted to the bulk of the stuff, as the vessels are to the breadth of the same; the quantity of *dying* drugs being proportioned to the colour higher or lower, and also to the stuffs; as likewise the salts are to the *dying* drugs. Concerning the weight which colours give to filks, for in them it is most taken notice of, as being sold by weight, and being a commodity of great price; it is observed, that one pound of raw silk loses four ounces by washing out the gums, and natural forces. That the same scoured silk may be raised to above thirty ounces from the remaining twelve, if it be dyed black, with certain materials. That the reason why black colour may be dyed the heaviest is, that all ponderous drugs may be dyed black, being all of colours lighter than it; whereas, perhaps, there seem to be few or no materials wherewith to increase the weight of silk, which will consist with fair light colours; such as will having been used, as white arsenic to carnations.

Of things used in *dying*, especially black, nothing increases weight so much as galls; by means whereof black silks recover the weight which they lost by washing out their gum. Nor is it counted extraordinary, that blacks should gain about four or six ounces in the *dying* upon each pound. Next to galls, old fuller increases the weight about 1½. Madder about 2½ ounce in the pound. Weld half an ounce. The blue fat, in deep blues of the fifth stuff, adds no considerable weight. Neither do logwood, cochineal, or annatto; nor even copperas of itself, where galls are not used. Slipp adds much to the weight, and gives a deeper black than copperas, which avoids a good excuse for the dyers that use it. Petty's Appar. to Hist. of Dying, ap. Sprat. Hist. R. S. p. 302.

There is great reason to believe, that the art of *dying* might be carried to much greater perfection than it is at present, if the attempts to improve it were in proper hands, and the persons employed in it could be enabled to set out with all the knowledge there is at present in regard to its several materials, and their manner of use, as a fond of real facts on which to ground future discoveries. This, however, seems difficult to be brought about, for

for the people who exercise the art generally are acquainted only with a certain set of rules, which though they know not why they follow, yet they will not depart from them, and esteem every thing a loss of time that can be proposed to them as improvement. They keep their knowledge also a close secret from those who might be expected to improve upon it, and usually one man trades only in some one part of it, without any knowledge of the rest. Hence the difficulties attending the acquiring of a knowledge of the first principles of the art are very discouraging, but they are not insurmountable. The idea which presents itself most naturally to us, as to the manner in which stuffs are dyed, is, that the colouring particles which swim in the liquor, immediately attach themselves to the surface of the body that is plunged into it, and there adhere in so firm a manner, that there is no removing many of them without wholly taking off the surface of the body. The barely plunging a white substance into a coloured liquor is not however sufficient for the dyeing of it in many cases. Indeed there are only a few colours which will strike with this ease and facility; and the others require that the matter to be dyed should have first received the particles of another fluid, which is in most cases a solution of alum and tartar in common water. And, according to the nature of the colour that is to be given the stuff afterwards, the alum is put in in large quantities, or the stuff boiled in the liquor a longer or a shorter time. After boiling in this liquor, a stuff is in the proper condition to receive the greater part of the common colours; but for blue, stuffs require no preparation at all; and for scarlet, the liquor in which they are first boiled is made without alum.

The manner of the stuff to be dyed makes it necessary also to change the liquor in which it is to be boiled, or to vary the ingredients; and the greatest naturalist, without a mechanical knowledge of *dyeing*, would be amazed to see, that if a beam of white wool, and another of white cotton, be plunged together into the scarlet dye, and then even after they have both received the same previous boiling and preparation, the beam of cotton would come out of the liquor as white as it was put in, while the wool comes out tinged to a beautiful fire colour. The dyer, however, fears this every day, without any admiration of the cause, and never troubling his thoughts about the manner in which it is done. He dyes it daily to dye any thing woollen to a scarlet colour, leaving a part white; in order to which, he knows there requires no more than that the part to be left white should be of cotton.

Mr. Dufay supposing this to be owing to the cotton's imbibing much more slowly than the wool, the liquor in which they are both previously boiled to make them receive the colour, as the cotton is well known not to take wet so soon as wool, ordered a sort of cloth to be woven, the warp of which was wool, and the wool cotton; and sending this to the fuller's, the two fullnesses were to well blended together, that it became impossible for the one to receive the impregnation of any liquor without the other. With all these precautions, however, the whole came out of the scarlet dye in the same condition as if nothing had been done, the cotton remaining wholly white, and the wool being marked with fire colour and white; so that it may be esteemed a certain fact, that the colour of cochineal cannot be given to cotton by the means of acids; the same also holds good of kermes and gum lac, both which are used instead of cochineal to dye in scarlet; but neither of these, any more than the cochineal, will dye cotton. It is not to be concluded from hence, however, that cotton cannot be dyed scarlet by these substances; the whole is, that it requires a different treatment; and as wool, to take the scarlet dye, requires only to be first impregnated with tartar, cotton requires to be first impregnated with alum, as wool does, for the generality of the other colours. The acid of seal-fish, of vitriol, vinegar, and verjuice, all serve to dye wool to a scarlet with cochineal, but none of these will make it give any tinge to cotton, to which alum alone can serve.

The same dye will give very different colours to the different parts of a cloth, which have been differently prepared. And this gentleman showed before the academy a piece of cloth, which he had carefully prepared in a different manner in the different parts, which being all plunged together in the dye, when taken out and dried was found to be of a dirty red in that part where it had not been impregnated with any thing; and in the other parts, where it had been differently impregnated, was found of all the degrees of red, from a pale damask rose colour to the deepest scarlet, and this while it had in every part been dipped an equal time in the same dye. That equally holds good of the other colours. And in these experiments the dirty colours given to each parts of

the cloth as have received no previous impregnation, will be washed away, and quite carried off, while the others remain in all their perfection.

Another circumstance very worthy attention in the *dyeing* of scarlet is this, that the dye is evidently composed of a clear or common water, in which the colouring particles are suspended, and from which it is easy to suppose that they are separated and applied to the stuff in *swims*. As this is naturally supposed to be the case in regard to all colours, so it appears very evidently to be a fact in this, since the colouring particles adhere in such quantities to the matter, and separate themselves so readily and perfectly from the water, that after an hour and half's boiling of the dye with a proper quantity of the stuff in it, the whole coloured matter shall be attached to the stuff, and the remaining liquor be only clear water; and what might appear wonderful in this, that all the boiling in the world will never dissolve any of the colour from the stuff, or occasion its being received into the water again. It might be supposed that this was wholly owing to the particles of stuff, which had been imbibed into the stuff in its prior preparation; that these attracting the particles of the colour to the stuff, while the water of the dye had none of them to cause such an attraction in it, they did not remain in it. But this appears not to be the case, but that the stuff will attract the colour, whether it be previously prepared, or the preparation and the dye be all one act; since the dyea sounding dye scarlet at once in this manner, only plunging the stuff into a dye made of cochineal, a solution of alum mixed in a large quantity of water, with a small quantity of talc, manna, and cream of tartar. All these ingredients are mixed together before the stuff is put in; yet after it has boiled about an hour and a half, all the colour is in the stuff, and the liquor is become colourless as water. The effect is the same in the dyes made of madder and indigo for *red* and *blue*, and indeed in the greater part of other colours; but as the ingredients of these are not to pure as the cochineal, and there are usually many heterogeneous particles among them, the liquor does not become to wholly colourless in this, as in the case of the scarlet. But the dyer, who well know that so long as there is any colour left in the liquor, so long the stuff will be polluted by remaining in it, always take small quantities out of it, and examining it by pouring it gently down against the light, they know when it is that the stuff has received all the mixture it can, by there being no more colouring matter suspended in the dye.

Experience shows, that all colours do not attach themselves with equal readiness to the stuff, or remain equally firmly united to it. Wood, indigo, cochineal kermes, and many other colours, never reach farther than the surface of the stuff. The liquor of the dye penetrates indeed perfectly through the body of it, but the colouring particles stopping at the surface become entangled there, and never penetrate, at least not in any great quantity, to the central part, which remains either quite white, or only very slightly tinged. This however only happens to such stuffs as are thick, and of a very close texture; others are coloured throughout. And this is only the case in regard to some dyes, not to all sorts, since the most of the wood colours penetrate wholly through the stuff be it ever so thick, and colour it equally every where. Whence it seems probable, that the colouring particles of the woods are either more minute and fine, or much more intimately blended with the water, than those of cochineal, indigo, and such others as do not penetrate beyond the surface.

It might seem strange, that the stuffs which are thus externally coloured on the surface, should not afterwards, by the continual boiling of the water, have the colouring particles carried farther down into the body, as the water continually penetrates the whole from each surface to the centre, and might naturally be expected to carry a part of the colouring particles in along with it. But if we consider the whole process from the beginning, we find that the colouring particles are strongly attracted by the stuff, and force at all by the water. Whence they almost immediately leave the water, and attach themselves to the first part of the stuff they come in contact with, which is its surface; and when once fixed there, it is no wonder that the particles of water, ever so long pushing by them, do not attract or take them away from this surface, as they must do in order to carry them in; since we have before had proof, that their attraction to the water is greatly weaker than that to the stuff. And the difference between the wool and the cotton, the one receiving, and the other not receiving at all the coloured particles in its natural state, or with the same impregnation, by means of which the other does, forms a resolvable into the same principle, that though the attraction in the wool be much greater in regard to the coloured particles

particles than that of the water, and therefore it robs the water of them; yet the attraction in cotton being less than in water, the colouring particles remain in the water without any tendency to attach themselves to the cotton. *Mem. Acad. de Paris. 1737.*

M. Helio's theory of dyes is, that the colouring particles are fixed into the pores of fluids chiefly by means of a vitriolated tartar, which he believes to exist in each species, to be produced by the acid of alum and alkaline salts of tartar in the process for red and yellow dyes, to exist originally in the potash employed in the blue dye, and in the stucco and rosin employed in the root-coloured dye. He supposes the pores of the stuff are cleaned and enlarged by the preparatory salts, and by the boiling water, so as to receive the colouring particles, which particles are afterwards detained by the contraction of the pores occasioned by cold and farther, that these pores are lined with a false crust of vitriolated tartar, or of tartar; which salts being difficultly soluble in water, retain firmly the colouring particles. But this theory, says the ingenious translator of the Dictionary of Chemistry, cannot be admitted, when we consider that vitriolated tartar does not exist in any of the materials used in those of the processes for dyes, as in the root-coloured materials, from which the vitriolated tartar can be obtained, and by accident all they have been by burning reduced to alkali; and even that the quantity is exceedingly small; that although common potash generally contains some vitriolated tartar, yet M. Helio has not shown that pure fixed alkali is capable of producing the same effect; and finally, that vitriolated tartar, and tartar, although they require much water to be dissolved, are yet soluble by water; and therefore if the colouring particles were fixed chiefly by means of these salts, they might be washed out by a large quantity of water, which is contrary to experience. The above mentioned writer suggests the following conjectural observations on this subject; that the colorific particles of most substances used in dyes seem to be insoluble in water, in spirit of wine, and even in alkaline liquors; that their diffusion through these liquids is caused merely by their adhesion to certain gummy and resinous particles; and that they may be disengaged from these gummy and resinous matters, by applying a piece of linn, in which they have a greater adhesive power; and this seems to be the case of the root-coloured and blue dyes; and by applying another substance, to which these particles have a greater power of adhesion, such as the earth of alum, in those dyes where that salt is used, together with some other substance, as fixed or volatile alkali, capable of decomposing alum; or as the ferriuginous earth of the green spirit in black dyes, to which the colorific particles of the galls adhere; where earths are capable of applying themselves, and of adhering to the linn. The separation of the colouring particles from the gummy and resinous matters is possibly facilitated by the addition of acids and neutral salts, which may combine in some measure the vegetable matters, and leave the colorific particles disengaged; by that they may apply themselves to the linn, or to the above mentioned earths. These salts are also useful by lightening certain colours; all acid salts and alum having the property of heightening the red colour of vegetables. The metallic salt used in the fustic dye, consisting of a decoction of cochineal, to which a solution of tin in aqua regia, and some tartar, are added, has the effect of changing the crimson colour of cochineal into a vivid scarlet; and probably has also the other effects of Muri, of affording an earth, namely that of tin, in which the colouring particles may adhere, and in consolidating the vegetable matters, so that they shall leave the colouring particles detached and suspended in the water. The chief difference then between the false and true dyes is, that the colouring particles in the former are applied to fluids, together with some gummy or resinous matter to which they adhere, and are therefore liable to be washed out along with those matters by any liquid capable of dissolving gums or resins; while the colouring particles of the true dyes are applied to fluids, either alone, or adhering to some fine earth, as that of alum, or of tin; and as both the colouring and the earthy particles are insoluble in any liquids, in which they are most apt to be expelled, as water, soap-water, &c. they are capable of resisting the action of these liquids, and are therefore durable. The above conjectures are confirmed by observing, that when the colouring particles of vegetables and animals are dissolved in an alkaline-livium, by means of gummy, resinous, or oily matters, to which they adhere, they may be separated from their adhesive matters by adding alum, the acid of which enters with the alkali of the livium; while the colouring particles apply themselves to the basis or earth of the alum, now disengaged, with which they

form what are called by painters *lavis*; the colouring matter of which is not here soluble in water or spirit of wine; although these liquids are capable of extracting that colouring matter from the animal and vegetable substances which contain it, by the intervention, as above supposed, of some gummy or resinous matter. *Dict. Chim. Eng. ed. 8vo. art. DYEING, note.*

Dyeing, Terebints, or the *Mastic Terebints*, are best reduced under two heads. *Colours*, or those which properly give the colour. And *Non-colours*, used to prepare the fluids for better taking the dye, and to brighten the lustre of the colours.

As to the *colours*, *terebints*, *colours*, we have, 1. *Iron and steel*, 2. *whit*, 3. *black*, 4. *red*, 5. *blue*, 6. *green*, 7. *yellow*, 8. *orange*, 9. *purple*, 10. *violet*, 11. *scarlet*, 12. *crimson*, 13. *pink*, 14. *lavender*, 15. *mauve*, 16. *chamois*, 17. *beige*, 18. *tan*, 19. *umber*, 20. *sienna*, 21. *ochre*, 22. *umber*, 23. *umber*, 24. *umber*, 25. *umber*, 26. *umber*, by leaving it a day or more to steep. As to the alum, in dyeing filks, it is always applied cold, in which state alone it contributes to the brightness of the dye.

The non-colouring ingredients are, certain refringent, or blinding materials, as galls, fustic, alder-bark, punic-granate-peel, walnut-rinds and roots, sapling-bark, and crab-tree-bark. Certain salts, as alum, argal, fait-petre, fait armoiré, pot-alther, lime, and nitre. Liquors, as well water, river water, aqua-vinæ, vinegar, lemon-juice, aqua-fortis, honey, and melasses. Gums, as tragacanth, arabic, mastic, and fanguis draconis. Secretions, or effluvia, as lapp, fullers earth, lusted-out, or gall, Sec. Metals, and Minerals, as steel filings, flappe, and pewter; to which add copperas, vermillion, antimony, litharge, and arsenic. Lastly, bran, wheat-flower, yolks of eggs, leaven, cummin-seed, fennel-seed, fennel, and fennel.

Of the null of these ingredients, some account may be found under those respective articles, in the course of this book; but with regard to their use and effect in dyeing, it will be necessary to consider them more particularly, and to bring them together in one view.

Among the non-colouring dyes, then, from the mineral kingdom come: 1. Copperas, steel filings, flappe, and pewter, (the first found in the troughs of old grind-stones, whereon cloth-makers have been ground) these are used for all true or Spanish blacks, though not for the Flinders blacks. 2. Pewter, dissolved in aqua fortis, used for the new leather or au-wash. 3. Litharge, though not owned or allowed, is used to add weight to dyed filks. 4. Antimony, used chiefly for the same purpose, though it also contains a tincture fulphureous, which, by precipitation, Sec. affords a great variety of colours. 5. Arsenic, used in dyeing crimson, on pretence of giving a lustre. 6. Vermilion, used by linen-dyers, in their yellow and green colours. 7. Alum, much used, though with what intent, is not agreed on; whether to fix the dye, to render water a proper medium to extract the pungent particles of certain hard drugs; or to favour the lapp, which may interfere between the filk and the dye, and hinder their due adhesion; or to incrust the hairs of wool, and hair, filks, that they may better imbibe their colours; or to contribute to the colour itself, as copperas does to galls, in making black, or juice of lemon to cochineal, in carnations, or aqua fortis impregnated with pewter in the blue-dye; or, which seems most probable, to serve as a viniculum between the cloth and the colour, as clammy oil and gum waters do in painting; alum being a substance whose astringent particles, dissolved with hot liquor, will enter the pores of filks, and on which the particles of dyeing drugs will catch; though it may also serve another use, viz. to dry up certain particles which adhere to the colour to be superimposed; to which add, that it may also serve to brighten a colour, by intrinsically the filk to be dyed with its crystals, on which the dye coming to be applied, has a four effect, than if it were applied on a fibrous matter, such as an unaltered cloth. 8. Bran, and bran-water, whole flour consisting the pores of the filk, keeps its fullness, and thus renders the colour laid on it more beautiful; much as woods to be gilded, are first smoothened over with the white colours. 9. Salt-petre, used chiefly in aqua fortis, in the blue-dye, to brighten colours by back-boiling. For which purpose. 10. Argal is more commonly used. 11. Lime, or chalk, used in the working of blue woad.

Non-colouring ingredients of the animal kind are: 1. Honey. 2. Yolk of egg. 3. Ox-gall; though this, and the rest, are only used by a few particular dyers, to favour, promote fermentation, and increase weight. 4. Stale urine, which is a maximum to favour, also to help the fermenting and heating of woad; though it is also used in the blue dye, instead of lime. In reality as it decreases the yellow when with blue and must prevent its fermentation, it is used to spend woad itself; yet it is known, that the urine, or cold and of piffle-groves, with a well-limed piece of liver of a golden colour, it bears with the hot bath-water, as imagined that the bath-water, are not prepared.

To the class of non-colouring ingredients, may also be added water, by dyers called white liquor, which is of two sorts: 1. White water, used in red, and in other colours wanting refringent, as well as in dyeing filks of a soft complexion, as cotton, fustian, and the several species of cotton, &c. as well for blues, and making yellow and greens look rusty. 2. River-water, softer and freer than the former, and dissolving soap better, used in most cases by the dyers, for washing, rinsing, &c. their clothes after dyeing. 3. Liquor absolutely so called, which is a weak liquor of one part bran, and five of water-vinæ, boiled an hour, and put in a leather cistern to settle: but or five days in summer turn it too four,

and render it unfit for use. Its office is to contribute to the building of the colour. It is known, that starch, which is only the float of bran, makes a clinging paste, which will conglomerate paper, though not wool or metals. Accordingly lean liquors are used to mussy dyeing filks, as to madder, which is rendered clammy and glutinous by being boiled in bran water, and thus made to stick the better to the dyed stuff. 4. Gum tragacanth, arabic, mastic, and fanguis draconis, are used in dyeing filk, chiefly to give it a glossiness, which may make it seem finer, stiffer, and to increase its weight. Pasty, oil super.

DYEING, the art of, may be divided into as many branches as there are different colours, to be communicated, and form of different stuffs to be the subjects of it.

DYEING OF CLOTH, SUGAR-DRAUGHT, and other useful Manufactures. With regard to dyeing in cloth and finished pieces, it is begun with a strong decoction of woad and indigo, which gives a deep blue. The dye added for this blue grounds to most the cloth, having already a considerable body of colour, may require less of the backing materials; and consequently be less weakened, than if it was dyed directly from white to black, because, blue is essential to the production of the black dye, for without either a blue ground, or a line superimposed to the violet and galls, no other than browns are obtained. Stuff, whose price will not admit of blue dyes, are dyed by the French and German writers to be grounded with a deep brown, by boiling them with walnut-tree, or walnut-tree roots; but this practice is never followed by our dyers. However it should seem, that any deep colour, which does not hurt the cloth, is preferable to white. After bluing, the filks being boiled with alum and tartar, or pot-alther, are to be madder with common madder. This practice of muddering is one of the regulations for the French dyes, published by the order of M. Colbert. It has not been found, however, on fair trials, to be absolutely necessary, or to contribute any thing either to the beauty or duration of the black. M. Hellet observes, that having dyed a piece of cloth of deep blue, he maddered one half, and dyed both the maddered and unmaddered halves black in one copper; and that the unmaddered half was the best black, without that rusty hor which the other had. The most plausible reason in support of this practice is this, that it prevents the black cloth from staining the skin or linen; but, according to M. Hellet, all that the madder can do in this respect is to diminish the superfluous blue, which is owing not to the madder itself, but to the liquor with alum and tartar preparatory to the madder dye; an advantage which may be obtained by sufficiently knowing the cloth in the boiling mill after the dye. Dr. Lewis adds, that this is evident from the experience cloth dyed by our dyers, among whom the injudicious and misapplied practice of muddering is unknown. They have indeed a colour called madder black, dyed on hair, for exportation to Spain and Portugal, which is a kind of black dye, very durable, without any violet or other preparation of iron, from a combination of blue dye, with the madder red. Cloth is then dyed black with slopp-galls, copperas, and fumach, and finished by back-boiling in woad or log-wood. Logwood is the material which adds blackness to the various shades of brown produced by violet and galls; and this black dye, though not of the most durable kind, is the most common. On blue cloth, a good black may be dyed by violet and galls alone; but even here, an addition of logwood contributes much to improve the colour. A hundred pounds of woollen cloth, dyed first to a deep blue, require for the black dye about five pounds of violet, five of galls, and thirty of logwood. The galls, beaten into moderately fine powder, and tied up in a bag, are boiled for a little time in a copper of water sufficient for working the cloth in. The blue cloth, after being steeped in river water, and drained, is in this state put into the boiling decoction of the galls, and kept turning therein for two hours or more; the bag of galls being now and then squeezed, in order to extract their virtue. The logwood, being sliced or flayed into small chips, or pulverized, is boiled in another copper for several hours; and this liquor is usually prepared a considerable time before it is used, as its colour improves by keeping. When this liquor is made of a scalding heat, the violet is thrown into it, and as soon as it is dissolved, the galled cloth is put in. A boiling heat should never be used after the violet is added to the liquor, because it would augment the corrosive power of the salt, and impair the beauty of the colour, by hastily extracting part of the feruginous matter of the violet in an ochery form, before it can come sufficiently in contact with the astringent substance with which the cloth is impregnated. The cloth is continually turned about in the liquor, and occasionally taken out and aired, which operation con-

tributes to secure the colour. After two hours continuance in the dye, the cloth, having received a good black, is taken out, washed with cold water, and pulled through the fulling-mill. Superfine cloth is fulled three times with warm sapon of soap, by which the superfluous colour is disengaged, and the cloth softened. The cloth is improved neither in beauty nor durability of colour, by being repeatedly passed through the dye liquor, or by increasing the quantity of ingredients still used, after it has once acquired a full black colour. Our dyers use a small quantity of verdigrise for some of the superfine black-cloths; but this is more frequently used by the French. Mr. Helot gives the following process, as the best, and as that, which produces the finest velvet black on cloth, is followed in the best dye-houses in France. For a hundred pounds of blue cloth, ten pounds of logwood chips, and the same quantity of Aleppo galls, in powder, are tied up together in a bag, and boiled in a muddling copper, with a suitable quantity of water, for twelve hours. One-third of this decoction is taken out into another copper, and two pounds of powdered verdigrise added to it. In this mixture, kept gently boiling, or rather scalding hot, the cloth is dipped, and constantly turned for two hours; after which it is taken out and aired. Another third of the decoction is added into the same copper, eight pounds of green vitriol added, and the fire slackened about half an hour. The vitriol being dissolved, the cloth is put in and worked for an hour, and then taken out and aired again. The remaining third of the decoction is then put to the other two, the bag of galls and logwood being well pressed out, fifteen or twenty pounds of fumac are now added; and as soon as the copper begins to boil, two pounds more of vitriol are thrown in with some cold water to slacken the heat. The cloth is kept in for an hour, then taken out and aired, dipped a second time, and kept turning for an hour longer. The cloth, now completely dyed, is washed in a river, and covered in the fulling-mill till the water comes from it colourless. It is then pulled through a copes of wool, which is supposed to soften the cloth and confirm the colour; but it is observed in this process, that the quantities of vitriol and galls may be diminished, and the time of boiling much shortened; and that the weak liquor only supplies the place of soap, and is altogether unnecessary, after covering with soap the liquor remaining after both these processes retains, and will communicate a dilute black, or a grey colour, to as much cloth as can be conveniently worked in it.

As galls are an expensive article in the operation of dyeing, other cheaper astringents have been resorted to as a substitute; so that they have been used in less quantity than in the proportion already stated, and weaker astringents have been taken in larger quantity. In the Swedish Transactions for the year 1773, a fine black is said to be dyed without galls or logwood, by means of a plant called in Sweden, *myra* or *myrtilla*, which Linnaeus has shown, is no other than the *uva ursi*. This plant is gathered in autumn, while the leaves are green, and carefully dried, that they may retain their green colour. A hundred pounds of swollen cloth are directed to be boiled with sixteen pounds of green vitriol, and eight pounds of white earth, for two hours; and the cloth is next day to be rinsed out; then one hundred and fifty pounds of the dried plant, cut a little, are boiled in water for two hours; and when the plant is taken out, a small quantity of madder is added to the liquor. The cloth is put in along with it, and boiled for an hour and a half, or an hour and three quarters, and afterwards rinsed in water. This dyer said to be chiefly used for fine cloth, and to give less brilliancy than the common black. Dr. Lewis pursued these directions with the German, and was both on white and blue cloth, the colour in the former was only a dark brown, as with other astringents, and for finer a tolerably good black. From former other experiments on oak-bark, Dr. Lewis concludes, that it secures the attention of dyers, and that this bark, or the heart of the oak reduced to powder in mill, will be found an astringent of sufficient efficacy, and supply with advantage the place of galls.

It has been generally observed, that cloth is weakened by the black dye, on account of the corrosive quality of the vitriol more than by any other; and the finer the black the more it has been thought to injure the cloth; and therefore the beauty and durability of the cloth have been thought incompatible with one another. But a German writer on dyeing, distinguished by the approbation of the celebrated Stahl, alleges, that the vitriol is corrosive only so far as it is not saturated with galls; and he proposes, in order to determine the quantity of galls sufficient for complete saturation, to mix a decoction of galls and solution of vitriol in different proportions,

and to drop these liquors much diluted on white paper; and the proportions which give the deepest black colour, as those which should be followed by the dyer, and in which the vitriol is made harmless. This proposition, Dr. Lewis thinks, is about equal parts of the one and the other; and as the dyers generally use these proportions, he concludes, that the common black dye cannot hurt the cloth; and this conclusion is further confirmed by the testimony of a judicious dyer, who observes the corrosiveness or perniciosity, often complained of in black cloths, to the damage it has received before being dyed. It is well known, that all colours receive a black dye, though black will not receive any other, whence it happens, that black is the last resource for cloths that have been damaged, or that have had their colour faded, or impaired by different accidents; besides, vitriol is used in greater quantities for some colour than the black; and the aqua fortis employed in scarlets, oranges, &c. is certainly more corrosive. Wool is dyed black in the same manner with cloth, after having been covered by a mixture of this wine, with twice or thrice the quantity of water made scalding hot; in which operation it is said to lose between one-fifth and one-fourth of its weight. Dict. of Commerce. *Hollers Art of Dyeing*, and *Leslie's Comm. Phil. Techn. p. 407, &c.*

It appears by four experiments lately made, that lime-water, though it tends to deepen the colour produced by some astringents and mineral vitriol, by no means adds to the duration of those colours; and that either by immersion or decoction, it entirely destroys the property in logwood of striking black with mineral vitriol, and therefore can be of no service in the black dye, where logwood is a material ingredient. It is also inferred from the same experiments, that slight boiling is preferable to trituration, for the purposes of dyeing, when a durable colour is wanted. Phil. Trans. vol. lxxv. p. 167. Simple grey, which are no other than white cloths dyed nearly in the same manner as black, are obtained only by using a less proportion of the dye, and by continuing the cloth in the liquor for a shorter time.

These simple greys are of a warm white, and are on a previous ground of blue or other colours. There are also a multitude of compound greys and browns, produced from cloth dyed blue, red, yellow, brown, or of colours compounded of these, by darkening them with the black dye. Scarlet is dyed with kermes and cochineal, with which may also be used argemone and arsenic. *Crimson fast* is given with cochineal, mulberry, aqua fortis, sal ammoniac, sublimed, and spirit of wine. *Fire-fast*, purple, amarant, and *pink-fast*, are given with woad, cochineal, indigo, bradecto, horeh, and archil. See ARCHIL, COCHINEAL, CRIMSON, &c. For common red, pure madder is used, without any other ingredients. *Crimson-red*, *crimson-blue*, *flame*, and *pink-crimson*, are dyed according to their several hues, with cochineal, mulberry, without madder or the like. *Crimson-red* is prepared with Roman alum, and finished with cochineal. *Pink-crimson* must be blackened a little with galls and copperas or the like. *Orange-red*, or *yellowish-pink*, *brilliant-red*, and *coloured-pink*, are given with woad and madder, tempered according to their respective shades. *For blue*, the cloth is given with a strong tincture of woad's *brilliant*, with the same liquor, as it weakens in working. *Dark-brown*, *medium*, and *tan-colours*, are given with woad, washed in decoction than for black, with alum and potashes; after which, they are madder higher than black for tan colours, a little cochineal is added. *Pink colours* are given with galls and copperas; some are begun with walnut-tree leaves, and finished with the former; though, to make them more serviceable, they usually dip them in a weak madder and cochineal. Green are begun with woad, and finished with weld. *Pale-green*, *medium-green*, and *palmer-green*, are given with weld only. *Green-colours* of all degrees are first put in green, and taken down again with least, more or less, according to the shade required. *Faintest*, *dark-green*, *mid*, and *common-colours*, are given with weld and madder. *Newest*, or *bright green*, is given with weld, and green-hair, boiled with potashes. Fustic here is added, as a false colour. V. SYDNEY. Dict. de Commerce, ii. p. 1200. See also in *Technique Parisien*, 1755, 12°. Salm. Polytechn. lib. iii. cap. 37. See the several colours with the substances above enumerated in the course of this Dictionary.

DYEING of wool for supply, is performed after the same manner as cloths, excepting blacks, which are only to be washed, and then put in black, as above.

Black wash for cloths and furs, may be begun with walnut-tree root, and walnut-winds, and finished by dipping in a vat of black.

DYEING of silk is begun by boiling it with soap, &c. in which process it loses about one fourth part of its weight;

weight; then scouring and washing them out in soft water, and keeping them in alum-water cold. For *crimson* they scour them a second time before they put them in the cochineal vat.

Red-crimson is dyed with pure cochineal mastic, adding galls, nutmegs, arsenic, and tartar, all put together in a copper of fair water almost boiling; with which the silk is to be boiled an hour and a half; after which it is suffered to stand in the liquor till next day. *Violet-prime* is also given with pure cochineal arsenic, tartar, and galls; but the galls in less proportion than the former. When taken out, it is to be well washed, and put in a vat of indigo. *Common-crimson* is begun like the violet, but finished by back-boiling, if too bright, with copperas, if dark, with a dip in indigo. *Light blues* are given in a bath of indigo. *Deep blues* are begun with archil, and finished with indigo. For *crimson-colours* the silk is first alumed, then washed with a little indigo. *Pale yellows*, after aluming, are dyed in weld alone. *Pale and brown yellows*, after aluming, are washed strongly, then taken down with rocou dissolved with potash. *Pinkish-colours* are begun with rocou, then alumed and dipped in a vat of two or three. *Carmine*, and *rose-colours*, are first alumed, then dipped in brazil. *Common-carmine*, after aluming, is dipped in brazil and brazilotto. *Lead-colours* are given with sulfate, or with weld, brazilotto, galls, and copperas; but the galls, on these and other occasions, are not to be overused, which increases the weight to the damage of the purchaser; for which reason, it is punished in France as a fraud; and in reality few but black silks need galls.

Black silk of the carter sort, are begun by scouring them with soap, as for other colours; which done, they are washed out, wrung, and boiled an hour in cold galls, where they are left to stand an hour or two; after which, they are washed again with fair water, wrung, and put in another vat of new and fine galls; then washed and wrung again, and finished in a vat of black. *Blue black silks* are only put once into galls, viz. the new and fine sort, which has only boiled an hour; then they are washed, and wrung out, and dipped three in black, to be afterwards brought down by back-boiling with soap. *Sivar. lib. etc. p. 1603. seq.*

M. Macquer, in his Dissertation on the Art of Dyeing Silk, has given the following process for dyeing black, which is followed in the manufactures of Tours and Gènes: the silk, washed with soap, is steeped in a decoction of one-third its weight of Aleppo or blue galls, or half its weight of the weaker white galls of Sicily and Romania, and afterwards washed with water: every twelve ounces are reduced by the cleansing to nine, which ought to be increased by the galling to eleven, and no more. The dyeing liquor, for one hundred pounds of silk, is prepared by boiling twenty pounds of galls in about one hundred and twenty-five gallons of water, and adding to this decoction, after being settled and drawn off from the sediment, two and a half pounds of English vitriol, twelve of iron-sulphate, and twenty of the gum of the cherry or plum-tree; that the gum may dissolve the more readily, it is put into a large copper colander, immersed in the hot liquor, and stirred from time to time with a wooden rod till it is all passed through. This mixture is kept for six or seven days or more, a circumstance supposed to be necessary to its perfection; and being then made as hot as the hand can bear, fresh parcels of the galled silk are dipped in it successively, and kept in about ten minutes each; and all of them, after being sized, are dipped over again, several times, with the addition of more vitriol and iron-sulphate till they have acquired the requisite blackness, after which they are well washed in water. Dr. Lewis observes, on this process, that while five or six pounds of galls are sufficient for one hundred pounds of wool, upwards of fifty pounds of galls are here allowed to the same quantity of silk; and that logwood, an essential ingredient in the black dye on white woollen, is not at all required for silk. He also found, in repeating this process with a less quantity of the several ingredients, but in the same proportion, that by adding more and more of the vitriol, so that the whole amounted to one-fifth of the weight of the silk, and repeating the dipping thirty times or more, he obtained at last a good black; nor did he observe any difference in two blacks produced by repeating the operation with and without any iron filings: he apprehends likewise that the gum is rather of disservice, than advantage. Dr. Lewis concludes upon the whole, that a good black may be dyed on silk, with the same materials, in the same method, and with the same dispatch, as on wool and woollen cloth. *Com. Phil. Techn. p. 425, &c.*

Dyeing of thread is begun by scouring it in a ley of good ashes; after which, it is wrung, rinsed out in river wa-

ter, and wrung again. For a *bright blue*, it is given with brazilotto and indigo. *Bright green* is first dyed blue, then back-boiled with brazilotto, and wringer, and finally wooded. For a *dark green*, it is given like the former, only darkening more before wooing. *Lemon, or pale yellow*, is given with weld, mixed with rocou. *Orange and yellow*, with sulfate, weld, and rocou. *Red, both bright and dark*, with *sumac-leaf*, &c. are given with brazil, either alone, or with a mixture of rocou. *Pale, dry rose, and rose-quin*, are given with brazil, taken down with indigo. *Pinkish and rose-colours* are given with galls and copperas, taken down with weld, rocou, or sulfate. *Black* is given with galls and copperas, taken down and finished with brazilotto wood.

It is observable, that the black vitriolic dye, which is very durable on the substances already mentioned, is pendable on linen and cotton. Pieces of both sorts of cloth and cloths of thread boiled first with galls, and afterwards infused and dipped repeatedly in a decoction of logwood with vitriol, received a good black colour, which was in some measure discharged by washing with soap; another black dye proved equally profitable, though the linen was steeped for a month previous to the dye, with galls and with oak-bark. The dyes of thread obtain a colour somewhat more lasting, by steeping it first in alum-water for several days; and then dipping it repeatedly in the dyeing liquor, cold, or only lukewarm. This liquor consists of the iron and astringent matters mixed together, and in the room of, or along with vitriol, they use either filings of iron or slips. Dr. Lewis made several unsuccessful trials to fix the black dye in linen and cotton. He has given us, from the dissertation of M. l'Abbé Mazarin, on the red printed cottons of the East Indies, an account of a method practised by the Indians, of impregnating their cotton with animal matter, in order to its receiving a red stain. A ley is made from the ashes of a certain kind of woody, and with this is mixed some sheep's dung, and a quantity of the oil of fetum, in want of which oil they use hog's lard: these ingredients stirred together are said to unite into a milky liquid. The cotton is steeped in this liquor during the night, and exposed to the hottest sun during the day for a fortnight. He applied a similar preparation to the black dye; but the result was not such a degree of success as to render the process interesting to the workman. He observes, on the credit of a skilful artist, that some printed linens and cottons have a durable black stain, which is made with madder and a solution of iron. For this purpose a quantity of iron is put into four flagon beer; and to promote the dissolution of the metal, the whole is occasionally well stirred, the liquor at times drawn off, the ralt beaten from the iron, and the liquor poured on again; the solution is not fit for use in less than a twelve-month. This solution stains linen yellow, and of different shades of buff colour, and is the only known material by which these colours can be fixed on linen. The cloth, stained deep with the iron liquor, being afterwards boiled with madder, without any other addition, becomes of the dark colour which is seen on printed linens and cottons; which, though not a perfect black, bears a very near resemblance to it. He apprehends, that a better black might thus be dyed on thread, than that which the printer on linen produces; because in this last business, while some parts of the linen are stained deep with the iron liquor, in order to their being made black, others are stained pale, with the same liquor diluted with water, for making purple; and others, designed to be red, are prepared with a solution of alum and sugar of lead; all these colours are dyed in the same copper of madder, with a heat a little below boiling; but a boiling heat, which would injure the red colours, would deepen the black, and might be advantageously applied, if thread, or whole pieces of linen or cotton, were to be dyed of this colour. *Com. Phil. Techn. p. 429, &c.*

Dyeing of hats, is done by boiling a hundred pounds of logwood, twelve pounds of gum, and six pounds of galls, in a proper quantity of water for some hours; after which about six pounds of verdigris, and ten pounds of green vitriol are added, and the liquor kept simmering, or of a heat a little below boiling. Ten or twelve dozen of hats are immediately put in, each on its block, and kept down by cross bars for about an hour and a half; they are then taken out and aired, and the same number of others put in their room; the two sets of hats are then dipped and aired alternately, eight times each; the liquor being refreshed each time with more of the ingredients, but in less quantity than at first. This process affords a very good black on woollen and silk stuffs as well as on hats. *Com. Phil. Techn. p. 428. See Hat.*

Dyes, Proof. There are divers ways of proving the truth of *dyes*, or examining the justness and legitimacy of their composition. To discover whether a cloth have been duly treated by the dyer, and the proper foundation laid, a white spot, by the French called *refta*, of the bigness of a shilling, ought to be left; besides a white stripe between the cloth and the silk.

Farther proof is had by boiling the dyed stuff in water with other ingredients different according to the quality of the dye to be proved. If the colour sustain the test, i. e. do not discharge at all, or very little, so that the water is not discoloured by it, the dye is pronounced good: otherwise it is false.

Some colours will for a long time resist the injuries of the air; and these are therefore called the good or standing colours; and there are others, which the bare exposure to the air will destroy or deface in a very little time; these are therefore called the false or fading colours. In what manner is the action of the air upon these last to be explained? Does it take away, or carry off from the stuff the particles of the colours; or does it only break and destroy that beautiful and regular texture of each particle on which the colour depends? The dyers very often have recourse to several ingredients, in order to produce one colour; and reason seems to urge, that one of these false or fading colours might be rendered lasting by mixing it with a permanent one: the dyers are also of this opinion. But it is nevertheless an erroneous one; for repeated experiments have proved, that one of these false colours fades as soon, when it is mixed with a standing or lasting colour, as when it is used alone. There are but few colours on which this experiment can be tried, so as to come to a regular decision. One of the principal is the mixing of a blue and a yellow, for producing a green. In this experiment, if the blue and the yellow be both standing or permanent colours, the stuff will perfectly hold its colours, and succeed alike, whether it be dyed first blue, and afterwards yellow; or first yellow, and afterwards blue. But if one of the two colours be a false or fading colour, it is found that the green produced by the mixture, will not stand, though the other be ever so good or permanent a colour.

There is a shorter way of trying the permanence of many colours of this kind than that of exposing them to the air, since in boiling only five minutes in a pint of water, in which there is dissolved half an ounce of alum, they will lose as much colour as they would have done by being exposed two days to the air in summer. Some colours acquire different methods of trial, but this serves for almost all. The shades of blue, yellow, red and green, purple and green, are the finest colours to experiment these things upon, as the same previous preparation or impregnation of the stuff serves for both, and both depend upon blue for their basis, the purple being made of blue and red, and the green of blue and yellow.

It should not seem surprising, if the stuff be first dipped into a dye of a standing blue, and afterwards into a fading red or yellow, to turn it green or purple, that the action of the air, or boiling in alum water, should carry off those false colours, which had only been applied to the stuff after it was before saturated with a standing colour. But it might be expected, that when the stuff was first impregnated with them, and afterwards had the blue added upon them, that either the blue must be the colour that went off, or that they must all remain. But in effect, nothing of this difference is found, but the blue remains, while the fading colours go off, however or in whatever manner or order they are applied. *Mem. Acad. Scienc. Par. 1737.*

Dyes of Silk, Proof of the. For red crimson, the proof is made by boiling the silk with an equal weight of alum. For scarlet crimson, it is boiled with soap almost of the weight of the silk. For violet crimson, with alum of equal weight with the silk, or with citron juice, about a pint to a pound of silk. These ingredients are to be mixed, and put in fair water when it begins to boil; after which the silks are also to be put in; and after boiling the whole for half a quarter of an hour, if the dye be false, the liquor of the red crimson will be violet, in case it has been dyed with archil; or very red, if with brazil. That of crimson scarlet, if rocou hath been used, will become of an aurora colour; or, if brazil hath been used, red. On the contrary, if the three sorts of crimson be truly dyed, their liquors will discover very little alteration.

A still surer way to discover whether crimson silks have been rightly dyed, is by boiling a piece of standard dyed silk, kept for that purpose at Dyers-hall, after the same manner, and then comparing the tinctures of the two liquors.

To discover whether other colours have been dyed with galls, the silk is to be put in fair boiling water, with potash, or soap, nearly of the weight of the silk; after some time, it is taken out; upon which, if it hath been dyed with galls, the colour will be all vanished, and nothing but that of the galls left, which is a sort of seal-moort, or wood-colour.

The dyeing of silk with galls may also be detected by putting it in boiling water, with a gallon of citron juice; being taken out, and washed in cold water, and then dipped in a black dye, if galls have been used, it will turn black; if not, it will be of a brown-bread colour.

To discover whether black silk has been over-dyed with galls, steel-silings, or fluffs, it is boiled in fair water with twice its weight of soap: if it be laden with galls, it will turn reddish, otherwise it will keep its colour.

Dyes of Cloths, Proof of the. To discover whether black cloth has been first woaded, and maddered; a sample of it, and at the same time, a sample of standard black kept for that purpose by the Dyers company, is to be taken; and then as much Roman alum as is equal in weight to both, together with a like weight of potash, is to be put over the fire in a pan of bean-water; when it begins to boil, the two samples are to be put in; and after half an hour to be taken out and compared. The piece which has only been woaded will be found bluish, with somewhat of a dull green; if it hath been both woaded and maddered, it will be of a tan, or minim colour; and if it has been neither woaded nor maddered, its colour will be dunnish, between yellow and fallow.

The same discovery may be made by steeping a small bit of the black cloth for a day or two in water acidulated with oil of vitriol; or by boiling it about a quarter of an hour in a solution of alum and tartar, made by the proportion of one ounce of each, to a pint of water. If the cloth has had a previous blue ground, it will be of a bluish black colour; but if it has been dyed straight to white, it will look of a muddy reddish brown. The dyers commonly leave some blue marks at the end of pieces of black cloth, by fixing pieces of lead on them, in order to show that the piece has been regularly dyed in a blue ground, and that the colour is durable.

For cloths dyed of a minim colour, the proof is to be made after the same manner as that of blacks.

To know whether scarlet or crimson cloth hath been dyed with pure cochineal, they are to be boiled with an ounce of alum to a pound of cloth.

For cloths of other colours, the proof is to be made in the same manner as that of blacks and minims. *Savar. lib. cit. p. 1655, seqq. voc. Depouill.*

DYING, the Laws relating to, are as follow. Dyers shall dye both the cloth and the silk, or forfeit it. 1 R. III. cap. 4. No dyer may dye any cloth with archil, or with brazil, to make a false colour in cloth or wool, &c. on pain of twenty shillings. Stat. 3 & 4 Edw. VI. cap. 2. Dyers are to fix a seal of lead to cloths, with the letter M, to show that they are well maddered, &c. or forfeit three shillings and four pence; and not to use logwood in dyeing, on pain of forfeiting twenty pounds. Stat. 23 Eliz. cap. 9. And penalties are inflicted on dyers, who dye any cloths deceitfully, and not being dyed throughout with wood, indigo, and madder; also marks shall be put to the cloth dyed, &c. Dyers in London are subject to the inspection of the Dyers company, who may appoint searchers; and out of their limits, justices of peace in sessions to appoint them: opposing the searchers incurs ten pounds penalty, by Stat. 13 Geo. I. c. 24.

DYING, in a more extensive sense, is applied to all kinds of colourings given to bodies of any sort.

In which sense, *dying* amounts to the same with *coloration*; and includes staining, painting, gilding, marbling, printing, &c. The Chinese are said to practise the *dying* of tea with catechu, which gives the worst sorts of green tea-leaf the colour, and its infusion the tincture of bohea. *Short. Diss. on Tea, pref. p. 15. See TEA and CATECHU.*

The sorts of *dying* now commonly used in vulgar trades, are, 1. Whitening of wax, and several sorts of linen, and cotton cloths, by the sun, air, and reciprocal effusions of water. See BLEACHING. 2. Staining of wood and leather by lime, salt, and liquors, as in staves, canes, marble, leathers, marquetry, &c. 3. Marbling of paper, by tempering the colours with ox-gall, and applying them upon a stiff gummed liquor. See PAPER. 4. Colouring, or rather discolouring silks, tiffanies, &c. by brimstone. 5. Colouring several iron and copper-works into black with oil. 6. Giving leather a gold colour, or rather *dying* silver-leaves like gold, by varnishes; and in other cases by urine and sulphur. 7. Staining of marble and

and alabaster, with heat, and coloured oils. 8. Tinging silver into brass with brimstone or urine. 9. Colouring the barrels and locks of guns blue and purple with the temper of small-coal heat. 10. Colouring glass crystals, and earthen-ware, with the ruffs and solutions of metals. See POTTERY, &c. 11. Colouring live hair, as in Poland, both horse and man's hair, and also of fur. 12. Enamelling and annealing. See ENAMELLING. 13. Application of colour, as in the printing of books and pictures, and in the making of playing-cards, jappanning, &c. See PRINTING, CARDS, and JAPPANNING. 14. Gilding and tinning with mercury, block-tin, and fal armoniac. See GILDING and TINNING. 15. Colouring metals, as copper with calamine into brass, and with zinc or filipetre into false gold, or into false silver with arsenic. See CALAMINE, BRASS, ZINC, ARSENIC, &c. 16. Making painters colours, by preparing of earth, chalk, and fat, as in umbers, ochre, Cologn earth, &c. out of the calces of lead, as ceruss and minium; by sublimate of mercury and brimstone, as in vermilion; by tinging of white earths variously, as in vermillion, and some of the lakes; by concrete juices or facins, as in indigo, pinks, lap-green, and lakes; and by ruffs, as in verdigrise, &c. See CERUSS, MINIMUM, VERMILION, INDIGO, &c. 17. The applying of these colours by the adhesion of ox-gall, as in the marbled paper above said; or by gumm-water, as in flouting; or clumny-drying oils, as the salt of linseed, nut, spike, turpentine, &c. See PAINTING, LIMING, &c. 18. Watering of tabbies. See WATERING. CALENDAR, TARRY, &c. Petty Appa. Hift. of Dying, ap. Spurr.

Color dyed is the common matter of artificial jewels: the tinctures are given with zaffer, manganese, ferreto, ciocus maris, &c. The processes are described at length in Antonio Neri, de Re Vitraria, lib. i. cap. 12, 13, 14, 15, &c. See GLASS, GEM, &c.

The Persian women, when grown old, dye their grey hair black by a very unoward operation, viz. holding

vac head some hours with the hair fopped in a boiling

tincture of the root of a tree called *cachou*, by the Spaniards

magur.

DYING of leather, skins, &c. A black colour is easily given to tanned leather, by rubbing it over three or four times with a solution of vitriol, or with a solution of iron in the vegetable acids. For leathers that have not been tanned, some galls or other astringents are added to the solution of iron; and in many cases, particularly for the finer parts of leather, and for renewing the blackness, ivory or lamp-black are used. See CORRUPTING. A blue colour is given by steeping the subject a day in urine and indigo, then boiling it with alum; or it may be given by tempering the indigo with red wine, and washing the skins therewith. Red is given by washing the skins, and laying them two hours in galls; then wringing them out; dipping them in a liquor made with liguflrum, alum, and verdigrise in water; and lastly, in a dye made of brazil wood boiled with lye. Purple is given by wetting the skins with a solution of rock alum in warm water, and when dry again, rubbing them with the hand with a decoction of logwood in cold water. Green is given by fuccating the skin with fip-green and alum-water boiled; to darken the colour, a little more indigo may be added. Dark green is also given with steel-blings, and fal armoniac steeped in urine till soft, then smeared over the skin; which is to be dried in the shade. Sky-blue, is given with indigo steeped in boiling water, and the next morning warmed and smeared over the skin. Yellow is given by fuccating the skin over with aloes and linseed oil dissolved and strained; or by infusing it in weld. Orange-colour, is given by fuccating with fultic berries boiled in alum-water; or for a deep orange, with turmeric. Salm. Polyg. lib. iii. cap. 34. p. 272.

The following proceeds for dyeing leather red and yellow, as practised in the East, for that kind called Turkey leather, were lately communicated, by Mr. Philips, a native of Armenia, to the Society of Arts, &c. The skins are prepared for both dyes, by dressing them in lime. For this purpose, after having been dried with the hair on, they are first laid to soak in clean water for three days; they are then broken over the flesh side, put into fresh water for two days longer, and afterwards hung up to drain half an hour. They are then broken again on the flesh side, limed with cold lime on the same side, and doubled together with the grain side outward. In this state, they are hung up within doors for five or six days, till the lime be loose, which is then taken off; and the skins are returned into the lime pit for about three weeks. They are then taken out and well worked, flesh and grain, every sixth or seventh day during that time; after which they are washed ten times in clean water, and the water is changed at each washing. The next

operation is drenching: in order to which, a liquor is prepared, by mixing bran and water, and new milk, warm, allowing about three pounds of bran for five skins, and about a gallon of water to each pound of bran: the skins are left to lie in this drench three days, when they must be well worked, and returned into it for two days longer. They are then taken out and rubbed between the hands; the water is squeezed from them, and the bran scraped off clean from both sides; after which they are washed ten times in clean water, and the water squeezed out of them. The skins that are to be dyed red are then prepared by honey and burnt in the following manner: a pound of honey is dissolved in three pints of lukewarm water; to which are added two double handfuls of bran; and then four skins are well worked in this quantity of mixture, one after another. They are then folded separately in a round form, with the flesh side outward, and laid in an earthen pan, or other proper vessel, by the side of each other in summer, and upon each other in winter; and the vessel is placed sloping, so that the liquor may drain from them. In this operation the liquor will ferment, and the skins swell; in which state they remain about seven or eight days, the liquor that drains from them being poured off at occasion requires. On the eighth or ninth day, they are taken out of this mixture, and rubbed with dry common sea-salt, in the proportion of about half a pound to each skin, by which they are contracted, and the remaining moisture is to be squeezed out, by drawing each skin separately through the hands. They are then scraped clean on both sides from the bran and superfluous salt and moisture; and fresh salt is thrown over the grain side, and well rubbed in with the hands. They are now doubled, with the flesh side outward, lengthwise, from tail to tail, and more salt is thinly strewed over the flesh side and rubbed in. About one pound and a half of salt for each skin will suffice for both these operations. In this state they are folded on each other, and laid between two clean boards, under a heavy weight, and continued in this pressing state for two days or more, when they will be fit for dyeing. The red dye is prepared by boiling seven ounces of thecan, tied up in a linen bag, in eight gallons of water for about an hour; and by putting into the boiling mixture two drams of pomegranate bark, three-fourths of an ounce of turmeric, three ounces of cochineal, and two ounces of loaf sugar, and letting the mixture afterwards boil for six minutes: this is the proportion for four skins. N. B. The thecan is easily to be obtained from any of the ports in the Levant: it is the eastern jointed kati, called by botanists *foliaria*, but different from the small species met with on the English sea-coast. Two pints of the above liquor are to be measured out in a flat earthen pan; and when it is as cool as new milk, one skin folded lengthwise, with the grain side outward, is to be dipped in it, and rubbed gently with the hand; then it is hung up to drain; and the superfluous dye is thrown away. The same process must be observed with respect to the other three skins; and the same operation must be repeated on each skin separately eight times before each flesh dipping; then let the skins be squeezed and laid in a dipping-pen to drain for about two hours, or till they are cold. They are next to be tanned, by working them well for half an hour or more in a mixture, made by powdering four pounds of the best white galls in a marble mortar, fitting and mixing them with about three quarts of water: the skins are folded in four folds, and left to lie in the fun twenty-four hours; after which they are again to be worked, scraped clean from the first galls, and put into the like quantity of fresh galls and water: they must be well worked in this for three quarters of an hour, folded up as before, and left in it three days. On the fourth day they must be washed clean from the galls in seven or eight fresh quantities of water, and hung up to dry. When they are almost dry, they are to be scraped on the flesh side with the scraper, in order to reduce them to a proper thickness; they are then to be laid on a smooth board, and glazed, by rubbing them with a smooth glass. Afterwards they must be oiled, by rubbing them with olive oil, in the proportion of one ounce and a half of oil to four skins, and then grained on a graining board lengthwise, breadthwise, and crosswise, from corner to corner.

The skins that are designed for the yellow dye, after having been drenched, must be well worked for half an hour or more, in a mixture of one pound and a half of the best white galls, powdered with two quarts of clean water: this is the proportion for four skins. They must then be separately doubled lengthwise, rolled up with the flesh side outward, laid in the mixture, and close pressed on each other; in which state they are to remain

two whole days. On the third day they must be again well worked in the fat, and afterwards scraped clean from the galls with an ivory or brass instrument; and then put into a strath tan made of two pounds of galls, with about three quarts of water, and well worked in it fifteen times. After this they must be doubled, rolled up as before, and remain in the second tan for two days. On the third day, a quarter of a pound of white sea-salt must be worked into each skin, and the skins be doubled and rolled, and laid in the tan till the following day, when they are to be washed six times in cold water, and four times in lukewarm water. The skins must then be well pressed between two boards, and drained.

The yellow dye, for which they are now ready, must be prepared by mixing fix ounces of cassia gelsina, or the berries of an eastern rhumus, or buck thorn-tree, with the same quantity of alum; these are to be pounded together in a marble or brass mortar, with a brass pestle: this is the proper quantity for four skins. The berries may be obtained at Aleppo, or other parts of the Levant; or the Avignon berries, though they yield a weaker dye, may be substituted in their room. The powdered materials may be divided into three equal parts, and one of these parts is to be stirred in about a pint and a half of hot water, in a china or earthen vessel. When the liquor has been boiled and stood to cool, so as not to scald the hand, a fourth part of it is poured on the grain side of one of the skins laid flat on a table in a warm room, with this side uppermost, and well rubbed over the skin. The same process is to be pursued with the other three skins. The same operation must be repeated twice more, separately on each skin, with the remaining eight ounces of the pulverised berries and alum, mixed with the same proportion of hot water. When the skins are dyed, they are to be hung up loosely, with the grain side outwards, for about three quarters of an hour to drain, and then well washed six times or more in running water. They must then be pressed for about an hour, till the water is well squeezed out, and hung to dry in a warm room. And lastly, they must be dyed and grafted, in the manner already prescribed for these dyed red, except that they must not be oiled. *Doffie's Memoir of Agriculture*, vol. i. p. 400, &c.

DYEING is staining of wood, for staining, staining, &c. *Red*, is done by boiling the wood in water and alum; then taking it out, adding brazil to the liquor; and giving the wood another boil in it. *Black*, by brushing it over with logwood boiled in vinegar; but then washing it over with a decoction of galls and copperas till it be of the hue required. *Any other colour* may be given by squeezing out the moisture of horse-dung through a sieve, mixing it with dissolved rock alum and gum arabic; and to the whole adding green, blue, or any other colour designed. After standing two or three days, pear-tree, or other wood, cut to the thickness of half a crown, is put into the liquor boiling hot, and suffered to remain till it be sufficiently coloured. *Park. Treat. of Japan*, cap. xxvii. p. 82.

DYEING of bone, horn, or ivory. *Black* is performed by steeping brass in aqua fortis till it be turned green; with this the bone, &c. is to be washed once or twice; and then put in a decoction of logwood and water, warm. *Green*, is begun by boiling the bone, &c. in alum water; then with verdigrise, sal ammoniac, and white-wine vinegar; keeping it hot therein till sufficiently green. *Red*, is begun with boiling it in alum-water, and finished by decoction in a liquor compounded of quicklime steeped in rain water, strained, and to every pint an ounce of brazil wood added: the bone, &c. to be boiled herein till sufficiently red. Other methods are given by Salmon. And from him by Houghton. *Park. Lib. cit.* p. 82. *Salmon Polygraph*, lib. iii. cap. 75. p. 275. *Hought. Collect.* N° 128, tom. i. p. 361. See **BONES**, **HORN**, **IVORY**, &c. The refuse of the bow-dye given to horns to feed on, is said to tinge their very bones red.

DYEING of marble and stones. See **STAINING**.

DYKE, *Reeve*, a ballist, or officer, that has the care and oversight of the dykes and drains in deepening fens, &c. We find mention made of this officer anno 16 & 17 Car. II. cap. 11. See **DIRE**.

DYNA, in *Commerce*, a kind of East Indian coin, worth about thirty fillings of English money.

DYNAMICS, from *δυναμις*, power, is the science of moving powers; more particularly of the motion of bodies which mutually act on one another. See **MECHANICS**, **MOTION**, **COMMUNICATION** of Motion, **OSCILLATION**, **PERCUSSION**, &c.

DYNASTY, a term in *History*, signifying a race or succession of kings of the same line, or family. The word is formed from the Greek *δυναστος*, of *δυνασσειν*, to be powerful, to be king.

We find frequent mention in ancient history of *dynasties* of Persians, Assyrians, Medes, &c. The ancient Chronicon of Egypt mentioned by Syncellus, gives us an account of three different *dynasties*: that of the gods, that of the demi-gods or heroes, and that of men or kings. The two former are prefaced as continuing thirty-four thousand two hundred and thirty-one years, in order to favour the high antiquity of the Egyptians: the last, as commencing with the reign of Menes the first king of Egypt, and terminating with Nectanebus II. under whom the kingdom was conquered by Artaxerxes Ochus; and this is said to have lasted two thousand three hundred and twenty-four years. Manetho has left us an historical chronology of Egypt, divided into thirty *dynasties*, comprehending a space of more than five thousand three hundred years to the reign of Alexander; but it is certain that these were collateral and not successive.

DYOTA, in *Chemistry*, from *δυω*, double, and *οτα*, ear, a peisan, or circulating vessel with two ears, in shape resembling a man standing with his arms bent outwards, and with his hands on his sides.

DYPTYCHA, or rather **DIPTYCHA**. See **DIPTYCHA**. **DYSIA**, in *Mythology*, inferior goddesses among the Saxons, being the messengers of the great Woden, whose province it was to convey the souls of such as died in battle to his abode; called *Falldis*, i. e. the hall of slaughter; where they were to drink with him and their other gods, *ceresias*, or a kind of malt liquor, in the skulls of their enemies. The *Dysie* conveyed those who died a natural death, to *Hela*, the goddess of hell, where they were tormented with hunger, thirst, and every kind of evil.

DYSGRASY, from *δυσ* and *γραφειν*, an ill-temperament or habit of the blood and humours, as in a jaundice or the like.

DYSENTERY, *Dysenteria*, in *Medicine*, a bloody diarrhoea; or a flux of blood by stool, attended with pains and griping. *Dr. Akensted* calls this disease a rheumatism of the bowels.

The word *dysentery* is formed from the Greek, *δυσ*, difficulty, and *εντερν*, intestine; and properly signifies that kind of flux of the belly, characterized by the frequency of stools, or ejections, mixed with blood, and accompanied with gripes. The fever, ulcers, &c. which attend it, are not essential to the disease; though many both of the ancients and moderns, think the latter are.

The *dysentery*, Sydenham observes, begins with a chilliness and shivering; which is followed by a heat: then gripings of the belly ensue, with mucous, or fanious stools, which in progress of time are found interspersed with streaks of blood, and attended with vehement pain.

The stools are sometimes void of blood; and yet if they be frequent, and attended with gripes, and a mucous colic, the same author says it is a proper *dysentery*.

Along with the excrements, besides a whitish mucosity, frequently there come scrapings of the guts in form of little skins. If pure blood be evacuated, the patient's life is in great danger. Vomiting and hiccupping are also had signs, because they indicate an inflammation of the stomach. A feeble pulse, colicness of the extremities, with difficulty of swallowing, and convulsions, are signs of approaching death.

Kræmmer makes three kinds of *dysenteria*. 1. When a landmark blood is evacuated, from a mere plethora, or plenitude, without any disorder of the intestines; as in the hæmorrhoidal flux.

2. When a thin watery blood is evacuated, called the *hypocritic flux*, though really arising from the hæmorrhoidal vessels.

The third kind, which is that we more peculiarly call *dysentery*, is, when blood is cast out mixed with a purulent matter in the excrement. See **FLUX**.

This is either benign, i. e. without a fever, and not contagious; or malignant, which is attended with a pestilential fever, and frequently ravages whole cities and provinces; happening most commonly in armies. In the last stage a sort of caruncles are frequently ejected along with the purulent matter, which are difficult to be accounted for, unless from an excoriation and ulceration of the intestines. Sometimes the intestines in this case are even gangrened.

The cause of the *dysentery*, as assigned by some physicians, is a ferous, or other morbid humour mixed with the mafs of blood; the consequence of which is a too great fermentation in the blood, and a dissolution of its parts, which are rendered too liquid. The second cause is a vellication and irritation of the nervous fibres of the intestines, occasioned by sharp acid humours separated from

from the blood, which occasion the spiral fibres that produce the peristaltic motion of the guts to move too fast and thus to expel the matters too hastily out of the intestines. The medicine cause, in the physicians language, is some foreign body adhering strongly to the intestines; and, by its sharp points, wounding the nervous fibres of the intestines, and at length ulcerating them. The remote causes are any thing that corrupts the mass of blood, as viscid and crude sharp juices; ill foods, autumnal fruits, grapes, new wine drank in excess, poisons, violent medicines, waters that have corroded leaden pipes; rainy weather in the spring, with a dry winter, and a hot summer and autumn.

The dysentery is owing to causes little different from those which produce the bilious or putrid fever. Accordingly it is agreed on all hands, that it chiefly proceeds from two causes, different in appearance, but in effect the same, one from acrimony generated within the body; and the other from foul steams, which being received into it, act as a ferment, and suddenly produce the same disorder that arises more slowly from an internal cause.

As to the acrimony, it appears to be of the putrid kind, the dysentery being most frequent in hot, close, and moist seasons, when bodies are most subject to putrefaction; and besides, it prevails chiefly among those of a febrile habit, or the mean and peevish people, who, from foul air, bad diet, and malice, are most liable to putrid diseases.

There is likewise an old observation, that such seasons as produce most flies, cataputaries, and other insects (the increase whereof depends so much upon heat, moisture, and consequently upon corruption) have likewise been the most productive of dysenteries.

Lastly, it is beyond dispute, that the infection is communicated by putrid exhalations from the bodies; but more especially the feces of those who are ill of the distemper. See PRINGLE, Observations on the Diseases of the Army, p. 224, 109.

This disease is the same in camps as in other places; its greater fatality in the former, arising more from want of necessities than from any extraordinary virulence in the dysentery itself.

The seat of the disease is in the intestines, either the large or the small, or both. When the disease is in the small ones, the gripes begin long before the stools, and are felt about the navel; and the blood and excrements are more blended, as being longer together. When the large intestines are seized, the pain is less vehement, and is felt lower, &c.

Physicians distinguish three states of the dysentery, the first, when recent; the second, when it has continued some time, and has much impaired the strength, weakened the tone of the intestines, and abraded their villous coats; and the third, when, either from the putrid fumes within, or the foul air of an hospital, a malignant fever is joined, and a mortification threatened.

In the first stage bleeding is proper, though not in the subsequent ones; also vomiting with ipecacuanha, in small quantities, and repeated several times. Vitrum ceratum antimoni is also recommended as the most efficacious remedy for relieving the stomach and bowels, provided it be given in the beginning of the distemper. After vomiting, a purge of rhubarb, to which are added a few grains of salt of wormwood, may be given. In winter, indeed, and venal fluxes, bleeding and rhubarb have been found sufficient, without vomits. In regard to diet the common practice is to confine the patient in the beginning to rice-gruel, panada, mutton-broth, and the like; and for drink, rice or barley-water, or the white decoction, are recommended. In the convalescent state, they may be allowed meat, but no small beer; and never any milk unless diluted with lime-water. PRINGLE, Observations on the Diseases of the Army, p. 230, 109.

In the second stage, the same diet, with small doses of the bark, to which has been added the extract of logwood, or the tincture of *Tuponia*, is recommended. The following electary, prepared with the *Tuponic* confection, two ounces; Lacerelli's balsam, one ounce; powdered rhubarb, half an ounce; and syrup of marsh-mallows, may be given in the quantity of a nutmeg, twice or thrice a day, as the symptoms may require.

In a putrid dysentery, the patient may be allowed to eat freely of most kinds of good ripe fruit, apples, grapes, currants, strawberries, &c. these being excellently calculated to counteract putrefaction; and with the same intention fixed air, administered both by way of drink and elixer, may be highly useful. They also may be taken both ways; and camomile tea is also an exceeding proper drink, both for strengthening the stomach, and by its antiseptic qualities preventing a mortification of the bowels.

The dysentery, after a seeming cure, is apt to recur upon

any cold, or error in diet; however it is to be observed, that for the most part, relapses are not attended with such acrimony as at first. When relapses are apprehended, or the cure imperfect, the patient must still use a soft mucilaginous diet, and continue to take some mild astringent; which last intention may be answered by lime-water, given to a pint a day, and softened with half that quantity of boiled milk. Sometimes small doses of the bark have been no less effectual. LL. 181d.

Gripes always attend the dysentery, and are relieved by opiates, by fomenting the belly, and drinking camomile-tea; for carminatives, in this case, instead of mitigating, increase the pains. The tea produces this effect not only by its antispasmodic but antiseptic virtue. The fomentations, which are made of herbs, adding some spirits, must be frequently repeated; and when these are found insufficient, the pains may be relieved with a blister, or only a warm plaster, with a fourth or fifth part of the *emplastrum opifolium* added to it.

As to the third stage of this distemper, it coincides with the malignity of hospital fever, See H. 1712, 1713, 1714. Purgatives have rarely any good effect in dysentery; as increasing the fermentation of the blood, and irritating the fibres of the intestines more and more. Nor are emetics in general much better, as tending to draw the peccant humours into the stomach; or at least into the higher intestines, and thus cause more frequent stools. Ipecacuanha, however, is excellent on this occasion; not so much as a vomitory, Dr. Fernel observes, as a sudorific; having this faculty beyond all other emetics, that it corrects the dysentery ferment in proportion as it evacuates it. In the Philosophical Transactions, we have an express discourse on the subject; where it is asserted to be intoluble in all dysenteries and loose stools, how dangerous and inveterate soever; except in splenic and hydropic patients, whose fluxes are indications of approaching death.

Sydenham commends phlebotomy; but Willis says, no evacuation is good, and prescribes not caustic, as spirit of wine a little burnt, &c. Balsamic and styptic medicines are also to be used, according to the diverse causes and symptoms of the disease.

Boric, in a letter to Starboline, affirms there is no better medication in dysentery than rose-water wherein gold has been extinguished.

Doleus relates, that he cured above a hundred persons with oil of sweet almonds, mixed with orange-juice. In this disorder, some, after bleeding and vomiting, give their patients small doses of calomel once a day, till their breath begins to be tainted, the purging being moderated by opiates, glutinous food, drink, and astringent glysters, which is the more necessary, as the guts in this case are easily irritated. Medic. Ed. Edinb. abridg. vol. i. p. 72.

The vitrum antimoniaceum has been found a most efficacious remedy in this distemper. See VITRUM Antimoniacum ceratum.

Repeated doses of ipecacuanha, and of rhubarb with calomel, with opiates in the evening, have also been found successful. Medic. Ed. Edinb. abridg. vol. i. p. 65. where it is observed, that astringent medicines, without gentle revulsions and evacuations, generally retard the cure. For Dr. Fothergill's Observations on the Cure of Fluxes, by small Doses of Ipecacuanha, see Lond. Med. Obs. vol. vi. p. 186.

Ipecacuanha, and the simarouba, have often had great effects in this distemper. See Juslieu in Mem. Acad. Scienc. ann. 1719. This gentleman says, that the simarouba may be compared to, and substituted for the muer of the ancients, which is by some supposed to have been a species in this distemper. See SIMAROUBA.

DYSESTHESIA, from *δυσ*, difficult, and *αἴσθησις*, sensation, in Medicine, is used for a difficulty of, or fault in sensation.

DYSEPULOTICA, from *δυσ*, evil, and *εἰς*, cicatrix, of *εἶδος*, found, in Medicine, great ulcers beyond cure. See ULCER.

DYSOREXIA, from *δυσ*, and *οἶστος*, appetite, in Medicine, a want of appetite, proceeding from an ill disposition, or diminished action of the stomach. See APPETITE.

DYSPEPSIS, from *δυσ*, and *πεψις*, digest, to consume, in Medicine, a difficulty or weakness of Digestion.

The dyspepsis may arise from the too great weakness of the ferment of the stomach, or its being too sparing in quantity; from a relaxation of the fibres of the stomach; the want of a proper heat in the stomach, &c. Bitters and balsamifera are its proper remedy.

DYSPHONIA, from *δυσ*, and *φωνή*, voice, in Medicine, a difficulty of speech from an ill disposition of the organs.

DYSPNOEA, from *δυσ*, and *πνέω*, I breathe, in Medicine, a difficulty of breathing.

D Y S

The *dyspnoea* admits of three degrees: a short breath, an asthma, and an orthopnoea. The short breath is the first and lightest degree. The asthma is more violent, and is accompanied with a wheezing.

The orthopnoea is the highest of all; the patient affected therewith not being able to lie down, but obliged to keep erect, without which he could not respire.

The most usual causes of *dyspnoea* are phlegm lodged in the bronchia, or the too strong constriction of the bronchia themselves, which prevents the easy ingress of the air into the lungs. See *ASTHMA* and *ORTHOPNOEA*.

DYSTHANATOS, from *θω* and *θανω*, *dying*, a word used by the ancient writers, sometimes to signify any disease which occasions a painful and slow death, and sometimes for the person dying in such a lingering manner.

DYSURIA, *Δυσουρία*, from *δύς* and *ουρά*, *to make urine*, in *Medicine*, a difficulty of making urine, accompanied with pain, and a sense of heat.

D Y T

It is also called *ardor urinae*, because the urine seems to burn the urethra as it issues forth.

The *dysuria* differs chiefly from the strangury in this, that in the strangury the urine only oozes out, as it were drop by drop, whereas in the *dysuria*, when it is made, it streams out without any interruption, and frequently in the proper quantity; thus it also differs from the *ischuria*, which is a total suppression of urine.

The ordinary causes of the *dysuria* are, the acrimony, or sharpness of the urine, and the exoriation or exulceration of the neck of the bladder, or of the urinary passage.

The usual remedies in this case are cooling laxatives and mucilaginous medicines, as gum arabic, dissolved in barley-water; decoctions of marshmallow-root, with or without nitre; camphor, and small doses of laudanum. See *ISCHURIA* and *STRANGURY*.

DYTISCUS, in *Zoology*. See *WATER-BEETLE*.

E.

E, The fifth letter of the alphabet, and the second vowel.

E is a letter that admits of some variety in the pronunciation, in most languages; whence grammarians usually distinguish several *E's*, or kinds of *E*. In English, *E* has two sounds; long, as *scène*, and short, as *min*. *E* final has the peculiar quality of lengthening the preceding vowel, as *cân, câne*; yet there are some instances in which it has not this effect; as *pâte*, &c. It serves also to modify the foregoing consonants; as *fine*, &c. It is also founded at the end of proper names; as *Prinsipe*, and in monosyllables that have no other vowel, as *the*; but in every other case it is mute. It was formerly used much more generally at the end of words than at present, and had probably a soft sound like the French *E* feminine; and afterwards was made vocal or silent in poetry, as the verse required, till at last it became universally silent. Camden calls it the silent *E*. Johnson.

The Greeks have their short and long *E*, viz. *e* and *ē*, *epilon* and *eta*. The Greek *e*, or *H*, *eta*, or *ira*, was no original letter; but was added to the alphabet in after times. Of this we have proofs still extant in the ancient monuments; particularly, the *Farnese columns*, brought to Rome from the *Via Appia*, where the *epilon*, *E*, is used in lieu of the *H*: e. gr. *DEMETPOΣ KOPEE*, for *DEMETPOΣ KOPIH*. This letter is said to have been added by Simonides.

The pronunciation of the *e* seems to have been varied; it having been sometimes the same with the Latin *E*, sometimes with *I*. Terentianus assures us of the former; and the Greeks themselves for many ages have only used the latter.

The Latins have an open *E*, called *casilar*; such was the second *E*, in the word *hera*, *mitra*; and another closer, as that in the adverb *hera*, *spidera*. This latter *E* they frequently used promiscuously with *I*. Thus for *hera*, they wrote *heri*; and, in divers places, we meet with *sile*, *quis*, &c. for *sili*, *quis*, &c.

The Roman *E* was likewise sometimes written, by corruption, *ε*; for which reason, F. Hærlouin takes that medal of Gallienus, *GALLIENS AUGUSTVS*, not to be any satirical medal, as others have imagined; nor to be a dative feminine, but a vocative masculine, *Gallienus dæ-gustis*, wrote with the *ε*.

It has been much disputed how the Latins render the *e* in their language. The common opinion is, that they render it by an *E*; as in *Quæstus*, *Beta*, *Maya*, *Oneros*, *Onerosus*, &c. which they rendered *Demetrius*, *Beta*, *Hemera*, *Thelus*, *Thesaurus*, &c. Though there are persons exceedingly well versed in antiquity, who hold that they pronounced it like an *i*. Lud. de Dieu, one of the most learned grammarians of his age, observes as much in his animadversions on Genesis vi. 24. Adding, that it is for this reason, that the Hebrews, e. gr. the paraphrast Jonathan, express it by a *Heth*; *מֵטָר*, *metar*. J. Rod. Wetstein proves the same in his learned oration on the true pronunciation of the Greek tongue, from an infinity of instances. To this purpose he cites a manuscript Folio of the eighth century, where all the *e's* are expressed by *i's*. In effect, Wetstein shows, not only that the Latins pronounced and wrote it as an *i*, which might happen from its being so easily confounded in writing with an *i*, but also that they rendered it by an *ε*, and *ε*; that it was often used

* For *E* and *E*; and that in the time of Plato this letter had a kind of intermediate sound between the *e* and *i*. See that author, and Vossius de Idol. lib. ii. cap. 16.

The French have, at least, six kinds of *E*; the first pronounced like *e*; as in *imperier*, *orient*, &c. The second, a final mute, in the last syllable of diverse words not pro-

nounced at all; as in *lower*, *dance*, &c. The third, an imperfect mute, pronounced much like the diphthong *ey*, &c. as in *je*, *de*, *te*. The fourth, *e* *ferme*, or *e* *major*, marked at the ends of words with an accent, *e*. The fifth, is *e* *ouvert*, or *long e*, having the same sound with *ai*; as in *maître*, *sister*, &c. In the middle of words it is sometimes marked with a circumflex, and in the end, with an accent, *e*. The sixth, is an intermediate *e*, between the *ouvert* and *ferme*, as in *colaret*, *littere*, &c. Some add a seventh kind of *e*, not reducible to any of the former, as that in *grammarian*, *histrion*, &c. And others admit of only three kinds, viz. the mute, open, and shut; but they make variations therein, which amount to the same thing.

As to the figure of the letter *E*, we borrow it from the Latins, who had it from the Greeks, and they from the Phœnicians, by Cadmus, who first brought it thence. Now the Phœnicians had the same characters with the Hebrews. Accordingly, the form of the ancient Hebrew *He* was the same with that of our *E*, as may be seen in the Hebrew medals, and the Jesuit Souci's Dissertation thereon, p. 143. All the difference between them consists in this, that the Hebrews, reading from right to left, turn their letters that way; whereas the moderns, reading from left to right, write their letters accordingly.

The little *e* was formed of the great one, by writing it tall, and making the cross strokes at top and bottom without taking pen off paper, and then adding the stroke in the middle.

E, on the keys of an organ, or harpsichord, denotes the tones, *E*, *mi*, *la*.

On the compass, in sea-charts, &c. it marks the east point, or wind. *E* east; *E. S. E.* east-south-east; *N. E.* north-east, &c.

In the calendar, *E* makes the fifth of the Dominical letters.

Among authors, *e* *gr*, stands for *exempli gratia*, for instance. In several dictionaries we find it noted, that the letter *E* among the ancients, was a numeral letter, signifying 250, according to the verse,

E quæque ducentis & quinquaginta tenet.

But it has already been observed, that this use of numeral letters was unknown among the earliest people. Isidore Hispalensis, an author of the seventh century, says as much in express terms, in the first book of his *Origines*, cap. 3. In effect it was first introduced in the times of barbarism and ignorance.

EADISIL. See **EDITHA**.

EAGER/Tame. See **WING**.

EAGLE, *Aquila*, *Aeror*, in *Ornithology*, the largest, strongest, and swiftest, of all the birds that live by prey.

In the Linnæan system it is a species of the **FALCON**. See **Tal. of Birds**, N° 1.

It has a long beak, hooked almost from the root; yellow legs, which are feathered to the toes; and the toes are covered with large scales, thick, crooked talons, and a short tail, of a deep brown, with waves of ash-colour, and usually white at the roots of the feathers. Its plumage is chestnut-coloured, brown, rusty, and white. Its beak black at the tip, and in the middle blue, though in some yellow. The *scutellus* is distinguished from the hawk by his legs; and from the vulture, by the crookedness of his beak.

This is the golden eagle of some authors, the *falco chryseus* of Linnæus, and the *regal eagle* of others.

Its cry, or note, is usually on the highest rocks, sometimes on the tops of old trees. It feeds its young all such time as they are able to fly, and then drives them out of the nest.

Its food is birds, hares, lambs, kids, and fawns; nay, Sir Robert Sibbald affirms us, children too, when it can catch them; of which he gives an instance in the Orcales Islands. Prod. Nat. Hist. Scot. lib. iii. p. 2. and 14.

Ray mentions an eagle's nest found near the river Derwent, in 1668. It consisted of large strong sticks, one end whereof was laid on the crag of a rock, and the other on two beech trees; it was two yards square; in it was found one eagle, with the carcass of a lamb, one hare, and three greyhounds. Synopf. Methpd. Av. p. 6.

The eagle frequently watches the fishing hawk, and as soon as it perceives it to have struck a fish, takes wing, and pursues the bird till it lets fall its prey, and often catches it before it reaches the earth or water. Phil. Transl. N^o 201.

Eagles are remarkable for their longevity, and for their faculty of sustaining a long abstinence from food. Keyser relates, that an eagle died at Vienna after a confinement of a hundred and four years, which justifies the allusion of the Psalmist. Psalm cii. 5.

Its sight is quick, strong, and piercing, to a proverb. Job xxxix. 29. The reason why the eagle, the fibres of whose optic nerves are not stronger than those of other animals, is able to face the sun, and endure its brightest rays, the Jesuit Angelus, in his Optics, assures us, is, that it has two sets of eye lids, the one thick and close, and the other thinner and finer, which last it draws over the eye, when it looks at any luminous body, and thus breaks the force of its rays.

The falcons have trained up eagles to the game; but they only succeed in mountainous countries. On plains they cannot keep any time on the wing; and when they stoop, or light, are weak, so that the fakes beats them.

Aristotle, and Pliny, reckon up six kinds of eagles, to which they give names corresponding to the difference of their plumage: as the eagle-regal, called by Aristotle *gryphos*, and *gryphus*, from the roddy, golden colour of its feathers, which are likewise spotted as it were with stars. The black-eagle, *melanotos*, the smallest and most vigorous of all. The white-headed eagle, or *pygargus*. The middle-sized eagle, with a large tail, living in mountains, *merops*. The fire-eagle, *haliaetus*. And the barred-eagle, a kind of *gryphus*.

EAGLE, *black*, a species called also *agilis valeria* by some authors. It is a small eagle, with the bigness of a crow. Its jaws and eye-brows are destitute of feathers, and look reddish; its head, neck, and breast, are black, and in the middle of its back it has a large triangular spot, of a pale brownish red, with something of white-necks intermixed. Its rump is a reddish brown, and its wings variegated with black, white, and grey. Its beak is not large, black at the end; the skin, covering the nostrils, red; and the iris of his eyes hazel-coloured. His legs are feathered a little below the knee, and below that are red; and the claws very sharp. Willughby's Ornithology, p. 30.

EAGLE, *crested*, in Ornithology, a name under which Nicomachus has described an American species of bird, of the eagle kind, called by the Indians *yanabith*. It is, by much, the largest of all the eagles, yet it is easily tamed, and fitted for the diversions of hawking. This is placed by Mr. Ray among the birds, the descriptions of which he is very suspicious of. Ray's Ornithol. p. 299.

EAGLE, *sea*, in Ornithology, a name used by some authors for the *HALIAETUS*, or alpey.

EAGLE, *sea*, in Ichthyology, the name of a species of cartilaginous fish, of the *palmaria marina* kind. It is generally found small, but sometimes grows to a very large size. Its head is large for a fish of this genus, and somewhat resembles a toad's in shape; its eyes are large and prominent; its mouth is placed in the under part of the head, and is large, and furnished with strong teeth. Its fins are broad and thin, and represent the expanded wings of an eagle, whence it had its name. See *Tab. of Fishes*, p. 25.

EAGLE, *common*, in Zoology, *Falco sabus* of Linnæus, is a species common in the northern parts of Europe and America. This is called, in Scotland the *black-eagle*. From the dark colour of the plumage. It is about the same size with the golden eagle; the bill is of a blackish horn colour, the cere yellow, and the whole body is of a deep brown, slightly tinged with rust colour; but its distinguishing characteristic is a band of white on the upper part of the tail. The legs are feathered to the feet, the toes are yellow, and the claws black. The white tailed eagle of Canada is a variety of this, differing only in some white spots on the breast. See *FIGURE*.

EAGLE, in Heraldry, the king of royalty, as being, according to Philostratus, the king of birds; and for that reason dedicated, by the ancients, to Jupiter.

This eagle is the arms of the emperor, the king of Poland,

&c. It is accounted one of the most noble bearings in heraldry, and, according to the learned in that art, ought never to be given, but in consideration of singular bravery, generosity, &c. On which occasions either a whole eagle, or an eagle's *naissant*, or only the head, or other parts, agreeable to the exploit, may be granted.

The eagle is sometimes represented with one head, and sometimes with two, though never more than one body, two legs, and two wings opened, or stretched out, in which posture it is said to be spread or displayed: such is that of the empire, which is blazoned a spread eagle, *folded, disarmed, langued, beaked and membered, gules*.

The reason why eagles are generally given in heraldry displayed, is partly, because in that posture they fill up the circutcheon better, and partly because it is imagined a posture natural to the eagle, when it plumes its feathers, or faces the sun. However, there are eagles borne in other postures; and some monstrous ones, with human or wolves heads, &c. The late authors only say displayed to express the two heads; and say an eagle, without any addition, when it has but one. The kingdom of Poland bears *gules, an eagle argent, crowned and membered, or*.

The eagle has been borne, by way of ensign, or standard, by several nations. The first who seem to have assumed the eagle were the Persians, according to the testimony of Xenophon. Afterwards it was taken by the Romans; who, after a great variety of standards, at length fixed on the eagle, in the second year of the consulate of C. Marius: till that time they used indifferently wolves, leopards, and eagles, according to the humour of the commander.

Several among the learned maintain, that the Romans borrowed this custom from Jupiter, who had appropriated the eagle as his own badge, in commemoration of its supplying him with nectar, while he lay concealed in Crete, for fear of being devoured by his father Saturn. Others hold that they borrowed it from the Tuscans, and others from the Epirotes.

The Roman eagle, it must be observed, were not painted on a cloth, or flag; but were figures in relief, of silver or gold, borne on the tops of pikes; the wings being displayed, and frequently a thunderbolt in their talons. Under the eagle, on the pike, were piled bucklers, and sometimes crowns. Thus much we learn from the medals. See Felchius in his *Disert. de Insignibus*. And Lipsius, *De Militia Romana*, lib. iv. dial. 5.

Constantine is said to have first introduced the eagle with two heads, to intimate, that though the empire seemed divided, it was yet only one body. Others say, that it was Charlemagne, who returning the eagle, as the Roman ensign, added to it a second head; but that opinion is destroyed by an eagle with two heads, noted by Lipsius, on the Antonine column; as also by the eagle only having one head on the seal of the golden bull, of the emperor Charles IV. The conjecture, therefore, of F. Menestrier appears more probable, who maintains, that as the emperors of the East, when there were two on the throne at the same time, struck their coins with the impression of a cross, with a double traverse, which each of them held in one hand, as being the symbol of the Christians; the like they did with the eagle in their emblems; and instead of doubling their eagle, they joined them together, and represented them with two heads. In which they were followed by the emperors of the West.

F. Papebroche wishes, that this conjecture of Menestrier were confirmed by ancient coins; without which, he rather inclines to think the use of the eagle with two heads to be merely arbitrary; though he grants it probable, that it was first introduced on occasion of two emperors in the same throne.

The eagle on medals, according to M. Spanheim, is a symbol of divinity, and providence; and, according to all other antiquaries, of empire. The princes on whose medals it is most usually found, are the Ptolemies and the Seleucides of Syria. An eagle with the word *INTEGRITAS*, expresses the apothecosis of an emperor.

EAGLES, a name found very frequently in the ancient histories of Ireland, and used to express a sort of base money that was current in that kingdom in the first years of the reign of Edward the First, that is, about the year 1172. There were, besides the eagle, lions, roses, and many other coins of the same sort, named according to the figures they were impressed with. Simon's Hist. Coins.

The current coin of the kingdom was at that time a composition of copper and silver, in a determined proportion, but these were so much worse than the standard proportion of that time, that they were not intrinsically worth quite half for much as the others. They were imported out of France, and other foreign countries. When this prince

prince had been a few years established on the throne, he set up mints in Ireland for the coining of sufficient quantities of good money, and then decided the use of these eagles, and other the like kinds of base coins, and made it death, with confiscation of effects, to import any more of them into the kingdom.

EAGLE, *Aquila*, in *Astronomy*, is a constellation of the northern hemisphere, having its right wing contiguous to the equinoctial.

For the stars in this constellation, their number, longitude, latitude, &c. See *AQUILA*.

There are also three several stars, particularly denominated among the Arab astronomers, *Nasr*, i. e. eagle. The first, *Nasr Sebail*, the *Eagle of Canopus*, called also *Sitarab Yemen*, the star of Arabia Felix, over which it is supposed to preside; the second, *Nasr Alhaur*, the *Eying Eagle*; and the third, *Nasr Almoat*, the *Resting Eagle*.

EAGLE, *White*, is a Polish order of knighthood, instituted in 1325, by Uladislav V. on marrying his son Calimire with a daughter of the great-duk of Lithuania.

The cavaliers of this order were distinguished by a gold chain, which they wore on the stomach, whereon hung a silver eagle crowned.

EAGLE, *Black*, was a like order, instituted in 1701, by the elector of Brandenburg, on his being crowned king of Prussia.

The knights of this order wear an orange-coloured ribbon, to which is suspended a black eagle.

EAGLE, in *Architecture*, is a figure of that bird anciently used as an attribute, or cognizance of Jupiter, in the capitals and friezes of the columns of temples consecrated to that god.

EAGLE-flower. See *BALSAMINE*.

EAGLE-stone, in *Natural History*, a stone, by the Greeks, called *astres*, and by the Italians, *pietra d'aquila*, as being supposed to be sometimes found in the eagle's nest. It is of famous traditionary virtue, either for forwarding, or preventing, the delivery of women in labour, according as it is applied above, or below, the womb.

Mathiolus tells us, that birds of prey could never hatch their young without it, and that they go in search for it as far as the East Indies. Jausch has an express Latin treatise on the subject. See *ASTITES*.

EAGLET, or **EAGLON**, a diminutive of eagle, properly signifying a young eagle.

The eagle is said to prove his eaglets in the brightness of the sun; and if they shut their eye-lids, he discloses them. In *Heraldry*, when there are several eagles on the same escutcheon, they are called *eaglets*.

EALDERMAN, or **EALDORMAN**, among the Saxons, was of like import with *earl* amongst the Danes. Camden's Britan. p. 107.

The word was also used for an elder, senator, or statesman. Hence, at this day, we call those *aldermen*, who are associates to the chief officer in the common-council of a city or corporate town.

EAR, *Auris*, the organ of hearing; or that part whereby animals receive the impression of sounds.

The ear is generally divided into *internal* and *external*. The *external*, or *outer ear*, in most animals, consists of two principal parts, viz. that which appears prominent from the head, called the *auricles*; and an inner part, which enters the skull by a narrow passage, called the *meatus auditorius*; and leads to the *auris* or ear, properly so called.

The *auricles*, or outer part of the *external ear*, is semicircular, and contains divers sinuities. Its upper part, which is the broadest, is called *pinna*, and sometimes *ala*; and the lower, which is narrower, softer, and pendant, the *lobes*, or *flaps*, being that to which ladies hang their ear-rings, &c. The outer area, or extent of the *auricles*, is called the *helix*; and the inner, oblong prominence, surrounded by it, the *antihelix*; the little protuberance of the side next the face, is called the *tragus*, or *tricus*; and the ridge just above, and opposite to it, the *antitragus*; and the cavity, leading to the beginning of the *meatus*, the *concha*. See each part described under its proper article.

The *auricle* stands out from the head, and is furrowed with divers winding canals, which receive and collect the wandering circumambient impressions, and undulations of sound, and modify and forward them to the inner ear. It is formed of a thin cartilage, covered with a skin. It has two muscles, which in men are very small, whence some anatomists deny there are any at all, though others increase their number to three, one at the bottom, and two retransversary, and others to four. But in brutes, which move and prick the *ears*, as horses, asses, &c. they are very large and considerable. Those who have lost their *auricles*, M. Dionis observes, have but a confused way of hearing; and are obliged either to form a

cavity round the ear with their hands, or to make use of a horn, applying the end of it to the *meatus auditorius*.

The inner part of the *external ear* is possessed by the *meatus auditorius*, or auditory passage, which commences from the bottom of the concha, called the *os tympani*, and is continued in a winding direction, turning sometimes this way, and sometimes that, to the *membrana tympani*. The *meatus* is dug out of the *os temporis*, and lined with a skin, or membrane, which is furnished with divers little glands, that secrete a thick, yellow, glutinous humour, called *cerumen*, or ear-wax, serving to defend the ear from the ingress of vermin, and other extraneous bodies, and cellular membrane. This *meatus* is all the *external ear*, in diverse animals, as reptiles, birds, moles, divers fishes, &c. The farther end thereof is closed by a thin, dry, round, transparent membrane, called the *membrana tympani*, and improperly *tympanum*, or drum, which separates the *external ear* from the *internal*. The arteries of the *external ear* come anteriorly from the *arteria temporalis*, and posteriorly from the *occipitalis*, which is a branch of the *external carotid*. The veins are rami of the *jugularis externa*.

Behind the *membrana tympani*, is a cavity called, by different authors, the *tympanum*, *caulus tympani*, *caula interna*, and *meatus auditorius internus*. In this cavity are five considerable parts; viz. four little bones, two apertures, called *foramina*, or *fenestrae*; as many muscles, or passages; four muscles, and a branch of a nerve.

The first of the bones, or ossicles, is the *malleus*, *mallet*, or hammer; the second, is called the *incus*, or anvil; the third, the *stapes*, or stirrup; and the fourth, the *orbicularis*. These bones are nearly of the same bigness at the birth of the child, as when arrived at maturity, so that all that age does is to harden them.

To give motion to these bones, is the office of the four muscles of this cavity; three of them belonging to the *malleus*; viz. the *externus*, *obliquus*, and *internus*; and the fourth to the *stapes*, called the *musculus stapedia*.

The two meatuses are situated at the sides of the cavity; the one opening into the palate, called *aquaductus*, or Eustachian tube; the other, shorter and bigger, opening into the sinus, in the mammillary process.

The two apertures, or *fenestrae*, of the tympanum, are in the surface of the *os petrosum*, which is opposite to the membrane of the tympanum. The first, called *fenestra ovalis*, because of its figure, is situate a little higher than the other, and receives the basis of the *stapes*. The other is called *retunda*, notwithstanding its figure is oval, like the former, and is closed by a thin, dry, transparent membrane, resembling that of the tympanum.

The last thing considered in the cavity of the tympanum is a fine chord, which runs over the inner surface of the membrane, called *chorda tympani*. Anatomists have long disputed, whether it was an artery, a vein, or nerve; or the tendon of one of the muscles of the malleus; but it is now discovered to be a branch of the fifth pair of nerves, which meets the *petrus dura* of the auditory nerve.

The two *fenestrae* above mentioned open into a cavity dug out of the *os petrosum*, called the *labyrinth*, as being perplexed with divers windings and meanders: in this cavity is supposed to be contained the *innate air*. It is divided into three parts, which are lined by a fine periotum, in which, and also through the whole extent of the periotum of the inner ear, may be discovered a great number of blood-vessels; the first is called the *vestibule*, because it leads into the other two; in it are observed nine apertures, or foramina. The second, placed on one side of the vestibulum, towards the back of the head, comprehends three round canals, disposed in a semicircular form, and thence called *canaluli semicirculares*. The third is the *cochlea*, which consists of two parts, viz. a spiral semi-oval canal; and a lamina, formed into a spiral flight. The canal makes two turns and an half round a newel, or axis, still growing less as it ascends; the spiral lamina divides this cavity into two, being fastened by its base to this newel; and, by its other extremity, to the surface of the canal opposite to the newel, by means of a very fine membrane. The cavity of the cochlea, thus divided, forms, as it were, two winding stair-cases, both formed on the same newel, one over the other, but without any communication between them. In the aqueduct is the auditory nerve; which consists of two branches, or parts; the one soft, called *portio mollis*, and the other harder, *portio dura*; the soft part is spent on the organ of hearing, being divided into five branches, which form a delicate web, that lines the vestibulum, cochlea, &c. The hard part passing through the whole bony duct called *aqueductus Philippi*, out of the cranium, is distributed among the parts of the *external ear*, &c. The other vessels of the internal ear are arteries and veins from the carotids and jugulars. Particular descriptions of each

each part of the ear, see under *FENESTRA*, *FORAMEN*, *MALLEUS*, *STAPES*, *ORBITALARE*, *LABYRINTH*, *VESTIBULE*, *COCHLEA*, *AUDITORY NERVE*, &c. The immediate organ of hearing has been generally supposed to be the membrane of the tympanum; but later anatomists shew this to be a mistake, from divers instances, wherein that membrane has been absolutely destroyed, and broken, without the least diminution of the sense of hearing.

The parts that bid the fairest for this prerogative, are those which compose the labyrinth; viz. the cochlea, lamina spiralis, vestibule, and semicircular canals; the portio mollis of the auditory nerve, ramified and distributed through these parts, receives the impressions of sound, and propagates them to the brain.

The compilers of the Royal Society of Physicians at Paris, appointed to examine the work of M. Geoffroy, entitled *Differtations sur l'Organe de l'Oue de l'Homme, des Bestes, des Poissons*, published in 1778, infer, from the facts and observations which he has recited, that the impression made on the branch or part of the auditory nerve, called the *portio mollis*, is sufficient to produce the perception or sensation of sound; that the semicircular canals render this perception more lively and intense; and that the cochlea adds little to the intensity of the impression, but the small bones, or ossicles, considerably; and that the human species, quadrupeds, and cetaceous fishes, form the first class of animals, whose organ of hearing is the most subtle, and of the most perfect construction; that birds are to be placed in the second; reptiles, who have the external marks of a tympanum, in the third; cartilaginous fishes in the fourth; spinous or prickly fishes in the fifth; fishes of the eel-kind, which seem to have only two semicircular canals completely formed, in the sixth; and serpents, who appear to have no semicircular canals, in the seventh.

Behind, and under the external ear, are a number of large glands, called *parotides*, wherein is separated a great deal of saliva; which is conveyed, by the excretory ducts, into the mouth.

Diseases incident to the ear, and adjacent parts, are noise, *OTALGIA*, *DEAFNESS*, &c.

EARS, wounds of the. Wounds of the external ear are easily united by sticking-plasters, unless the cartilage is entirely divided, and then it will require the help of the needle, and the application of vulnerary balsams, with the proper compresses and bandages. When the ear is wounded in the neighbourhood of the meatus auditorius, great care must be taken to prevent the discharge of blood and matter into that passage, which would do great mischief to the tympanum; but this may be done only by filling the internal ear with lint or cotton. Heister's Surgery, p. 8.

M. Le Cat, in his Treatise of the Organ of Sound, has new figures of several parts of the ear. Med. Ess. Edinb. ubi. tom. II. p. 481.

We have also some treatises on the ear by Dr. Calkbourn, containing very minute descriptions of the parts. Ibid.

EARS, running of the, in infants. See *INFANT*.

The comparative anatomy of the ear furnishes abundant instances of the Creator's wisdom. In birds, the outer ear is of a form proper for flight; not protuberant, as that would obstruct their progress, but close and covered. In quadrupeds, its form is agreeable to the posture and motion of the body, but admirably varied, according to their various occasions: in some, as the hare, it is large, open, and erect; by which means that timorous, defenceless creature, is warned of the least approach of danger: in others, it is covered, to keep out noxious bodies. In the subterraneous quadrupeds, who are forced to mine and dig for their food and habitation, as a protuberant ear would obstruct them, and be liable to injuries, their ears are very short, and are lodged deep, and backwards in the head.

Thus moles have no auricle at all, but only a round hole, between the neck and shoulder. Some authors observe, that this meatus, or passage, is closed with a little skin, which opens and shuts like an eyelid. The sea-calf, and the several species of lizards and serpents, are likewise without any external ear. And the tortoise, camelion, and generality of fishes, have the passage of the ear quite stopped, or covered over. And there is a sort of whale, which has the aperture of the ear under the shoulder.

Among all the varieties in the structure of this organ, none, as Dr. Greve observes, are more remarkable than those in the passage into the os perrotum; for in an owl, which perches on a tree, or beam, and hearkens after the prey beneath her, it is produced farther out above, than below, for the better reception of the least sound: in a fox, which scouts underneath the prey at root, it is, for the same reason, produced farther out below: in a pole-cat, which hearkens straight forwards, it is produced behind, for the taking of a forward sound; where-

as in a hare, which is very quick of hearing, and thinks of nothing but being pursued, it is supplied with a bony tube, directed backwards, so as to receive the smallest and most distant sound that comes behind her.

Schellhammer denies the existence of the innate air, so much talked of, in the labyrinth; and with good reason, as there is a passage out of the labyrinth into the throat, through which the innate air must escape. This is past doubt; since, by stopping the breath, and straining, we can force the external air into the ear, and even hear it rushing in. When the passage is any way stopped, as by a cold, &c. the hearing thereby becomes dull and obtuse; and when, by strong swallowing, or other motion of the throat, the passage is opened, we perceive it by a sudden crack, and immediately hear very clearly; the load of excrement air being then discharged from the innate ear.

Several naturalists and physicians have held, that cutting off the ear rendered persons barren, and unprolific; and this idle notion was what first occasioned the legislators to order the ears of thieves, &c. to be cut off, lest they should produce their like.

The ear has its beauties, which a good painter ought by no means to disregard; where it is well formed, it would be an injury to the head to be hidden. Suetonius insists particularly on the beauties of Augustus's ears; and Elian, describing the beauties of Aliphan, observes she had short ears.

Martial also ranks large ears among the number of deformities. Felibien.

Among the Athenians, it was a mark of nobility to have the ears bored, or perforated. And among the Hebrews and Romans, this was a mark of servitude.

Lots of one ear is a punishment enacted by 5 and 6 Ed. VI. cap. 4. for fighting in a church-yard; and by 2 & 3 Ed. VI. cap. 15. for combinations to raise the price of provisions, labour, &c. if it be the third offence, beside pillory, and perpetual infamy, or a fine of 40*l*.

By a statute of Henry VIII. maliciously cutting off the ear of a person is made a treason, for which treble damages shall be recovered; and the offender is to pay a fine of ten pounds to the king. 37 Hen. VIII. cap. 6. § 4. In the Index to the Statutes at Large, it is said, that this offence may be punished as felony, by 22 & 23 Car. II. cap. 1. § 7, commonly called Coventry's act; but ear is not mentioned in that statute.

EAR, tingling of the. See *TINNITUS*.

EAR, in Music, denotes a kind of internal sense, whereby we judge of musical sounds and harmony; they who possess this sense are said to have a good ear. And the like distinction we should probably acknowledge in other affairs, had we got distinct names to denote those powers of perception by.

Thus, a greater capacity of perceiving the beauties of painting, architecture, &c. is called a *fine taste*. See *TASTE*.

EAR-ACH. See *OTALGIA*.

EAR of fishes. All the cetaceous fishes have external meatus auditorii, or passages for hearing; but other fish have nothing of these external appearances, and seem neither to be intended by nature to make any sounds, or to hear any. Though sound being a tremulation in the air, it may be felt by them as motion, though not distinguished as sound. It may easily be proved, that they do not hear our voices in speaking, by walking near the side of a pond or river well stored with fish about the edges; if the body and its shadow be kept out of their sight, they will never start at the voice.

Yet how far fishes are deaf and dumb, seems a question not yet perfectly decided. See *FISH*.

EAR, in Gardening, a name given to the feminal leaves of plants, or those two green and succulent leaves which first appear from the seed, and are very different, in all respects, from those which follow. Thus in the melon plants, the two first leaves are called ears; and the leaves, with their stalks, which shoot out afterwards, are called knots, and denominated the first, second, and third knot, according to their place, and time of growing. The cutting off every third knot in this plant, is the great means of procuring the finest and largest fruit. Phil. Trans. N^o 45.

EAR, in Botany, is also applied to a long cluster of flowers, or seeds, produced by certain plants; and usually called, by botanists, *spica*. The flowers and seeds of wheat, rye, barley, &c. grow in ears. The same holds of the flowers of lavender, &c.

We try, the stem of the ear, i. e. its tube, or straw: the knot of the ear, the lobes, or cells, wherein the grains are enclosed; the beard of the ear, &c. great numbers of ears of wheat have been known to arise from the same root.

EAR, TWEED. See *AURICULA TWEED*.

EAR-picks, are instruments of ivory, silver, and other me-

tal, somewhat in form of a probe, for cleaning the ear. The Chinese are particularly fond of entertaining themselves with picking and tickling their ears; this they do either for themselves, or interchangeably for one another, and have a great number of instruments of peculiar shapes and fracture, invented for this purpose. But Sir Hans Sloane very judiciously observes, that the use of them seems very prejudicial; for that, among many people in England who had applied to him on account of deafness, the far greater part were thrown into their complaints, by too often picking their ears, and thereby bringing humours, or ulcerous dispositions, on them. Phil. Trans. N° 246. p. 406.

EAR-RING. See PENDANT.

EAR-WORM. See CERVIUM.

EAR-WORM. *Forficula*, in *Zoolia*, the name of a genus of insects, of the order of *coleoptera*, the tail of which forms a kind of forceps, capable of pinching; the exterior wings are very short, but dimidiated; and the antennae are setaceous. It has six feet; its body is about the thickness of a small worm, and very smooth.

It is a very troublefome creature, frequently introducing itself into the ear, and causing a great deal of pain by its biting; it likewise burrows in other parts of the body, which it bites in the same manner.

They are likewise very pernicious in gardens, especially where carnations are preferred. In order to prevent the mischief attending them, it is usual to erect stands, supporting basins of water, or to hang the hollow claws of crabs or lobsters on sticks in different parts of the garden, in which they lodge.

The dried powder of ear-worms is esteemed good for deafness; and the oil prepared from them, in convulsions and spasms. Vide Lemery, Dict. des Drog. in voc. *Forficula*.

EAR-WIG. See *POICILICA Marina*.

EAR-SHELL. *Auric Marina*, in Natural History, the name of a genus of shell-fish, the characters of which are these: it consists only of one shell, or valve, and is of a flattened shape, its concave measure resembling that of the human ear, and has an extremely wide mouth, or aperture, at its base, the widest of that of all shells, except only the patella or limpet, which is all mouth below. See *Tab. of Shells*, N° 3.

In the Linnæan distribution this is a species of the *MA-LIOID*.

Aldrovand and Rondeletius have given this genus the name of *patella fœrea*, the wild limpet; but in this they have been followed by no author, as it confounds the *auric marina* and *patella*, which are two absolutely distinct genera. These authors have also ranked both this and the limpet among the bivalve shells, but nothing can be more absurd than this.

This genus of shells sometimes yields small pearls, the rudiments of which are very frequently seen in those shells which have not perfect ones, and the whole inside of the shell is of the colour of the flesh mother of pearl. This also appears on the outside, when the rough coat is so far eaten away by acids, as to leave this pearly surface bare; in this case it makes a very elegant appearance, being of the splendour of the most perfect mother of pearl both within and without, and it is frequently preserved in cabinets in this state.

The inside and outside of this shell are both rigid with very high ribs, which run from one side to the other; and there is in all these shells a row of holes near one edge, of which six are usually open, and there are beyond these the marks of three or four others, which do not go through the shell. These are formed in the growth of the fish, which, as it enlarges, enlarges also the shell; and when a new rim is formed, in which there is an open hole, one of the hinder ones is always closed up by the growth of flesh thence matter over it. Aldrovand. de Aquat. Rondelet. de Aquat.

There is one very singular species of *auric marina*, which differs from all the others in its length; it is large, and brought from the East Indies, but is not found in the European seas. The general species of *auric marina* are four: those with six holes; those with seven, and which are more pearly than the rest; those of an oblong form; and those which have no mark of aperture at all. Hist. Nat. Ecclaire. part ii. p. 243, 244.

EAR OF CORN. In Rome. See *Tab. of Fossils*, Class 6.

EARLINE COATS. from *ear*, spring, among the ancient Greeks, a habit worn in the spring, which was made of wool, and dyed green. The custom of wearing green vestments in this season, has not been unknown in modern times.

Dempster says, it was customary, in his time, for the king, and nobility of England, to go a-hunting in the spring, dressed in green, that they might be of a similar colour with the season.

EARING. in a ship, that part of the belt-rope, which, at the four corners of the sail is left open, in the shape of

a ring. The two uppermost parts are put over the ends of the yard-arms, and so the sail is made fast to the yard; and into the lowermost *earings* the sheets and tackles are seized, or bent at the clew.

EARING Third. in *Haybandry*. See THIRD.

EARL. an English title of honour, or degree of nobility, next below a marquis, and above a viscount.

Earls were anciently attendants or associates of the king in his councils, and martial expeditions; much as comites, counts, were of the magistrates of Rome, in quality of deputies, to execute their offices for them.

Hence, also, *earls* are called, in Latin, *comites*; in French, *comtes*, counts, &c. The Germans call them *graves*, as landgrave, markgrave, palgrave, &c. The Saxons, *caldermans*; the Danes, *earls*, and the English, *earls*.

Earl was a considerable title among the Saxons; it is observed to be the most ancient of any of the peerages; and that there is no other title of honour in use among the present nobility, which was likewise used among the Saxons, beside it. The original titles of honour among the Saxons, were *eorling*, *calderman*, and *degen*, or *degn*. The first appropriated to those of the royal family; the other two to the rest of the nobility; only the thani were afterwards distinguished into majores and minores. Originally the title *earl* always dyed with the man. William the Conqueror first made it hereditary, giving it in fee to his nobles, and annexing it to fiefs or counties; for the support of the state thereof, he allotted the third penny out of the sheriff's court, issuing out of all places of the fief from which the *earl* took his title. But, of later days, the matter is much altered.

Earls are now created by patent, without any authority over, or particular relation to, their counties; and without any profit arising thence, except some annual stipend out of the exchequer, for honour (sake). The number of *earls* being of late much increased, and no more counties being left for them, several of them have made choice of some eminent part of a county, as Lindsey, Holland, Crayen, &c. Others of some town, as Marlborough, Exeter, Bristol, &c. And others, of some village, or their own seat, park, &c. as Godolphin, Bolton, Dauby, &c.

Some *earls* we have who are not local, i. e. not dignified from any place, but from noble families, viz. *earl Rivers*, and *earl Faulkner*. A third is denominated from his office, viz. the *earl Marshal*.

Earls are created by cincture of sword, mantle, a cap, and a coronet put on his head, and a charter in his hand. Their title is *most potent and noble lord*. Their coronet has the pearls set on points, with leaves between.

Their place is next to a marquis, and before a viscount; and as, in very ancient times, those who were created counts or earls, were of the blood royal; our British monarchs to this day call them in all public writings *earls of the royal blood*, an appellation as ancient as the reign of Henry IV. They also originally did, and still may, use the style of *my*.

EARL-MARSHAL is one of the great officers of the crown; who takes cognizance of all matters relating to honour and arms, determines contracts that respect deeds of arms out of the realm upon land, and matters concerning war within the realm, which cannot be determined by common law, in which he usually proceeds according to the civil law. He had, anciently, several courts under his jurisdiction, as the court of chivalry, now almost forgotten; and the court of honour.

He has also some pre-eminence in the court of marshals, where he may sit in judgment against criminals offending within the verge of the court; whence the chief officer under him is called *deputy-marshal*. Under him is also the heralds office, or college of arms. See COLLEGE and COURT.

The office of *earl-marshal* is hereditary in the family of Howard; and enjoyed by the duke of Norfolk, the principal branch thereof; though now, on account of the religion of the duke of Norfolk, which renders him incapable of administering it in person, it is discharged by deputation; but yet it is to be observed, it is not given out of the name and family of Howard.

EARNEST. *Arrha*, money advanced to complete or assure a verbal bargain, and bind the parties to the performance thereof.

By the civil law, he who recedes from his bargain, loses his *earnest*; or, if the person who received the *earnest* give back, he is to return the *earnest* double. But, with us, the effect of *earnest* is more: the person who gave it is, in strictness, obliged thereby to abide by his bargain; and, in case he decline it, is not discharged upon forfeiting his *earnest*; but may be sued for the whole money disputed. And by 29 Car. II. cap. 3. no contract for sale of goods, to the value of 10*l.* or more, shall be valid, unless the buyer receives part of the goods sold by way of *earnest* on his part, or unless he gives part of

the price to the vender by way of *earnst*, to bind the bargain, &c.

EARNING, or **YEARNING**, a name used in several parts of the kingdom for remitt. See **RUNNET**.

EARTH. See **ENDISH**.

EARTH, *Terra*, in *Natural Philosophy*, one of the four vulgar, or peripatetic elements; denoted a simple, dry, and cold substance; and, as such, an ingredient in the composition of all natural bodies.

It should be well observed, that the element *earth* is a very different matter from the *earth* whereon we tread. Aristotle, having laid down cold and dry as his first element, to give it a suitable name, looked among the diverse bodies for that which should come the nearest thereto; which being *earth*, he gave his first element that denomination; though thus borrowing a word that had been used for a different thing, occasioned a great part of his followers to run into an extravagant error, and to suppose, that this habitable fossil *earth* was an element.

EARTH, in *Chemistry*, is the fourth of the chemical elements, or principles, into which all bodies are resolvable by fire.

After drawing off the spirit, sulphur, and phlegm, and salt, e. gr. of wine, what remains in the retort is a tasteless, scentless, dusty matter, not vapable, either of being raised by distillation, or dissolved by solution; and is called *carb*, or *terra damata*, or *caput mortuum*. See **CAPUT MORTUUM**.

This *carb* is supposed to be the basis, or substratum of all bodies; and that wherein the other principles reside. It is all that is solid, e. gr. in an animal, or vegetable body, i. e. all the real vascular parts; the rest being juices.

There is plainly a subtle *carb*, which may be separated from all animal and vegetable substances, and is the same in all, and is the basis of all. This remains after the separation of the other principles by chemistry, from all animal and vegetable substances, and neither coheres together, nor suffers any change in the fire. The alchemists acknowledge no difference between the *carb* of animals and vegetables; but make their tests for the nicest uses equally of both. If water be poured on these ashes, they acquire some degree of tenacity, so as to become capable of being formed into vessels; but if oil be added, they cohere into a much stronger and more compact mass; hence it should appear, that oil and *carb* are the principles which give consistence and tenacity to plants.

This oil, as well as this *carb*, forms the same in all, and possesses nothing of the poisonous or medicinal virtues of this peculiar plant, they being all separable by decoction, distillation, and other processes of that kind, and not remaining in the caput mortuum, which consists of the *carb*, and this connecting oil. Long drying will divest plants of all their virtues; for that nothing but these principles shall remain in them, these giving solidity and figure, the plant retains its former appearance; but only these remaining, it possesses none of its virtues. Boerhaave's *Chemist.* part ii. p. 21.

To obtain this chemical principle pure and unmixed from the common analysis of vegetables, and other bodies, let the remaining mass, after distillation, be thoroughly calcined, then boiled in several waters, to get out all its salt, and after this dried in a clear fire, or in the sun, and the dried mass will be the pure *carb*. Shaw's *Lectures*, p. 151.

EARTH of dew, an *carb* much valued by many of the chemical experimenters, and prepared in the following manner: a large quantity of dew is to be collected, and set in a wooden vessel, in a cool shady place, covered with a canvas, to keep out dust and flies, there will in three weeks, and sometimes longer, come on a putrefaction in the liquor. During the time of this putrefaction, certain films are daily formed on the surface of the liquor, and these falling down to the bottom, one after the other, form, by degrees, a sediment of a sort of mud. This is to be thrown away, and the dew, when separated from it, is to be filtered clear, and evaporated to a driness, the remainder is a greyish *carb*, which is the true *carb* of dew; this is very light and friable, and is of a foliated structure in the mass, looking like so many leaves of brown paper, spread very thin and even over one another. Phil. Trans. N° 3.

This *carb*, exposed to a smart fire, loses its foliated texture, and runs into a mass, resembling a mixture of salt and brimstone melted together, but it is not at all inflammable. This, ground on a levigating stone, tinges the water to a purplish colour. A pound of this *carb*, properly treated by calcination and elixivation, will yield an ounce of a pure and white salt, somewhat resembling nitre. The chemists have been at great pains to procure this *carb*, but they do not seem yet to have made any very important use of it; and, in all probability, it is no other than that common spar which we know to be contained in all water, and which encrusts the sides of our

tea-kettles, and other vessels, in which water is often boiled. We know, by manifold instances, that spar is rarefiable into vapour with water, and therefore it would be a greater wonder if dew were found not to contain it than that it does.

EARTH, in *Natural History*, is a fossil or terrestrial matter, whereof our globe principally consists. It is either simple, or composed of entirely similar particles; or compound, having a mixture of such as are heterogeneous, as sand, or the like, among them.

Earths are defined to be friable, opaque, insipid bodies; nor inflammable, vitrifiable by extreme heat, diffusable in water, and separable from it by filtration.

The simple *earths* are divided into two orders; and under those, into five genera. Of the first order are those *earths* which are naturally moist, of smooth surfaces, and of a firmer texture; and of the second are those which are naturally dry, of rough dusty surfaces, and of a looser texture. Of the first of these orders, there are three genera, the boles, the clays, and the marles; and of the second there are two, the ochres, and the tripelas, according to Hill's distribution; and chalks according to Da Costa. The several distinguishing characters of which are these.

Of the first order. 1. *Boles* are *earths* moderately coherent, ponderous, soft, not stiff or viscid, but, in some degree, ductile while moist, composed of fine particles, smooth to the touch, easily breaking between the fingers, readily diffusable in water, and freely and easily subsiding from it. See **BOLE**.

2. *Clays* are *earths* firmly coherent, weighty, and compact, very stiff and viscid, ductile to a great degree while moist, smooth to the touch, not easily breaking between the fingers, nor easily diffusable in water, and, when mixed in it, not readily subsiding from it. See **CLAY**.

3. *Marles* are *earths* but slightly coherent, not ductile, stiff, or viscid, while moist, most easily diffusable in water, and by it reduced to a soft, loose, incoherent mass. See **MARLE**.

Of the second order are, 1. *Ochres*. These are *earths* slightly coherent, composed of fine, smooth, soft argillaceous particles, rough to the touch, and readily diffusable in water. See **OCHE**.

2. *Tripelas* are *earths* firmly coherent, composed of fine, but hard, particles, and not readily diffusable in water. M. Da Costa, instead of *tripelas*, substitutes the genus of chalks, which he defines to be *earths* generally hard and dry, harsh and rough to the touch, and readily diffusable in water. See **CHALK**. Hill, of *Fossils*, p. 75. The compound *earths* are a class of fossil bodies, usually confounded with the genuine and simple *earths*, as if substances of the same kind, but being of a very different nature and origin. They are fossils composed of argillaceous and marly particles, separated and divided by adventitious matter, and never found free from those admixtures, or in the state of pure simple marles or clays. Of this class of fossils there are two general orders; those of the one are known by the name of loams, and are composed of sand and clay; and those of the other are called moulds; these are the *earths* that vegetables grow in, and are composed of argillaceous and marly particles, separated by sand, small pebbles, and the grit of stone, and usually intermixed with, and encried by, the putrefied remains of animal and vegetable substances. Of each of these there are several genera. Hill's *Hist. of Fossils*. See **LOAM**, **MOULD**, and **TERRAS**.

The ancient naturalists contented themselves with distributing *earths* according to their uses, into medical *earths*, and such as are used for pottery, painting, and other mechanical purposes. Dr. Woodward, in his *Method of Fossils*, divides *earths* into two classes, viz. those that are smooth or unctuous, subdivided into such as do and do not adhere to the tongue; and those that are dry, harsh, and tough to the touch. Stahl divided them into the calcareous and vitrifiable *earths*. Pott, who is followed by Macquer, into alkaline or calcareous, argillaceous, vitrifiable, and gypsaceous. Linnæus, into ochres, sand, clay, calx, or animal *earth*, and *humus*, or vegetable *earth*. Other authors have enlarged or contracted the number of divisions; for a general account of which, we refer to the tables at the beginning of Linnæus's *Systema Naturæ*, tom. iii. 1770. See also Da Costa's *Fossils*, 119, &c.

See the divers kinds of *earths* described under their proper articles, **BOLE**, **CHALK**, **PUMICE**, **SIGILLATA Terra**, &c.

Naturalists generally rank sand as a species of *carb*, though with no great propriety; sands being, in themselves, a sort of crystals, or little transparent pebbles, calcifiable, and by the addition of a fixed alkaline salt, fusible, and convertible into glass; and therefore properly reducible to the class of stones.

By means of sand it is, that the fatty *carb* is rendered fertile,

fertile and fit to feed vegetables, &c. for pure earth is liable to coalesce into a hard coherent mass, as is clay; and earth thus embodied, and, as it were, glued together, would be very unfit to nourish plants. But if with such earth, sand, i.e. hard crystals, which are indissoluble in water, and still retain their figure, be intermixed, they will keep the pores of the earth open, and the earth itself loose and incompact, and by that means will give room for the juices to move, ascend, &c. and for plants to be nourished thereby. Thus a vegetable planted either in the sand alone, or in the fit globe and earth alone, receives no growth or increase; but is either starved or suffocated; but mix the two, and the mass becomes fertile. In effect, by means of sand, the earth is rendered in some measure organic; by preserving a sort of pores and interstices therein, somewhat analogous to vessels, by which the juices of the earth may be conveyed, prepared, digested, circulated, and at length excreted and thrown off into the roots of plants.

EARTH, animal, belongs to the class of chalks in the above distribution, and consists of shells of animals; or that which is obtained by calcination, or putrefaction of animal substances. To this head we may reduce the earth of the shells of fishes, and of eggs, which have the general properties of calcareous earth; the earth of calcined bones and horns, which are soluble by the nitrous, marine, and vegetable acids, but not capable of being converted into quicklime by calcination, and unsoluble in other fusible mixtures; and the earth of blood, flesh, and skins of animals, which is soluble by all acids, and fusible by fire, but not calcareous.

EARTH, mercurial, is a substance which, according to Becher, and other chemists, enters into the composition of many bodies, chiefly the metallic; together with vitrifiable earth and phlogiston, called by him the inflammable earth. But the existence of this mercurial earth has not yet been satisfactorily demonstrated. Macquer.

EARTHS, vegetable, are distributed by Wallerius into three classes: the first class includes those which are obtained by becoming soft, spongy, and farinaceous plants; they are partly soluble by vitriolic acids, and fusible by fire, more or less, as the plant was more or less nourishing. The second class is had by burning the harder and less succulent plants; this earth is more fusible than the former in nitrous and marine acids, but less soluble in vitriolic acids; it is also fusible by fire. The third class is obtained by burning wood, which is calcareous, and fusible with greater difficulty, as the wood which yielded it is harder; and thus it is found that ashes of the hardest woods make the most unsoluble glass. Swed. Mem. 1760.

EARTH, in Agriculture and Gardening. See SOIL, LAND, &c.

EARTH, untired, the soil, or earth, which is six or seven inches deep, where neither spade nor plough has reached. This is greatly recommended by Mr. Lawrence, for amendments and improvements, both in the fruit and kitchen garden. He assures us, from his own experience, that no kind of compost, made with art, exceeds it; and adds, that if the choicest fruit trees be planted herein, they presently discover an uncommon healthfulness and vigour; and that, if any tender sort of annuals be directly sown in this earth, made fine by sifting, their looks, colour, &c. soon discover that they like the soil. Melons and cucumbers need no other compost, but this untired earth; and asparagus itself will prosper at least as well in this untired earth, if laid a foot and a half deep, as with all the usual expence of dung; though for the tenderer flowers, and exotics, this earth is not found to have any extraordinary excellencies. For annual plants, produced from seed, a coat of this untired earth, two inches deep, may suffice; on other occasions a greater depth is required.

EARTHS of mineral waters. All mineral waters contain earth of some kind, though very different in quantity and in nature. These are found in different waters, of very different colours and appearances, some white, some grey, some yellowish, some reddish, and some brown. They are also as different in their qualities as in their forms; some of them are soluble in acids, others are not so; some fusible in the fire, others not; and some retain their natural colour after burning, others change it in the fire. By this we learn that some are marly, others argillaceous, others ochreous, and some sandy; others there are which are produced by the concretion of certain juices, saline or sulphureous, and others not

so. Some are simply mineral, others are metallic. And as many of these are very different from any of the known earths, even in their pure and dry state, they are yet much less distinguishable when mixed one with another, as they very frequently are in the waters of even our common springs, much more so in the mineral medicinal ones.

The simple infusions of certain sulphureous mineral earths may remarkably alter the waters of wells and fountains, without having any thing of those earths remaining, after their distillation; in the same manner as nothing is separable, by art, from certain liquors, rendered emetic by autumn. The hot mineral waters may contract some alteration from the sulphureous and bituminous matters which they meet with in their course; for these substances all contain soluble salts, which hot water may take up, and carry away with it.

EARTH-tree, *Saxa arbor*, in Persia. See SACKS of

EARTH, and SAND-BAGS.

EARTH-huts, in *Hulbandy*, &c. are a very common fence about London, and its several other parts of England. Where slopes are not to be laid cheap, these are to be preferred to all other fences, both for firmness and duration.

The best manner of making them is this: dig up some turf in a grassy place, a span deep, or nearly to the breadth of the spade, and about four or five inches thick; lay these turfs with the grass outward, even by a line on one side, and on the backside of these, lay another row of turf, leaving a foot space of solid ground on the outside, to prevent the bank from slipping in, if it should be any way faulty. On the outside of this make a ditch, or else let the sides be lowered both ways with a slope two feet deep, and there will be no pasture lost by the fence, because it will bear grass on both sides.

The earth that is dug out of the ditches, or from the slopes, must be thrown in between the two rows of turf till the middle is made level with the rest. Then lay on two or more rows of turf in the same manner, and with more of the earth fill up, and make level as before. Let this method be continued till the bank is raised four feet high, or more, if necessary, only observing, that the higher it is to be carried, the wider the foundation must be made. As the bank is carried up, the sides must not be raised perpendicular, but sloping inward both ways so that at the top it may be about two feet and a half wide. This sort of fence, when made with less care, and faced with clay, is left naked, and serves very well in some places; but when it is thus managed with the turf, the joining of the several pieces are hid in a little time, by the growth of the grassy part of the turf on each side, and it makes a beautiful fence, of as green and pleasant a colour as the rest of the field.

The great improvement upon this plan, is the planting of quicksets, or young white-thorn plants, in the middle of the top of the bank. The earth on each side of these may be raised up with a sort of wall, and the rain that falls wholly preferred for the plants. This plenty of water, and depth of fine earth, make the young plants grow quicker and more vigorously than in any other way; and the most beautiful of all hedges is formed in this manner. When this sort of hedge is young, there must be placed on each side of it a short dry hedge, of about a foot high, to keep the sheep from cropping the young plants; but this may be taken away after a little time.

There is one caution necessary in regard to the making of these banks, which is, that they must never be made a very dry season, because, if much rain should follow, the earth of the bank would swell and burst open, or spoil the shape of the bank; but if this should happen, it is easily enough repaired. This beautiful fence may be made at a smaller price than those unaccommodated to these things may imagine. In good digging ground, where men work for fourteen pence a day, it may be made and planted with quick for two shillings a pole. It may be made proper for the keeping in of deer, only by the small addition of planting, at every eight or ten feet distance, a post a little fluting, with a mortise in it; let this stand about two feet above the bank, and into it mortise all along, put a rail made of a bough of as tree, no deer will ever go over this, nor can they creep under it, as they often do when a pale tumbles down. The quick, on the top of this bank, may be kept clipped and will grow very thick, and afford the best shelter to cattle of any fence in use with us. Mortimer's Hulbandy

EARTH-board, in *Hulbandy*, that part of a PLOW which turns over the earth.

EARTH-flax. See *PLUM ALIUM*.

EARTH-nut, *Arachis*, in Botany, a genus of the *diadelphia dicotyledon* class. Its characters are these: the empancment of the flower opens in two parts; the flower is of the butterfly-kind, and has ten stamina, nine of which coalesce, and the upper one stands off. In the centre is situated an oblong germin, which turns to an oblong pod, containing two or three oblong blunt seeds. We have but one species of this plant, which, it is thought, came originally from Africa, though our settlements in America abound with it, where the negroes cultivate it for food, and eat it both raw and roasted. It multiplies very fast in a warm country; but being impatient of cold, cannot be propagated in the open air in England. Miller.

This plant, with some others of the trifoliate kind, has the property of burrowing its seeds under ground. As soon as the plant is in flower, it is bent towards the ground till it touches it. The point of the flower is then thrust into the ground to a sufficient depth, where it extends itself, and forms the seed-vessel and fruit, which is brought to maturity under-ground. An oil is expressed from the ground-peas, which Sir Hans Sloane maintains to be as good as that of almonds, and which, it is said, may be used, at a very cheap price, for the same purposes, both of food and physic, as the oil of almonds, or olives. Phil. Trans. vol. lix. N^o 52. an. 1769.

EARTH-nut tree. See *CHICKLING NUTCH*.

EARTH-pink. See *PIERISALUTUM*.

EARTH-puceron, in *Natural History*, a name given by authors to a species of puceron very singular in its place of abode. In the month of March, if the turf be raised in several places, in any dry pasture, there will be found, under some parts of it, clusters of ants, and on a farther search, it will be usually found, that these animals are gathered about some pucerons of a peculiar species. These are large, and of a greyish colour, and are usually found in the midst of the clusters of ants. See *PERCEPION*.

The common abode of the several other species of pucerons is on the young branches or leaves of trees; as their only food is the sap or juice of vegetables, probably these *earth* kinds draw out those juices from the roots of the grasses and other plants, in the same manner that the others do from the other parts. The ants that conduct us to these, are also our guides where to find the greater part of the others; and the reason of this is, that as these creatures feed on the farcinate juices of plants, they are evacuated from their bodies in a liquid form, very little altered from their original state; and the ants, who love such food find it nearly prepared for them, in the excrements which these little animals are continually voiding. Reaumur.

EARTH, in *Geography*, this terraqueous globe, or ball, whereto we inhabit, consisting of land and sea.

EARTH, the figure of this, is demonstrated to be nearly spherical. Thus the moon is frequently seen eclipsed by the shadow of the earth; and, in all eclipses, that shadow appears circular, what way soever it be projected, whether towards east, west, north or south, and howsoever its diameter vary, according to the greater or less distance from the earth.

Hence it follows, that the shadow of the earth, in all situations, is really conical, and consequently the body that projects it, i. e. the earth, is nearly spherical.

The natural cause of this sphericity of the globe is, according to Sir Isaac Newton, the great principle of attraction, which the Creator has stamped on all the matter of the universe, and whereby all bodies, and all the parts of bodies, mutually attract one another. And the same is the cause of the sphericity of the drops of rain, quicksilver, &c.

We say it is nearly spherical; for the inequalities on its surface prevent its being perfectly so: besides that, Huygens, and Sir Isaac Newton have shown, that the earth is higher and bigger under the equator than at the poles; so that its figure, nearly, is that of an oblate spheroid, swelling out towards the equatorial parts; and flattened, or contracted, towards the poles.

Though Sir Isaac Newton in his *Principia*, first printed in 1686, had demonstrated, from the theory of gravity, that this must be the real form of the earth, as it revolved about an axis; yet Messrs. Cassini, both father and son, the one in 1712, and the other in 1701, attempted to prove, in the Memoirs of the Royal Academy of Sciences at Paris, that the earth was an oblong spheroid; and in 1718, M. Cassini again undertook, from observations, to show the contrary, or that the longest diameter passes through the poles, which gave occasion for Mr. John Bernoulli, in his *Essai d'une Nouvelle Physique Celeste*, printed at Paris in 1735, to triumph

over the British philosopher, apprehending that these objections would invalidate what Sir Isaac had demonstrated. In 1720, M. de Mairan advanced arguments, supposed to be strengthened by geometrical demonstrations, farther to confirm M. Cassini's assertion. But in 1735 two companies of mathematicians were employed, one for a northern, and another for a southern expedition, the result of whose observations and measurement plainly proved that the earth was flattened at the poles. See *DEGREES*.

Having found that the centrifugal force at the equator is $\frac{1}{230}$ th of gravity, he assumes, as an hypothesis, that the axis of the earth is to the diameter of the equator as 100 to 101, and thence determines what must be the centrifugal force at the equator to give the earth such a form, and finds it to be $\frac{1}{230}$ th of gravity: then, by the rule of proportion, if a centrifugal force, equal to $\frac{1}{230}$ th of gravity would make the earth higher at the equator than at the poles by $\frac{1}{230}$ th of the whole height at the poles, a centrifugal force that is the $\frac{1}{230}$ th of gravity, will make it higher by a proportional excess, which by calculation is $\frac{1}{230}$ th of the height of the poles; and thus he discovered that the diameter at the equator is to the diameter at the poles, or the axis, as 230 to 229. But this computation supposes the earth to be every where of a uniform density; for if the earth is more dense near the centre, then bodies at the poles will be more attracted by this additional matter being nearer; and therefore the excess of the semidiameter of the equator above the semiaxis will be different.

This roundness of the earth is further confirmed, by its having been frequently sailed round: the first time was in the year 1519, when Ferd. Magellan made the tour of the whole globe in 1124 days. In the year 1557, our countryman, Drake, performed the same in 1076 days; in the year 1586, Sir Thomas Cavendish made the same voyage in 777 days; Simon Cordes, of Rotterdam, in the year 1590, and in the year 1598, Oliver Noort, a Hollander, in 1077 days; Wil. Coen. Van Schouwen, in the year 1615, in 739 days; Jac. Hervegins, and Joh. Huygens, in the year 1623, in 802 days; and many others since have performed the same navigation, particularly our own countryman, Lord Anson. All of whom, sailing continually from east to west, at length arrived in Europe, whence they set forth; and in the course of their voyage, observed all the phenomena, both of the heavens and earth, to correspond to, and evince this spherical figure.

Thus, as we go southward the northern stars are depressed, and the southern stars elevated; and the first arrives at the meridian of places that are more easterly, sooner than to the meridian of those towards the west, in proportion to the distance of the meridians measured upon the equator. The same globular figure is likewise inferred from the operation of LEVELLINGS, in which it is found necessary to make an allowance for the difference between the apparent and the true level.

What the earth loses of its sphericity by mountains and valleys, is nothing considerable; the highest eminence being scarce equivalent to the minutest protuberance on the surface of a lemon; what it loses by the swelling of the equatorial parts, on account of the diurnal rotation of the earth on its axis, is more sensible. Huygens determines the ratio of the greater diameter to the less to be as 578 to 577.

Sir Isaac Newton makes the greatest diameter 341 miles longer than the less, fixing the ratio as 602 to 608, or as 230 to 229. If the earth were in a fluid state, its revolution round its axis would necessarily make it put on such a figure, because the centrifugal force being greatest towards the equator, the fluid would there rise and swell most; and that its figure really should be so now, seems necessary to keep the sea in the equinoctial regions from overflowing the earth thereabouts.

The proportion of the equatorial diameter to the polar, as stated by the gentlemen employed on the northern expedition for measuring a DOCK of the meridian, is as 4 to 0.98911; by the Spanish mathematicians as 266 to 265, or as 1 to 0.99624; by M. Bouguer as 179 to 178, or 1 to 0.99441; which Colonel Roy also deduced from collecting the best experiments that have hitherto been made with the pendulum into one view, and applying the equation which the density of the air, in which they severally vibrated, seemed to require; and he observes, that this proportion agrees very nearly with the mean result from the measurement of the degrees of the meridian. Phil. Trans. vol. lxvii. part ii. p. 767.

The following problem, communicated by Dr. Leatherland to Dr. Pemberton, and published by Dr. Robertson, will serve for finding the proportion between the axis and the equatorial diameter, from measures taken of a degree

gree of the meridian in two different latitudes, supposing the earth to be a spheroid, with its axis less than the equatorial diameter.

Let PAE (Tab. II. *Astronomy*, fig. 68.) be an ellipse representing a section of the earth through its axis PA ; the equatorial diameter, or the greater axis of the ellipse, being AA' ; let E and F be two places, where the measure of a degree has been taken; these measures are proportional to the radii of curvature in the ellipse at those places; and H CQ , CR , are conjugate to the diameters, whose vertices are E and F ; CQ will be to CR in the subduplicate ratio of the radius of curvature in E to that in F , by Cor. 1. Prop. iv. part vi. of Moline's Conic Sections, and therefore in a given ratio to one another. Then QV and ZS being drawn parallel to PA , and $QXYW$ parallel to AA' , the angles QCP , RCP are the latitudes of E and F , so that these angles, and the ratio of CQ to CR being given, the rectilinear figure $CQVQXY$ is given in species; and the ratio of $YC' - ZC' = QX - XW$ to $RZ - ZV = QV - XZ$ is given, which is the ratio of CA' to CP ; therefore the ratio of CA to CP is given. Hence, if the sine and cosine of the greater latitude be each augmented in the subduplicate ratio of the measure of the degree in the great latitude to that in the lesser, then the difference of the squares of the augmented sine, and the sine of the lesser latitude, will be to the difference of the squares of the cosine of the lesser latitude, and the augmented cosine, in the duplicate ratio of the equatorial to the polar diameter. Because CQ being taken in CQ equal to CR , and QV drawn parallel to QV , CQ and VQ , CZ and ZR will be the lines and cosines of the respective latitudes to the same radius; and CY , VQ will be the augmentations of CQ and CP in the ratio named. Then, in order to find the ratio between the two axes of the earth, let L denote the greater, and F the lesser of the two latitudes, M and N the respective measures taken in each, and let O denote $\sqrt{\frac{M}{N}}$.

And $\sqrt{\frac{L^2 - F^2 \times L \times F}{O^2 \times L \times F - E^2 \times F}}$ is = lesser axis
greater axis

It also appears by the above problem, that if one of the degrees measured is at the equator, the cosine of the latitude of the other being augmented in the subduplicate ratio of the degrees, the tangent of the latitude will be to the tangent answering to the augmented cosine in the ratio of the greater axis to the lesser. For supposing the place out of the equator to be E ; if the semicircle $PEmnp$ be described, and IC joined, and ma drawn parallel to CA ; Cc is the cosine of the latitude to the radius CP ; and CY that cosine augmented in the expressed ratio YQ being to YI , i. e. Cc to Cn , or CP , as the tangent of the angle YQC , the latitude of the point E , to the tangent of the angle YCI , belonging to the augmented cosine. Thus if M represent the measure in a latitude denoted by E , and N the measure at the equator, let A denote an angle, whose measure is $\sqrt{\frac{M \times E}{N}}$, E . Then $\frac{A}{E}$ is = lesser axis
greater axis. But M ,

or the length of a degree, obtained by actual measurement in different latitudes, is known from the following table.

	Toises
Maupeirtuis and associates in lat.	66 20 found $M = 57438$
Cassini and de la Caille	49 22 $M = 57074$
Boscovich	45 0 $M = 57050$
De la Caille	43 0 $M = 56972$
Juan and Ulloa	33 18 $M = 57037$
Bouguer	$M = 56768$
De la Condamine	At the Equator $M = 57552$
	$M = 56749$

By comparing the first of these measures with each of the following, the second with each of the following, &c. by the problem, and its corollary, we shall obtain twenty-five results, shewing the relation of the axes or diameters; and from the arithmetical means of the several comparisons, we shall have the ratio of the greater axis to the lesser as 1 to 0.9940888; or as 1 to 0.99457308 or as 1 to 0.9952621; or as 1 to 0.9971818; or as 1 to 0.9947821; and from the mean of all of them as 1 to 0.9951089. If the measures of the latitudes of $49^\circ 22'$, and of 45° , which fall within the meridian line drawn through France, and which have been re-examined and corrected, since the northern and southern expedition, be compared with those of Maupeirtuis and his associates in the north, and that of Bouguer at the equator, the ratio of the greater axis to the less will be reduced to the following viz. as 1 to 0.9919994; 1 to 0.99337; 1 to 0.9952717; 1 to 0.9987542; 1 to 0.9987698; and

1 to 0.9965152; the arithmetical mean of which ratios, or that of 1 to 0.9953167, may be taken for the ratio of the greater axis to the less; which is as 330 to 228.92074, nearly the same with that assigned by Sir Isaac Newton. Add, that experiments made on pendulums, which must be of different lengths, to swing equal times here and at the equator, evince the same thing. Thus, a pendulum must be 2.33 lines shorter at the equator than at the poles.

Mr. de la Hire, and Dr. Derham, indeed, have shewn, that this diversity may arise, either from the greater heat, or the greater rarities of the air there than here; as having observed a like variation between pendulums, when heated, and cold; and when in vacuo, and open air. But, besides that Sir Isaac Newton, and M. Bernoulli, have set aside these causes, as insufficient, it has been found, by actual measurement, that the degree of a meridian grows larger, the further we go towards the line; which puts the spheroidism of the earth beyond question. The ancients had various opinions as to the figure of the earth; some, as Anaximander, held it cylindrical; and others, as Leucippus, in form of a drum. But the principal opinion was, that it was flat; that the visible horizon was the bounds of the earth, and the ocean the bounds of the horizon; that the heavens and earth above this ocean were the whole visible universe; and that all beneath the ocean was hutes; of which opinion were not only divers of the ancient poets and philosophers, but also some of the Christian fathers, as Lactantius, St. Augustine, &c.

It is evident from the above pretty conclusions from the spherical figure of the earth, &c. That if any part of the surface of the earth were quite plain, a man could no more walk upright thereon, than on the side of a mountain. 2. That the traveller's head goes a greater space than his feet; and a horseman that, a footman, as moving equal arches of greater circles. 3. That a vessel, full of water, being rolled perpendicularly, some of the water will be continually flowing out, yet the vessel will remain full; and, on the contrary, if a vessel full of water be let perpendicularly down, though nothing flow out, yet it will cease to be full; consequently, there is more water contained in the same vessel at the foot of a mountain, than on the top; because the surface of the water is compressed into a segment of a less sphere below than above. Two, Astronom. lib. 1. cap. 2.

EARTH, changes of the. Mr. Boyle supposes there are great, though slow internal changes, in the mass of the earth. He argues from the varieties observed in the change of the magnetic needle, and from the observed changes in the temperature of climates. But as to the latter, we doubt whether he could have drawn the weather sufficient to direct his judgment. Boyle's Works art. vol. 1. p. 202, 203. See ABSORPTIONS of the earth.

EARTH, magnetism of the. The notion of the magnetism of the earth was started by Gilbert, and Mr. Boyle supposes magnetic effluvia moving from one pole to the other. See Works art. vol. 1. p. 285, 290.

Dr. Knight also thinks, the earth may be considered as a great loadstone, whose magnetic parts are disposed in a very irregular manner; and that the south pole of the earth is analogous to the north pole in magnets, that is, the pole by which the magnetical stream enters. See MAGNET.

He observes, that all the phenomena attending the direction of the needle, in different parts of the earth, in great measure correspond with what happens to a needle, when placed upon a large terella; if we make allowances for the different dispositions of the magnetic parts, with respect to each other, and consider the south pole of the earth to be a north pole, with regard to magnetism. The earth might become magnetical by the iron ores it contains, for all iron ores are capable of magnetism. It is true, the globe might notwithstanding have remained unmagnetical, unless some cause had existed capable of making that repellent matter producing magnetism move in a stream through the earth.

Now the doctor thinks that such a cause does exist. For if the earth revolves round the sun in an ellipse, and the south pole of the earth is directed towards the sun, at the time of its descent towards it, a stream of repellent matter will thereby be made to enter at the south pole, and come out at the north. And he suggests, that the earth's being in its perihelion in winter may be one reason why magnetism is stronger in this season than in summer. This cause here assigned for the earth's magnetism must continue, and perhaps improve it from year to year. Hence the doctor thinks it probable, that the earth's magnetism has been improving ever since the creation, and that this may be one reason why the use of the compass was not discovered sooner. See Dr. Knight's Attempt to demonstrate, that all the Phenomena in Nature may

E A R

may be explained by Attraction and Repulsion, prop.
37.

EARTH, the *globe of life*, and the *numbers of miles* its diameter contains, have been variously determined by various authors, ancient and modern. The way to arrive at it is, by finding the quantity of a degree of a great circle of the *earth*; but this degree is found very different, according to the different methods and instruments made use of, as well as the different observers. The method observed by Mr. Norwood, and the French astronomers, Picard, Cassini, &c. viz. by measuring the distance between two remote places on the same meridian, is undoubtedly the best, and was performed with great accuracy, especially by M. Cassini, and since by others. See **DEGREE**, of *latitude*. According to that author, the *amplitude* or circumference of the *earth*, is 12357020 Paris feet, or 123659977 English feet, or 25311 of our statute miles; by which, supposing the *earth* spherical, its diameter must be 7964 statute miles; and consequently its *radius*, or *semidiameter* may be taken in a round number, for 20000000 feet its surface will be 100044436 miles² which, being multiplied into $\frac{1}{2}$ of its *semidiameter*, gives the solid content of the *globe of the earth* 285600000 cubic miles. These several dimensions are greater or less, according to the assumed measure of a degree. Cassini adopted Picard's measure of 57066 toises. But the magnitude, as well as the *FIGURE of the earth*, may be deduced from the preceding problem. For, as half the *latitudinal* of the greater axis *A*, (Tab. II. Art. 68.) is the *radius of curvature* in *A*, it is given in magnitude from the degree measured there, and thence we shall have the axes themselves. Thus, the circular arch equal to the radius being 57,29578 degrees, if this number be multiplied by 50535 toises, the measure of a degree at the equator, as Bouguer has stated it, we shall have the *radius of curvature* there, or half the *latitudinal* of the greater axis; and this is to half the *lesser axis* in the ratio of the *lesser axis* to the greater, i. e. as 0,9952367 to 1: whence the *lateral femina* will be 3366910 toises, and the greater 3228118.

From the same problem and figure it appears, that if an angle be taken, whose tangent shall be to the tangent of either latitude, as the lesser axis to the greater, the measure of a degree in that latitude will be to the measure of a degree at the equator, in the triplicate ratio of the cosine of this angle to the cosine of the latitude, *e. pr.* If *E* be one of the places measured, the tangent of the angle *Y C*, will be to the tangent of *Y Q*, the latitude of *E*, as *Y* to *Y Q*, *i. e.* as the lesser axis to the greater; and *Q C* : *C* : *S*, *C* / *S*, *C* / *Y* : *C* / *Q* : *cof. Y C* : *cof. Y Q* ; but by the property of the ellipse, *Q C* : *C* : *P* : *C* / *P* : the radius of curvature in *E* to the radius of curvature in *A*, *i. e.* as the measure of a degree in *E* to the measure of a degree in *A*. Therefore, if *M* represents the measure in a latitude *B*, and *N* the measure at the equator; and an angle *A* be found, so that *t*, *A* may be = $\frac{\text{lesser axis}}{\text{greater axis}} \times A$, *B*, *N* will be

$\approx M \div \text{cube } \frac{4}{3} \frac{V}{\pi}$; and hence the axes may be known as above. Thus from the fix ratios between the axes already found, see *Figure of the Earth*, we may obtain nine values of the axes, by comparing each ratio with both of its respective latitudes and measures; and the means will be, for the greater femiaxis, 3276473 toises; and for the lesser, 3263993; and these, proportioned again by the mean ratio of the axes above stated, and by their assigned fix ratios will give, for the greater femiaxis, 3279328 French toises, and for the lesser femiaxis, 3263298; and aligning 6 Paris feet to a toise, the proportion of the English foot to the French, as 107 to 114, the greater femiaxis will be 3265863 English toms, or, dividing by 820, the number of 18 fms. in an English mile, 3982.538 miles; and the lesser femiaxis 3267060 fathoms, or 3951.824 miles; and the greater axis, or equatorial diameter, equal to 7940.536 miles, and the lesser, or polar diameter, equal to 7933.648 miles; so that the equatorial diameter is about 46,918 miles longer than the polar or *cardi's* axis. See farther on this subject, Suite des Mem. de l'Acad. R. ann. 1718, p. 247. Maclearius's Fluxions, vol. ii. book i. ch. 14. Robertson's Navigation, book viii. sect. 8.

On the surface of the earth are conceived the fine circles as on the surface of the mundane sphere elsewhere described, viz., an EQUATOR, ECLIPTIC, TROPICS, POLAR CIRCLES, MERIDIANS, HORIZON, PARALLELS, &c. which see; as also SPHERE and GLOBE. The seas and unknown parts of the earth, by a measurement of the best maps, contain 106,220,226 square miles; the inhabited parts, 38,990,805; Europe, 4,450,005; Asia, 17,688,243; Africa, 9,954,807; America, 14,110,874; in all, 199,512,959.

E A R

which is the number of square miles on the whole surface of our globe.

The terrestrial globe is now generally granted to have two motions, besides that on which depends the PANGLOSSION of the equinoxes, the one DUTURAL, around its own axis in the space of 24 hours, which constitutes the natural day or nycthemeron. The other annual, round the sun, in an elliptical orbit or track, in 365 days, 6 hours, constituting the year.

From the former we derive the diversities of NIGHT and DAY. And from the latter the vicissitudes of seasons, spring, summer, &c.

See the motion of the *earth* proved, under EARTH is *astronomy*.

on the terraqueous globe we distinguish three parts, or regions, viz. 1. The external part or crust, which is that from which vegetables arise and animals are nourished. 2. The middle, or intermediate part, which is possessed by fossils, extending further than human labour ever yet penetrated. 3. The internal, or central part, which is unknown to us, though by many others supposed of a magnetic nature; by others, a mass or sphere of fire; by others an abyss, or collection of waters, surrounded by the strata of earth; and by others, a hollow empty space, inhabited by animals, who have their fun, moons, planets and other conveniences within the fame: others divide the body of the globe into two parts, viz. the external part, which they call the cortex, including the whole depth or mass of the strata of the earth; and the internal, which they call the nucleus, being of a different nature from the former, and possessed by fire, water, or the like.

The external part of the globe either exhibits inequalities, as mountains or vallies; or it is plain and level; or dug in channels, fissures, beds, &c. for rivers, lakes, seas, &c.

These inequalities in the face of the *earth* are, by most naturalists, supposed to have arisen from a rupture or subversion of the *earth*, by the force either of the subterraneous fires or waters. The *earth*, in its natural and original state, Des Cartes, and after him, Buxtorf, Steno, Woodward, Whillel, and others, suppose to have been perfectly round, smooth, and equable; and they account for its present rude and irregular form principally from the great deluge. See DELUGE.

In the external, or cortical part of the earth, we meet with various strata, which are supposed to be the sediments of various floods; the waters wheateer, being replete with matters of divers kinds, as they dried up, or oiled through, deposited these different matters; which in time hardened into strata of stone, sand, coal, clay, &c.

Dr. Woodward has considered the subject of these strata with great attention, viz. their order, number, thickness, with respect to the horizon, depth, interpositions, figures, colour, confidence &c. He ascribes the origin and formation of them all, to the great flood or cataclysmus. At that terrible revolution, he supposes the terrestrial bodies of all kinds to have been dissolved and mixed with the waters, and sustained therein, so as only to constitute one common mass therewith. This mass of terrestrial principles, intermixed with water, he supposes to have been at length precipitated to the bottom, and that generally, according to the laws of gravity, the heaviest sinking first, and the lighter in their order. By such means were the strata formed, whereof the *earth* consists, which, amidst their solidity and hardness by degrees, have continued to ever since. These sediments, he further concludes, to have been at first all parallel and concentrical; and the surface of the *earth* formed thereby, perfectly smooth and regular; but that, in the course of time, divers changes happening, from various causes, namely, the *earth*'s contraction, the *earth* was disturbed and broken, and the surface of the strata by such means brought to the irregular form in which it now appears. Mr. de Buffon supposes that the *earth*, as well as the other planets, are parts struck off from the body of the sun by the collision of comets; and that when the *earth* assumed its form, it was in a state of liquefaction by fire. See further particulars under DELUGE.

EARTH, in *Astronomy*, is one of the primary planets, according to the system of Copernicus. Its character is ☉.

In the hypothesis of Ptolemy, the *earth* is the centre of the system.

Whether the earth move, or remain at rest, i. e. whether it be fixed in the centre, with the sun, heavens, and stars moving round the same from east to west; or whether the heavens and stars being at rest, the earth moves from west to east, is the great article that distinguishes the Ptolemaic from the Copernican system.

EARTH,

EARTH, motion of. The happy industry of the astronomers of our age has put the mobility of the earth beyond all reasonable doubt; on which account, the names of Copernicus, Galileus, Kepler, Hook, Flamsteed, Bradley, &c. will ever be mentioned with the highest honour.

Indeed, the same motion had been held by many of the ancient philosophers. Cicero, in his *Tuſc. Quæſt.* affirms us, that Nicetas of Syracuſe firſt diſcovered that the earth had a diurnal motion, by which it revolved round its axis in the ſpace of 24 hours; and Ptolemy, de *Placit.* Philoſoph. tells us, that Philolaus diſcovered its annual motion round the ſun; and about 200 years after Philolaus, Ariſtarchus, the Samian, propoſed the motion of the earth in ſtronger and clearer terms, as we are aſſured by Archimedes in *Arenar.*

But the religious opinions of the heathen world prevented the doctrine's becoming more cultivated. For Ariſtarchus being accuſed of ſacrilege by Cleonides for moving Vella and the twelve deities of the univerſe out of their places, the philoſophers began to lay aſide fo perilous a poſition.

Many ages afterwards, Nic. Cuſanus revived the ancient ſyſtem, in his *Doct. de Pignorant.* and affirmed the motion of the earth; but the dogma gained very little ground till the time of Copernicus, who ſhewed its great uſe and advantages in aſtronomy; and who had immediately all the philoſophers and aſtronomers who dared to differ from the crowd, and were not afraid of eccleſiaſtical cenſures, on his ſide. So that Kepler, his contemporary, made no ſeuple to exclaim, *Hædians timore præſtantiffimæ quique philoſophorum & aſtronomorum Copernici adhibentur ſeſſio qd hæc placita; quinimo ſuffragantur melioribus: cæteris poro ſola abſtat ſuperſtitio, aut intus & Clamibular.* See **COPERNICAN.**

The arguments alleged againſt the motion of the earth are weak and frivolous. Such are,

1. That it is a heavy body, and very unfit for motion.
2. That if the earth were to move round its axis in 24 hours, all our houſes, buildings, &c. would tumble down.
3. That bodies would not fall upon the places perpendicularly under them; nor could a bullet, e. g. ſhoot perpendicularly from the ground, fall back again upon the ſame ſpot.
4. That it is contrary to the words of ſcripture. And
5. That it is repugnant to our ſenſes, which repreſent the earth at reſt, and the ſun in motion.

But the principal argument againſt the annual motion of the earth, is the want of an annual parallax in the fixed ſtars. For let *T A T* (*Tab. II. fig. 69.*) repreſent the earth's orbit about the ſun *S*, *T X* the axis of the earth, and *t x* parallel to *T X*, will repreſent the poſition of the ſame axis at the oppoſite point *t*. Suppoſe *T X* to be directed towards the ſtar *P*, and it is manifeſt, that the axis of the earth will not be directed to the ſame ſtar, when it comes to the ſituation *t x*, but will contain an angle *x P t* with the line *P t*, joining the earth and ſtar, equal to the angle *P T t*, under which the diameter *T t* of the earth's orbit appears to a ſpectator, viewed from the ſtar *P*. It might be expected, therefore, that by obſerving the fixed ſtar *P*, from the different parts of the earth's orbit, we might judge of the angle *T P t*, and conſequently of the proportion of *T P*, the diſtance of the ſtar to *T t*, the diameter of the earth's orbit, or double diſtance of the ſun. Yet it is certain, that aſtronomers have not hitherto been able to diſcover any difference in the apparent ſituation of the fixed ſtars with reſpect to the axis of the earth, or to one another, that can ariſe from the motion of the earth: though, ſince the reſtoration of the Pythagorean doctrine of the earth's motion, they have taken great pains to examine the matter.

The ſeeming motion of the pole-ſtar, obſerved by Mr. Flamſteed, was by ſome miſtaken for a proof of its annual parallax; but this phenomenon has ſince been accounted for in the moſt ingenious manner by Dr. Bradley, from the motion of light combined with that of the earth in its orbit. See **PARALLAX** and **LIGHT**.

The objection to the earth's motion, from there being no diſcernible parallax of the fixed ſtars, is answered by obſerving, that the diſtance of the fixed ſtars is ſo great, that the diameter of the earth's orbit bears no ſenſible proportion to it; ſo that the parallax is not to be diſcovered by our exiſtent inſtruments. Nor is this immenſe diſtance of the fixed ſtars advanced by the Copernican merely as an hypotheſis for the ſake of ſolving the objection. For there ſeems great reaſon to ſuppoſe the fixed ſtars like to our ſun, and hence to conclude their diſtance to be vaſtly great, ſince they appear to us with ſo faint a light, and of no ſenſible diameter, even in the largeſt teleſcopes.

VOL. II. N^o. 106.

But from the diligence and accuracy of late aſtronomers, we learn ſeveral curious things in confirmation of the motion of the earth about the ſun, and ſerving to ſolve this only material objection againſt it. See **LIGHT**.

The arguments for the motion of the earth are of a different kind to the objections againſt it, and carry other ſort of evidence with them, being deduced from actual obſervation and phenomena, and not from the fanciful ſaricaſms of timorous zealots. They are theſe, 1. The ſun will equally appear in motion, and the earth as ſtanding ſtill, to a ſpectator on the earth, whether the ſun really move round the earth at reſt, or the earth move round the ſun at reſt.

For ſuppoſe the earth in *T* (*Tab. Aſtronom. fig. 15. N^o. 2.*) and the ſun in *s*; the ſun will then appear in *T*. And, ſuppoſe the ſun to proceed in an orbit ſurrounding the earth from *s* to *2*, he will then appear in *s*; and, if he proceed farther to *3*, he will ſeem in *2*; and ſo this will be appear to go on, according to the order of the ſigns in the ecliptic. Suppoſe, again, the earth in *s*, and the ſun in *T*, the ſun will now be ſeen in *s*; let the earth go on from *s* to *2*, the ſun will appear to the inhabitants of the earth to have proceeded from *s* to *m*; and if the earth proceed to *3*, the ſun will appear to have advanced farther from *m* to *2* and ſo on, according to the ſucceſſion of the ſigns of the ecliptic.

Thus does the ſun appear alike to move, whether he really move or ſtand ſtill; ſo that the objection from ſenſe is of no force. But again,

2. If one of the planets be ſuppoſed to have moved a certain ſpace from weſt to eaſt, the ſun, earth, and other planets, together with the fixed ſtars, will all ſeem to an inhabitant of that planet to have moved juſt to far round the contrary way.

For, ſuppoſe a ſtar *M* (*fig. 16. N^o. 2.*) in the zenith of an inhabitant of a planet placed in *P*; and ſuppoſe the planet to have revolved on its axis from weſt to eaſt, in a certain ſpace of time the ſun *S* will have arrived at the zenith of *P*, then the ſtar *I*, then *N*, then the earth *E*, and at length the ſtar *M* again. To the inhabitant of the planet, therefore, the ſun *S*, with the earth *E*, and the ſtars *I*, *N*, *M*, &c. will appear to have moved round the planet a contrary way.

Thus, to the inhabitants of the planets (if any ſuch there be) the mundane ſphere, with the ſun, ſtars, and all the other planets, will as to us, appear to move round them from eaſt to weſt; and accordingly, the inhabitants of our planet, the earth, are only liable to the ſame deluſive appearances with thoſe of the reſt.

3. The orbits of the planets include the ſun as the common centre of them all, but they are only the orbits of the ſuperior planets that include the earth, which, however, is not in the centre of any of them, as is ſhewn under **SUN** and **PLANET**.

4. The earth's orbit being proved to be between thoſe of Venus and Mars, it follows, that the earth muſt turn round the ſun: for as it lies within the orbits of the ſuperior planets, their motion would appear unequal and irregular; but they would never either be ſtationary or retrograde without this ſuppoſition.

5. From the orbits and periods of the ſeveral planets about the ſun, and of the moon and ſatellites round the earth, Jupiter and Saturn, it is evident, that the law of gravitation is the ſame towards the earth, Jupiter, and Saturn, as towards the ſun: and the periodical times of the ſeveral bodies moving around each, are in the ſame ratio to their ſeveral diſtances from them.

Now it is certain, that, on the hypotheſis of the earth's annual motion, her periodical time exactly ſuits this law, bearing ſuch a proportion between thoſe of Mars and Venus as the ſeveral other bodies directed by the ſame law do bear; i. e. the ſquares of the periods are, in all, as the cubes of the diſtances from the centre of their orbits. But ſuppoſing the earth too at reſt, this law is broken moſt exorbitantly.

For, if the earth does not move round the ſun, the ſun muſt move with the moon round the earth: now, the diſtance of the ſun to that of the moon being as 27754 ſemidiameters of the earth to 60, or nearly as 306 to 1; and the moon's period being leſs than 28 days, the ſun's period ſhould be found no leſs than 212775 days, or 583 years; whereas, in fact, it is but one year. Which might conſideration Mr. Whiſton thinks of weight enough to determine the controverſy between the two ſyſtems, and to eſtabliſh the motion of the earth for ever.

Whereas, ſuppoſing our earth to have once revolved about the ſun in a circular orbit, whole ſemidiameter were equal to the earth's original diſtance from the ſun fix degrees paſt its perihelion, the annual period would be found exactly and ſurprizingly equal to the lunar or the ancient ſolar year, which were exactly commensurate.

rate, containing 12 synodical, or 13 periodical months, i. e. 365 days, 4 hours, 19 minutes.

6. The distances of certain of the fixed stars from the zenith have been observed to be various at various times of the year. That particularly of the pole-star from the pole, has been discovered by Mr. Flamsteed from repeated observations, for seven years successively, to be greater about the summer solstice than about the winter, by about 40 seconds. Whence it appears, that the earth changes its situation, receding from the pole-star, and returning back to it again annually.

Which argument is farther confirmed from this, that the earth is nearer the sun at Christmas than at Midsummer; as appears, both from the sun's apparent diameter being greater in December than in June; and from its motion being swifter, by one twenty fifth part in the former season than the latter, whence it is, that there are about eight days more in the summer half year, viz. from March to September, than in the winter, from September to March.

7. Either the heavenly bodies revolve round the earth in 24 hours, or the earth revolves round its axis in that time. Now, the planets revolving round the sun, perform their revolutions in greater or less times, as their orbits are greater or less, i. e. as they are more or less remote from the sun. Of consequence, if the stars and planets revolved round the earth, they would perform their revolutions in unequal times, according as their orbits or their distances were unequally big. At least, the fixed stars, which are at such prodigious distances from the earth, would never move round it in 24 hours, as the nearest planet is supposed to do.

This is an inconceivable, which is avoided in the system where the earth is supposed to move; and where every planet is so much the longer in describing its annual orbit round the sun as that orbit is greater.

8. In all the works of nature with which we are acquainted, the Creator appears to act by the shortest, easiest and simplest means. Now, if the earth be at rest, and the stars move, the velocity of these latter must be immense; and yet all the purposes thereof might have been answered by a moderate motion of the earth alone.

For the moon's distance from the earth amounts to 240,000 miles. Hence, the circumference of the moon's diurnal circle being 1,507,058 feet miles, the moon's diurnal motion must be 628 12 miles full of 2200 miles, which is really the case; consequently, in each second, a space less than that of the pulse of an artery, the moon, though the flower of all the heavenly bodies, must move more than 17 miles. Again, the sun's mean distance from the earth is 237,500 femidiameters of the earth, or 55,000,000 miles; consequently the sun's diurnal path, when in the equator, must be 550,640,000 miles; and therefore, in the space of one second, i. e. in the twinkling of an eye, he must move more than 6008 miles.

Again, the distance of the sun from the earth is to that of Mars, supposing the earth, and not the sun to be the centre of the system, nearly as one and a half; to that of Jupiter, as one to five and a quarter; and to that of Saturn, as one to nine; wherefore, at the diurnal space, and all other things described in the same time, are in the same ratio, Mars, in one twinkling of an eye, must fly 10,364, Jupiter 36,000, and Saturn 621 12 miles. Lastly, the fixed stars being yet vastly more remote from the earth than Saturn, their motion in or near the equator must be vastly swifter than that of Saturn.

9. If the earth be at rest, and the stars move by any common motion, the several planets must each day describe several spirals turning forth to a certain term towards the north, and thence returning to the opposite term towards the south, sometimes narrower and sometimes broader.

For the distances of the several planets from the zenith alter every day, increasing to a certain point towards the north, and thence decreasing again towards the south. Consequently, the altitude of the pole being always found the same, and the planets not returning to the same point of the meridian, they do not describe circles, but spirals. Add, that as the several planets do not retain the same distance from the earth, but are sometimes nearer, and sometimes recede farther from it, at a greater distance, a greater spiral, and at a less, a less is described.

Further, as their motion is slower when the planet is farther from the earth, the greater spirals are described in less time than the lesser; and as the greatest and least distance of the planets from the earth is not affixed to the same point of the heavens, the planets have moved in different parts every day from the beginning.

Besides, the force by which the stars and planets revolve in their orbits are not directed to the centre of the earth, but

to the centres of the several orbits which they describe, or to innumerable imaginary points in the axis of the earth; and these forces tending to different and continually varying centres must likewise increase exactly in proportion to the distances from the axis; whereas the force of attraction is found to decrease.

10. Bodies let fall from any considerable height, are found by experiment, not to fall upon the spot perpendicularly under them, but to the south-east thereof.

The experiment was proposed to Dr. Hook in the year 1679, by a person who suggested, that, if the earth had any diurnal motion, the body would fall to the east of the perpendicular. Dr. Hook, on that occasion, read a discourse before the Royal Society, wherein he endeavoured, *a priori*, to shew that curve a falling body would describe; asserting, particularly, that the fall of the body would not be directly east, but south-east; which was confirmed by divers actual trials. The objection which supposes, that e. g. a ball fired perpendicularly upward in the air should fall westward of the place from which it was projected, on the supposition of the earth's revolution eastward, can have no weight, when it is considered that the gun and ball partake of the earth's motion; and therefore, being carried forward with the air as quick as the earth and air turn, it must fall down on the same place, describing in its descent the diagonal of a parallelogram, whose two sides are proportional to the forces acquired from the earth's motion and the gravity of the ball. Thus a stone let fall from the top of a main-mast, if it meets with no obstacle, falls on the deck as near the foot of the mast when the ship sails as when it does not.

11. The power of gravity is found to decrease as you approach nearer to the equator, which is a circumstance that agrees to all bodies which have a motion on their axis, and to them only, as being really the necessary result of such motion.

For a body, revolving on its axis, the parts or appendages thereof are continually endeavouring to recede from the centre. Consequently, the equator being a great circle, and the parallels all decreasing towards the poles the centrifugal force is greatest in the equator, and decreases towards the poles in the ratio of the diameters of the parallels to that of the equator. Now the power of gravity determines the several parts or appendages towards the centre of the whole; consequently, the centrifugal force, acting contrary to the power of gravity, retards the descent of bodies, and that most where it is greatest.

Dr. Keil computes, that the force of gravity to the centrifugal force at the equator is as 289 to 1; consequently, a body placed there, would lose one 288th part of the weight it would have were the earth at rest; consequently, the centrifugal force at the poles being infinitely small, a body will there weigh 289 pounds, which at the equator only weighs 288.

12. The following is an actual demonstration of the earth's motion, drawn from physical cause, for which we are indebted to the discoveries of Sir Isaac Newton, and which Dr. Keil takes for conclusive and unanswerable.

All planets, it is demonstrated, gravitate towards the sun; and observations testify so, viz. either that the earth turns round the sun, or the sun round the earth, in such a manner as to describe equal areas in equal times. But it is demonstrated farther, that wherever bodies turn round each other, and regulate their motions by such a law, the one must of necessity gravitate to the other; consequently, if the sun in its motion doth gravitate to the earth, then or is to be equal and contrary, the earth must likewise gravitate towards the sun.

Again, the same author has demonstrated, that when two bodies gravitate to one another, without directly approaching one another in right lines, they must both of them turn round their common centre of gravity; the sun and earth, therefore, do both turn round their common centre of gravity; but the sun is so great a body in respect of our earth, which is, as it were, but a point; that the common centre of gravity of the two bodies will lie within the body of the sun itself, and not far from the centre of the sun. The earth, therefore, turns round a point, which is the body of the sun, and therefore it turns round the sun. Q. E. D.

13. B. tides, if the sun moves about the earth, the earth's attractive power must draw the sun towards it from the line of projection, so as to bend its motion with a curve; but the sun being at least 227000 times as heavy as the earth, it must more 227000 times as slowly towards the earth as the earth does towards the sun; and consequently the earth would fall to the sun in a short time, if it had not a very strong projectile motion to carry it off.

There

There is indeed no such thing in nature as a heavy body moving round a light one as its centre of motion. A pebble, as Mr. Ferguson familiarly illustrates this matter, fallen to a mill-stone by a firing, may, by an easy impulse, be made to circulate round the mill-stone; but no impulse can make a mill-stone circulate round a loose pebble, for the mill-stone would go off and carry the pebble along with it.

14. Dr. Bradley, late astronomer royal, has found, by a long series of the most accurate observations, that there is a small apparent motion of the fixed stars, occasioned by the observation of their light, and so exactly answering to an annual motion of the earth, as evinces the same even to a mathematical demonstration. See *LUCKY*.

To say no more; to suppose the earth, at rest, confounds and destroys all the order and harmony of the universe, annuls its laws, and sets every part at variance with each other, robs the Creator of half the praise of his work, and mankind of the pleasure of the contemplation thereof. In effect, it renders the motions of the planets inexplicable and useless, which otherwise are plain and simple. So that such of the later astronomers, as have asserted it with the most zeal, have been forced to set it aside, when they came to compute the motions of the planets. None of them would ever attempt to compute these motions in variable spirals; but in all their theories they tacitly suppose the earth to move on its axis, so as to turn the diurnal spirals into circles.

Thus, the Jesuit Ricciolus, though he, at the pope's command, opposed the motion of the earth with all his might, as something contrary to holy scripture; yet, to frame astronomical tables, which should tolerably agree with observation, he was forced to have recourse to the motion of the earth as his only refuge.

This, De Chales, another of the same fraternity, frankly confesses: "P. Ricciolus—*minus parvitas optare potuit, quæ ad vindicandæ observationum respondentem, nisi secundum systema terra mota*; notwithstanding that he called in "all the foreign and noted assistants of moveable epicycles, to that in his Astronomia Reformata, where he undertakes to give accurate tables of the celestial motions, he gives into the hypothesis of the motion of the earth." De Chales Astron. Reformat. lib. x. cap. 1. See *COPERNICAN*.

The system then, which supposes the earth at rest, is of itself of no use or significance in astronomy; nor does it avail more in physics; for the principal phenomena are no way deducible from it; but the remainders of it are either forced to fly to the immediate agency of the Deity (which in physics is the same as the *adulatio ad absurdum in Geometry*) or to reasons and principles unknown.

Some oppose the motion of the earth as contrary to revelation; these being mention made in holy scripture of the sun rising and setting, of his standing still in the time of Joshua, and his going back to that of Hezekiah.

Now, to take the genuine sense of these passages, the laws of interpretation must be settled. Is then, we suppose, that the several words of scripture have their several ideas corresponding to them; and that a man takes their sense, in whom those ideas are excited by the reading. 2. That the words of scripture, attentively read, are sufficient to excite those ideas in a mind not prepossessed. Hence, 3. It follows, that either God must have exhibited the definitions of the words that occur in scripture; or, that he supplies prior notions, and leaves us to take their sense in the ordinary way. Hence, 4. We argue, that no other ideas are to be affixed to the words of scripture, but such as occur to a person who looks or attends to the things themselves spoken of.

By the sun's rising, therefore, is meant no more than his re-appearance in the horizon, after he had been hid below it; and, by his setting, an occultation of the sun, which was before visible in the horizon. When the preacher therefore says, *Ecclesi. 1. 5. The sun also ariseth, and the sun goeth down, and hasteth to his place where he ariseth*, he means, doubtless, no more than that the sun, which before was hid, is now seen in the horizon; and after being there conspicuous, is hid again, and at length re-appears in the east. For thus much only appears to a person who views the sun; and therefore thus much, and no more, is expressed by the sacred writers.

In like manner, when in *John. x. 12, 13*, the sun and moon are said to have stood still, all meant by station is, that they did not change their place with respect to the earth. But that generally, by *Sun*, stand thou still upon Gibeon, and thou moon, in the valley of Ajalon, required no more, than that the sun, which then appeared over that city, should not change its situation. And from his bidding the sun to keep its situation, it would be unjust to infer, that it moves round the earth at rest.

These, and similar expressions, are true and proper descriptions of the phenomena, as they appear to us; but as the scriptures were never intended to instruct us in philosophy and astronomy, they do not at all determine by what motions these phenomena are occasioned. And it has been justly observed, that part of the account recorded in the book of Joshua is merely a description of the appearance; Gibeon and Ajalon, and the whole land of Canaan lying in too northern a latitude for the sun or moon ever to be vertical to any part of it; and yet this was a just description of the phenomenon as it appeared to Joshua in the place where he then was; and if one part of the account merely describe the phenomena, the other must likewise be understood in the same manner.

Cicero, very pertinently to the same purpose, distinguishes "two sacred volumes, the one written, called the Bible; the other, Nature, or the World; God having manifested himself by two lights, the one of revelation, and the other of demonstration; accordingly, the interpreters of the former are divines, of the latter, mathematicians. As to matters of natural knowledge, the mathematicians are to be consulted; and as to the objects of faith, the prophets the former being no less interpreters, or apostles, from God to men, than the latter. And as the mathematicians would be judged to wander out of his province, if he should pretend to controversy, or fix aside any article of faith from principles of geometry; so it must be granted, that the divines are no less out of their limits, when they venture to pronounce on a point of natural knowledge, beyond the reach of any not verified in geometry and optics, merely from holy scriptures, which does not pretend to teach any thing of the matter."

For instances, we may quote Lactantius and Augustine; the first of whom rendered himself ridiculous by disputing from scripture, against the roundness of the earth; and the latter, against the antipodes. See *ANTIPODES*.

Having thus proved the motion of the earth, it is to be further observed, that the altitude of the pole being found at all times of the year, i. e. in all points of its annual orbit (the ecliptic) to be the same; it follows, that the earth proceeds in such manner along its orbit, as that its axis is constantly parallel to the axis of the world, and of consequence parallel to itself.

This motion, which Copernicus calls the motion of libration, may be well enough illustrated, by supposing a globe, with its axis parallel to that of the earth, painted on a flag, or ancient of a mat, moveable on its axis, and continually driven by the west wind, while it makes the tour of an island; it is evident, that in every situation of the ship, the axis of the painted globe will continue parallel to the axis of the world.

According to Sir Isaac Newton's principles, the earth's axis does, in every annual revolution, incline twice towards the ecliptic, and twice return to its former position: on which intuition it is, that the precession of the equinoctial points is supposed to depend.

EARTH, Latitude and Longitude of the. See *LATITUDE* and *LONGITUDE*.

EARTH, Inclination of the Axis of the. See *INCLINATION*, *AXIS*, and *ANGLE*.

EARTH, Quantity of matter, density and attractive power at its surface. See *DENSITY* and *PLANETS*.

EARTHEN pipes. See *FLOOR*.

EARTHINGS, in the general sense. See *INTERMENT*.

EARTHING, in Agriculture and Gardening, denotes the covering of vines, celery, and other herbs and plants with earth.

EARTHQUAKE, in Natural History, a vehement shake, or agitation of some considerable piece or part of the earth, from natural causes, attended with a terrible noise like thunder, and frequently with an eruption of water or fire, or effluvia of smoke or winds.

Earthquakes are the greatest and most formidable phenomena of nature. Aristotle and Pliny distinguish two kinds with respect to the manner of the shake, viz. a tremor and a pulse; the first being horizontal, in alternate vibrations, compared to the shaking of a person in an ague; the second perpendicular, up and down; which latter kind are also called by Aristotle, *spasmi*, from the resemblance of their motion to that of boiling.

EARTHQUAKES, Phenomena of. The Philosoph. Transact. furnish us with abundance of histories of earthquakes; particularly, one at Oxford in 1665; by Dr. Wallis and Mr. Boyle. Another at the same place in 1683, by Mr. Pigot. And another in Sicily in 1693-3, by Mr. Harrop, Fr. Alessandro Burgo, and Vin. Bonjurru, which last is one of the most terrible ones in all history.

This shook the whole island; and not only that, but Naples and Malta started in the shock. It was of the second kind mentioned by Aristotle and Pliny, viz. a perpendicular pulsation or concussion. It was impossible, said the noble Benjamins, for any body in this country to keep on their legs on the dancing earth; nay, those that lay on the ground were tossed from side to side on a rolling billow, and high walls leaped from their foundations several paces, &c. Phil. Trans. N° 207. The mischief it did is amazing; almost all the buildings in the countries were thrown down. Fifty-four cities and towns, beside an incredible number of villages, were either destroyed or greatly damaged. We shall only instance the fate of Catania, one of the most famous, ancient, and flourishing cities in the kingdom, the residence of several monarchs, and an university. This once famous, now unhappy Catania, to use the words of Fu. Burgos, had the greatest share in the tragedy. F. Antonio Serravalle being on his way thither, and at the distance of a few miles, observed a black cloud like night, hovering over the city; and there rose from the mouth of Montebello great spires of flame, which spread all around. The sea, all of a sudden, began to roar, and rise in billows; and there was a noise as if all the artillery in the world had been at once discharged. The birds flew about aloof; the cattle in the fields ran crying, &c. His and his companions horses stopped short, trembling; so that they were forced to alight. They were no sooner off, but they were lifted from the ground above two palms; when casting his eyes towards Catania, he with amazement saw nothing but a thick cloud of dust in the air. This was the scene of their calamity; for of the magnificent Catania, there was not the least vestige to be seen. S. Benjamins assures us, that of 18914 inhabitants, 18000 perished therein. The same author, from a computation of the inhabitants, before and after the earthquake, in the several cities and towns, finds that near 60000 perished out of 254900. Ibid. N° 202.

Jamais is remarkable for earthquakes. The inhabitants, Dr. Sloane informs us, expect one every year. This author gives us the history of one in 1687; and another horrible one in 1692, is described by several anonymous authors. In two minutes time this shook down and drowned nine-tenths of the town of Port-Royal. The houses sunk on-right, 30 or 40 fathoms deep. Phil. Trans. N° 209. The earth opening, swallowed up people; and they rose in other streets, some in the middle of the harbour; and yet many were saved, though there were 3000 people lost, and 1000 acres of land sunk. All the houses were thrown down throughout the island. One Hopkins had his plantation removed half a mile from its place. Of all wells, from one fathom to six or seven, the water flew out at the top with a vehement motion. While the houses on one side of the street were swallowed up, on the others they were thrown on heaps; and the sand in the street rose like waves in the sea, lifting up every body that stood on it, and immediately dropping down into pits; and at the same instant a flood of water breaking in, rolled them over and over; some catching hold of beams and rafters, &c. Ships and Boats in the harbour were over-set and lost; the Swan frigate, particularly, was thrown over by the motion of the sea and sinking of the wharf, and was driven over the tops of many houses. It was attended with a hollow rumbling noise like that of thunder. In less than a minute, three quarters of the houses, and the ground they stood on, with the inhabitants, were all sunk quite under water; and the little part left behind was no better than a heap of rubbish. The shake was so violent, that it threw people down on their knees or their faces as they were running about for shelter. The ground heaved and swelled like a rolling sea; and several houses, still standing, were thrust and moved some yards out of their places. A whole street is said to be twice as broad now as before; and in many places, the earth would crack, and open shut, quick and fall. Of which openings, two or three hundred might be seen at a time; in some whereof, the people were swallowed up; others, the earth closing, were caught by the middle, and pressed to death; as to others, the heads only appeared. The larger openings swallowed up houses; and out of some would issue whole rivers of waters, spouted up a great height into the air, and threatening a deluge to that part the earthquake swept. The whole was attended with clenches and offensive smells, the noise of falling mountains at a distance, &c. and the sky in a minute's time was turned dull and reddish like a glowing oven. Yet, as great a sufferer as Port Royal was, more houses were left standing therein than on the whole island beside. Scarce a planting-house or sugar-house was left standing in all Jamaica. A great part of them was swallowed up,

houses, people, trees, and all at once; in lieu of which, afterwards, appeared great pools of water, which, when dried up, left nothing but sand, without any mark that ever tree or plant had been thereon. Above 12 miles from the sea, the earth gaped, and spouted out with a prodigious force vast quantities of water into the air; yet the greatest violence was among the mountains and rocks; and it is a general opinion, that the nearer the mountains the greater was the shake; and that the cause thereof lay there. Most of the rivers were stopped up for 24 hours, by the falling of the mountains, till swelling up, they made themselves new tracks and channels, tearing up in their passage trees, &c. After the great shake, many of those people who escaped got on board ships in the harbour, where many continued above two months; the shakes all that time being so violent, and coming so thick, sometimes two or three in an hour, accompanied with frightful noises like a rushing wind, or a hollow rumbling thunder, with brimstone-blasts, that they durst not come ashore. The consequence of the earthquake was a general famine, from the uniform vapours belched forth, which swept away above 3000 persons of those who were left. Ibid. After the detail of these horrible convulsions, the reader will have but little curiosity left for the phenomena of the earthquake at Lima in 1687, described by Fr. Alvarez de Toledo, wherein above 5000 persons were destroyed; this being of the vibratory kind, so that the bells in the church rung of themselves; or that at Batavia, in 1690, by Wiram; that in the north of England, in 1703, by Mr. Thoeby; that in New-England in 1693 and 1694, by Dr. Mather; that of Italy in 1742; that of Lima and the port of Callao in Peru, in 1746, which lasted fifteen minutes, and destroyed most of the buildings in the city, destroyed most of the inhabitants, and swallowed up several ships therein the port; that of London in 1749; those in 1750, felt in many parts of England; that of 1779, felt in the north of England; or lastly, that of Lisbon in 1755; though this deserves a more particular account than many others of much less considerable extent and duration. The three preceding years had been remarkably dry, inasmuch, that some springs which had been plentifully supplied with water were totally lost; and the predominant winds were east and north-east, accompanied with various, though very small motions and tremblings of the earth. The spring of the year 1755 was very rainy and wet; the weather on the day preceding the earthquake, which happened on the 31st of November, was clear, and uncommonly warm for the season, and had continued clear and rather warmer than usual for several days before. The day of the earthquake broke with a serene sky, the wind continuing at east; but about 9 o'clock the sun began to grow dim; and soon after was heard a rumbling noise, like that of carriages, which increased to such a degree as to equal that of the loudest cannon; upon which the first shock was felt, which was immediately succeeded by a second and third, the whole duration of which was about 8 minutes; about 12 o'clock another shock was felt. During the first shock, the greatest part of the public edifices and other buildings of the city were thrown down; and not less than 60,000 of its inhabitants buried in the ruins. The earth opened in fissures in several parts, and several light flames of fire were observed to issue from the sides of the mountains resembling those of kindled charcoal. Subterraneous rumblings were also felt, attended with a discharge of great quantities of smoke. The water in the sea rose several times, and in a few minutes made three fluxes and re-fluxes, rising above the greatest spring-tides no less than 1; English feet. The shock was so violent 50 leagues off at sea, as greatly to injure the deck of a ship, and to lead the captain to apprehend, that he had mistaken his reckoning, and struck on a rock. The shock was also felt about the same time at Oporto, by which the whole city was shaken, several chimnies, stones, and crosses, were thrown down, and some buildings opened at top; and the swelling in the river was so considerable, that two large ships, which were just got over the bar, were driven back into the harbour. The same shock was equally violent at Madrid, Seville, and Cadix; and in this last place the sea rose in a wave at least 60 feet higher than usual, dashed against the rocks on the west part of the town, and against the walls with such violence as to beat in the breast-work and a great part of the walls, so that several persons were drowned by it. The day when the earthquake happened at Cadix was as clear and serene as the finest summer-day in England. Many other cities, both in Spain and Portugal, were considerably damaged. The effects of this earthquake, in violently agitating the waters, were perceived in many parts of England, Scotland, and Ireland; and the shock not only reached to Switzerland, Holland, and other parts

parts of Europe, but it was communicated to Africa, and destroyed several cities on the coast of Barbary; and it was also felt about the same time to the island of Madeira, where the water rose full 15 feet perpendicular above high-water mark. See Phil. Trans. N° 462, 463, 497; or vol. xli. p. 601, &c. vol. xlix. art. lvi. p. 261—244.

M. Lomonow presented a paper to the Royal Academy of Sciences at Paris in 1753, in which he endeavours to shew that the formation of metals is a necessary consequence of earthquakes. He supposes that the fire, occasioned by the fulphureous matter with which the interior parts of the earth abound, acts on the fossil substances and the vegetable salts contained in them, and deposited in the cavities of the earth, and reduces the whole into a mineral state; and that the minerals dissolved by the fire are distributed into beds and veins, as they are found to exist in the mine.

We will now relieve the reader after this long account, with some attempts towards a theory of earthquakes.

Earthquakes, Causes of. Naturalists are here divided. Some ascribe earthquakes to water, others to fire, and others to air; and all of them with some reason. To conceive which, it is to be observed, that the earth every where abounds with huge subterraneous caverns, veins, and canals, particularly about the roots of mountains; that of these cavities, veins, &c. some are full of water, whence are composed gulls, abysses, springs, rivulets; and others full of exhalations; and that some parts of the earth are replete with nitre, sulphur, bitumen, vitriol, &c.

This premised, 1. The earth itself may be the cause of its own shaking; when the roots or basis of some large mass being dissolved, or worn away by a fluid underneath, it sinks into the fame; and, with its weight, occasions a tremor of the adjacent parts, and produces a noise, and frequently an inundation of water.

2. The subterraneous waters may occasion earthquakes, by their overflowing, cutting out new courses, &c. Add, that the water, being heated, and rarefied by the subterraneous fire, may emit fumes, blads, &c. which, by their action, either on the water, or immediately on the earth itself, may occasion great succussions.

3. The air may be the cause of earthquakes, for air being a collection of fumes and vapours raised from the earth and waters, if it be pent up in the too narrow viscera of the earth, the subterraneous, or its own native heat, rarefying and expanding it, the force wherewith it endeavours to escape may shake the earth: hence there will arise a diverse species of earthquakes, according to the different position, quantity, &c. of the imprisoned air.

Lastly, Fire is a principal cause of earthquakes; both as it produces the aforesaid subterraneous aura or vapour; and as this aura or spirit, from the different matter and composition wherof arise sulphur, bitumen, and other inflammable matters, is kindled either from some other fire it meets with, or from its collision against hard bodies, or its intermixture with other fluids, by which means bursting out into a greater compass, the place becomes too narrow for it: so that pressing against it on all sides, the adjoining parts are shaken; till, having made itself a passage, it spends itself in a volcano, or burning mountain.

But to come nearer to the point, Dr. Lister, in Philosoph. Transact. N° 157, is of opinion, that the material cause of thunder, lightning, and earthquakes, is one, and the same, viz. the inflammable breath of the pyrites, which is a sublimated sulphur, and will take fire of itself. For the true theory of lightning, &c. see LIGHTNING.

The difference between these three terrible phenomena, he takes only to consist in this: that this sulphur in the former is fired in the air; and in the latter, under-ground; which is a notion that Pliny had long before him: *quid enim, says he, aliud est in terra tremor, quam in nubis tonitruus?*

This he thinks abundantly indicated by the same fulphureous smell being found in any thing burnt with lightning, and in the waters, &c. cast up in earthquakes, and even in the air before and after them.

Add that they agree in the manner of the noise; which is carried on as in a train, fired, the one rolling and rattling through the air, takes fire as the vapours chance to drive; as the other fired under-ground, in like manner, moves with a defolatory noise.

Thunder, which is the effect of the trembling of the air, caused by the same vapours dispersed through it, has force enough to shake our houses; and it is by no means improbable that there may be thunder and lightning under-ground, in some vault repositories there; especially if we reflect, that the matter which composes the noisy vapour above us is contained in much larger quantities under-ground. Philosophical Transactions, N° 202.

VOL. II. N° 107.

That the earth abounds in cavities, every body allows; and that these subterraneous cavities are, at certain times, and in certain seasons, full of inflammable vapours, the damps in our mines sufficiently witness; which, fired, do every thing as in an earthquake, only in a lesser degree.

That the pyrites alone, of all the known minerals, yields this inflammable vapour, is highly probable; because no mineral or ore whatsoever is sulphureous, but as it is wholly or in part a pyrites; and there is but one species of brimstone, at least with us in England, which the pyrites naturally and only yields. The sulphur vivum or natural brimstone, which is found in and about the burning mountains, is certainly the effect of sublimation; and those great quantities of it said to be found about the skirts of volcanoes, are only an argument of the long duration and vehemence of those fires. Possibly, the pyrites of the volcanoes, or burning mountains, may be more sulphureous than ours; and indeed it is plain, that some of ours in England are very lean, and hold but little sulphur; others again very much, which may be one reason why England is so little troubled with earthquakes; and Italy, and almost round the Mediterranean sea, so very much; though another reason is, the paucity of pyrites in England, compared with those places. Comparing our earthquakes, thunder and lightning, with theirs, it is observed, that there it lightens almost daily, especially in summer-time, here seldom; there thunder and lightning are of long duration, here they are soon over; there the earthquakes are frequent, long, and terrible, with many paroxysms in a day, and thus renewed for many days; here they are very short, only of a few minutes, and scarce perceptible. To this purpose, the subterraneous cavities in England are small and few, compared with the vast vaults in those parts of the world, which is evident, from the sudden disappearance of whole mountains and islands.

Dr. Woodward gives us another theory of earthquakes. He endeavours to shew, that the subterraneous heat or fire (which is continually elevating water out of the abyss to furnish the earth with rain, dew, springs, and rivers) being stopped in any part of the earth, and so diverted from its ordinary course by some accidental glut or obstruction in the pores or passages through which it used to ascend to the surface, becomes, by such means, preternaturally assembled in a greater quantity than usual, into one place, and therefore causeth a great rarefaction and intumescence of the water of the abyss, putting it into great commotions and disorders, and at the same time making the like effort on the earth, which, being expanded upon the face of the abyss, occasions the agitation and concussion which we call an earthquake.

This effort, in some earthquakes, he observes, is so vehement that it splits and tears the earth, making cracks and chasms in it some miles in length, which open at the instant of the shocks, and close again at the intervals betwixt them; nay, it is sometimes so violent, that it forces the super-incumbent strata, breaks them all throughout, and thereby perfectly undermines and ruins the foundation of them; so that these falling, the whole tract, as far as the shock is over, sinks down into the abyss, and is swallowed up by it; the water thereof immediately rising up, and forming a lake in the place where the said tract before was. That this effort being made in all directions indifferently, the fire dilating and expanding on all hands, and endeavouring to get room, and making its way through all obstacles, acts as violently on the water of the abyss beneath as on the earth above, forcing it forth which way soever it can find vent or passage, as well through its ordinary exits, wells, springs, and the outlets of rivers, as through the chasms then newly opened, through the canini or spiracles of JETNA, or other neighbouring volcanoes; and those hiatuses at the bottom of the sea, whereby the abyss below opens into it, and communicates with it. That as the water resident in the abyss is, in all parts of it, flooded with a considerable quantity of heat, and more especially in those where these extraordinary aggregations of this fire happen; so likewise is the water, which is thus forced out of it, inasmuch that, when thrown forth and mixed with the waters of wells, or springs of rivers, and the sea, it renders them very sensibly hot.

He adds, that though the abyss be liable to these commotions in all parts, yet the effects are no where very remarkable, except in those countries which are mountainous, and consequently stony and cavernous underneath; and especially where, the disposition of the strata is such that those caverns open into the abyss, and so freely admit and entertain the fire, which assembling therein is the cause of the shock; it naturally seeking its course that way, where it finds the readiest reception, which is towards those caverns. Besides that those parts

of the earth which abound with strata of stone, or marble, making the strongest opposition to this effort, are the most furiously shattered, and suffer much more by it than those which consist of gravel, sand, and the like laxer matter, which more easily give way, and make not so great resistance; but, above all, those countries which yield great stores of sulphur and nitre, are by far the most injured and incommode by earthquakes; those minerals constituting in the earth a kind of natural gunpowder, which taking fire upon this emblemage and approach of it, occasions that murmuring noise or subterranean thunder which is heard rumbling in the bowels of the earth during earthquakes; and, by the assistance of its explosive power, renders the shock much greater, so as sometimes to make miserable havoc and destruction. And it is for this reason that Italy, Sicily, Anatolia and some parts of Greece, have been so long and so often alarmed and harried by earthquakes; these countries being all mountainous and cavernous, abounding with stone and marble, and abounding sulphur and nitre in great plenty.

It is observed that *Ætna*, *Vesuvius*, *Hæcla*, and the other volcanoes, are only so many spiracles serving for the discharge of this subterranean fire, when it is thus preternaturally assembled; that where there happens to be such a structure and conformation of the interior parts of the earth, as that the fire may pass freely and without impediment from the caverns whither it ascends unto those spiracles, it then readily and easily gets out, from time to time, without shaking or disturbing the earth; but where such communication is wanting, or the passage is not sufficiently large and open, so that it cannot come at the spiracles, it heaves up and shakes the earth with greater or less impetuosity, according to the quantity of fire thus assembled, till it has made its way to the mouth of the volcano: that therefore there are source any countries much annoyed with earthquakes, which have not one of these fiery vents, constantly in flames when any earthquake happens, as discharging that fire, which, whilst underneath, was the cause of the disalter: lastly, that were it not for these diversicula, it would rage in the bowels of the earth much more furiously, and make greater havoc than it doth.

Having thus shewn how fire and water contribute to the phenomena of earthquakes; let us next consider the effects of air.

M. Amontons, in the *Memoirs de l'Acad. des Sciences*, no. 1703, has an express discourse to prove, that on the foundation of the new experiments of the weight and spring of the air, a moderate degree of heat may bring the air into a condition capable of causing earthquakes. See *Air, Elasticity of*.

The ingenious Mr. Michell has published an elaborate paper of conjectures concerning the cause, and of observations on the phenomena of earthquakes. He supposes that they are occasioned by subterraneous fires; which, if a large quantity of water should be let out upon them suddenly, may produce a vapour, whose quantity and elastic force may be fully sufficient for this purpose. The facts by which he supports this hypothesis are the following: 1. The same places are subject to returns of earthquakes, not only at small intervals for some time after any considerable one has happened, but also at greater intervals of some ages; and these, he apprehends, are very consistent with the cause assigned. Since subterraneous fires, as well as volcanoes, which they nearly resemble, may be reasonably supposed, and are found in fact to subsist for many ages; and may produce their effect, like the raging of volcanoes, at unequal intervals, and with unequal degrees of force. 2. Those places that are in the neighbourhood of burning mountains are always subject to frequent earthquakes, and the eruptions of those mountains, when violent, are generally attended with them; and this is a consideration, he says, which affords a strong argument of their proceeding from a cause of the same kind; more especially, as the earth is composed of several regular strata, which are very extensive, and lie more inclining from the mountainous countries, than the countries themselves. Hence he infers, that those strata of combustible materials which break out in volcanoes on the tops of hills, are to be found at a considerable depth under-ground in the level and low countries near them; and if the same strata should be on fire in any places under such countries as well as the tops of hills, all vapours of whatever kind, raised from these fires, must be pent up, unless so far as they can open for themselves a passage between the strata; whereas the vapours raised from volcanoes find a vent, and are discharged in blasts from the mouths of them; and yet when they find a vent, they are capable of shaking the country to the distance of ten or twenty miles round; what then may we not expect

from them when they are confined? Thus Mr. Michell accounts for the fact, that the most extensive earthquakes take their rise from the level and low countries; and more especially from the seas, which are waters covering such countries. 3. The motion of the earth in earthquakes is partly tremulous, and partly propagated by waves, which succeed one another sometimes at larger and sometimes at smaller distances; and this latter motion is generally propagated much farther than the former. Both these phenomena, it is observed, may be accounted for by the supposition, that earthquakes are caused by vapours raised from waters suddenly let out on subterraneous fires. As a small quantity of vapour almost instantly generated at some considerable depth below the surface of the earth; so a very large quantity (whether generated instantly, or in any small portion of time) will produce a wave-like motion. A large quantity of vapour may be conceived to raise the earth in a wave as it passes between the strata, which it may easily separate in an horizontal direction, there being, as it is supposed, little or no cohesion between one stratum and another. Thus, if a large quantity of vapour should continue to be generated for some time, several waves might be produced by it. The vibratory motion, occasioned by the first impulse of the vapour, being propagated through the solid parts of the earth, will much sooner become too weak to be perceived than the wave-like motion, occasioned by the vapour insinuating itself between the strata, and capable of being propagated to very great distances. 4. Earthquakes generally come to one and the same place from the same point of the compass; and their velocity is much the same; whereas the velocity of earthquakes of different countries is very different; i. e. earthquakes derived from the same subterraneous fire must come to the same place in the same direction; and those only which are derived from different fires will come from different points of the compass. 5. The great Lisbon earthquake has been succeeded by several local ones since, the extent of which has been much less: the vapour produced by one subterraneous fire distributing the materials over some other fire. For a more particular account of Mr. Michell's theory, and of the various facts which he alleges in illustration and support of it, we must refer to *Phil. Trans.* vol. ii. art. 35. p. 566-634.

EARTHQUAKES, the theory of, hath received considerable alteration and improvement from modern electrical discoveries. The first person who advanced the notion, that earthquakes were probably caused by electricity, was Dr. Stukeley, on occasion of those that happened in England in the years 1749 and 1750. He urges a variety of objections against the common hypothesis, which ascribes earthquakes to subterraneous winds, fires, vapours, or any thing that occasions an explosion, and thus heaves up the ground. He thinks there is no evidence of the cavernous structure of the earth, which this hypothesis requires; but that on the contrary, there is reason to believe that it is in a great measure solid. Earthquakes have also frequently happened without any eruption of fire, vapour, smoke, or smell, which he thinks is utterly inconsistent with the supposition of their being occasioned by any subterraneous vapours; especially in cases where the shock is of considerable extent; besides, this is a cause altogether inadequate to such an effect: for a subterraneous power, capable of moving a surface of earth only thirty miles in diameter, must be lodged at least fifteen or twenty miles below the surface, and move an inverted cone of solid earth, whose base is thirty miles in diameter, and axis fifteen or twenty miles, which he judges to be absolutely impossible; how much more inconceivable, then, that any such power could produce the earthquake of 1755, which was felt in various parts of Europe and Africa, and the Atlantic Ocean; or that of Asia Minor, A. D. 17, by which thirteen great cities were destroyed in one night, and which shook a mass of earth three hundred miles in diameter, in order to which the moving power, if it had been internal fire, or vapour, must have been lodged two hundred miles below the surface! Farther, in earthquakes the effect is instantaneous; whereas the operation of elastic vapour, and the discharge of it, must be gradual, and require a long space of time: and if they were owing to explosions, they must alter the surface of the country where they happened, destroy the fountains and springs, and change the course of its rivers, which is contradicted by history and observation. To all which it is added, that the strokes which tribes receive during an earthquake must be occasioned by something that could communicate motion with a much greater velocity than any heaving of the earth under the sea by the elasticity of generated vapours, which would only produce a gradual swell, and not an impulse of the water, resembling a thump against the bottom of a ship, or striking against a rock. Dr.

Stukeley.

Stukeley, finding the common hypothesis insufficient, was led to conclude that earthquakes were proper electrical shocks; and a particular survey of the phenomena that either, precede or attend them, confirmed this opinion: he observed, that the weather was usually dry and warm for some time before an earthquake happened, and that the surface of the ground is thus previously disposed for that kind of electrical vibration in which it consists; whilst at the same time, in some places where earthquakes have happened, the internal parts, at a small depth below the surface, are moist and boggy; and thence he infers, that they reach very little below the surface. He adds, that the southern regions are more subject to earthquakes than the northern, on account of the greater warmth and dryness of the earth and air, which are qualities so necessary to electricity. It was also observed, that before the earthquake at London in 1749, all vegetables were remarkably forward, and electricity is well known to quicken vegetation. They were likewise preceded by frequent and singular appearances of the *aurore borealis*, and *austriality*, and by a variety of other meteors which indicate an electrical state of the atmosphere. Dr. Stukeley apprehends, that, in this state of the earth and air, nothing more is necessary to produce an earthquake than the approach of a non-electric cloud to any part of the earth, when in an highly electrified state, and the discharge of its contents upon it; and that as the discharge from an excited tube occasions a commotion in the human body, so the shock, produced by the discharge between the cloud and many miles in compass of solid earth, must be an earthquake, and the snap from the contact be the noise attending it. He supposes that a large black cloud which suddenly covered the hemisphere a little before the earthquake of 1749, might have occasioned the shock, by the discharge of a shower. The noise, it has been observed, usually precedes the shock; whereas, if the concussion depended upon a subterranean eruption, it must have been quite the contrary. The flames and sulphureous smells, which sometimes attend earthquakes, are more easily accounted for, as Dr. Stukeley thinks, from the supposition of their being electrical phenomena than on any other hypothesis. The sudden, extensive agitation, both of land and water, occasioned by earthquakes, can only be effected by electricity. The little damage generally done by earthquakes, and the nature of the impulse which they give to ships, already taken notice of, suggest an argument, that they are owing not to any convulsion in the bowels of the earth, but to a uniform vibration along its surface, occasioned by an electrical snap; and that they are electrical phenomena. Dr. Stukeley farther infers, from their chiefly affecting the sea-coast, places near rivers, we may add also eminences; and finally from the effects which they produce on weak constitutions, such as pains in the back, head-aches, colics, &c. similar to those occasioned sometimes by electrification. After all, he does not presume to say, how the earth and atmosphere are put into that electrical and vibratory state, which prepares them to give or receive that snap and shock, which is called an earthquake; but this he thinks as difficult to account for as magnetism, gravitation, molecular motion, and many other secrets in nature. Several circumstances have been remarked by other writers, which confirm the theory that supposes earthquakes to be electrical phenomena. Signior Beccaria, whose name often occurs in the history of electricity, agrees with Dr. Stukeley, in supposing, that earthquakes are electrical phenomena; but he imagines, that the electric matter which occasions them is lodged deep in the bowels of the earth; and if in this situation its equilibrium should by any means be destroyed, so that the best method of restoring it shall be by the fluid's bursting its way into the air, and traversing several miles of the atmosphere to come to the place where it is wanted; it may easily be conceived, that violent concussions may be given to the earth, by the sudden passages of this powerful agent; and that the electric fluid is sometimes collected in the bowels of the earth, he thinks probable from the appearance of *ignei fatui* in mines, which sometimes happens, and is very probably an electrical phenomenon. This ingenious philosopher observes that if two pieces of glass, enclosing a thin piece of metal, be held in the hand, while a large shock is sent through them, a strong concussion or vibration will be felt, which sometimes breaks them to pieces. Mr. Henry, another excellent electrician, has discovered a method of increasing the effect of the explosion upon glass, so as to afford a very natural idea of an earthquake. Between the ends of two wires, laid on a piece of glass, with their extremities pointing to each other, and about an inch distant, through which the discharge is to be made, he places a thick piece of ivory upon the glass, and on the ivory a weight at pleasure, from one fourth of an ounce to six pounds; the glass

is broken by an explosion into innumerable fragments, and some of it is reduced into an impalpable powder; the weight is shook by the explosion, and sometimes thrown off from the ivory. In this experiment if the glass is very thick, so that the force of the explosion is not sufficient to break it, it will be found marked with the most lively prismatic colours. The appearance of an earthquake may be also represented by causing an explosion of a battery to pass over the surface of any substances on which small sticks or cards are placed, which will never fail to be shook, and often be thrown down by the explosion; or, by making a discharge over the surface of water, in which case the report will be much louder than when the discharge is made through the air, and a hand plunged deep into the water will feel the concussion; and we may add, that the spark which passes over the surface of the water in this experiment, bears a great resemblance to those balls of fire that have sometimes been seen over the surface of the sea or land in the time of an earthquake. Dr. Priestley contrived various methods of exhibiting the phenomena of earthquakes. He made the electric flash to pass over wet boards swimming in water, over either of these separately, or over both at once, on which pillars, &c. were erected; and thus, whilst the board represented the earth, and the water the sea, the phenomena of both during an earthquake were exhibited at the same time. Dr. Priestley, the ingenious historian of electricity, after having largely recited the observations of Dr. Stukeley and Signior Beccaria on the subject of earthquakes, of which we have given a summary in the foregoing part of this article, does not absolutely decide which of these two philosophers has advanced the more probable opinion concerning the seat of the electric matter which occasions earthquakes; but he thinks a more probable general hypothesis than either of them may be formed out of them both. Suppose, says he, the electric matter to be some way or other accumulated on one part of the surface of the earth, and on account of the dryness of the season, not easily to diffuse itself; it may, as Signior Beccaria supposes, force itself a way into the higher regions of the air, forming clouds in its passage out of the vapours which float in the atmosphere, and occasion a sudden shower, which may farther promote the passage of the fluid. The whole surface thus unloaded, will receive a concussion, like any other conducting substance, on passing with, or receiving, a quantity of the electric fluid. The rushing noise will likewise sweep over the whole extent of the country. And, upon this supposition also, the fluid, in its discharge from the country, will naturally follow the course of the rivers, and also take the advantage of any eminences to facilitate its ascent into the higher regions of the air. See farther on this subject, Phil. Trans. vol. xli. p. 644, &c. Beccaria Lettre dell' Elettricità, p. 216. 262. &c. or Priestley's Hist. of Electricity, Period 2. fed 12.

EARTHQUAKES, Artificial. Chemistry furnishes us with a method of making artificial earthquakes, which shall have all the great effects of natural ones; which, as it may illustrate the process of nature in the production of these terrible phenomena under-ground, we shall here add.

To twenty pounds of iron filings, add as many of sulphur; mix, work, and temper the whole together with a little water, so as to form a mass of the consistence of a firm paste. This being buried three or four feet underground, in six or seven hours time, will have a prodigious effect; the earth will begin to tremble, crack, and smoke, and fire and flame will burst through.

Such is the effect even of two cold bodies, in cold ground; and there only wants a sufficient quantity of this mixture to produce a true *Ætna*. If it were supposed to burst out under the sea, it would produce a water-spout; and if it were in the clouds, the effect would be thunder and lightning. However, *water-spouts* and *thunder* are, without doubt, electrical phenomena.

EARTHWORM, *Lumbricus*, in Zoology. A well-known insect, belonging to the order of *Insecta*, containing the parts of generation of both sexes in each individual; long, destitute of feet, and of a reddish colour; of an oblong form, considerably thick, rounded in shape, and covered with a soft and slender skin, marked with annular ridges and furrows. When full grown, it is often ten inches or more in length, and more than a third of an inch in diameter. Its colour is a dusky red.

It is common every where, at little depths, under the surface of the earth; it is not unfrequently also met with in the human intestines, as well as in those of other animals, in which state it has been supposed a different creature, and called by a new name.

Besides the common earthworm, there is found another species of *lumbricus* in the mud about the sea shores, very large, growing very often to a foot or more in length; it entirely resembles the other, only that it is of a paler red, and has its skin covered with little pro-

minences,

minences, which make it rough and scabrous to the touch.

Eurhœmia are by some esteemed of great virtue in medicine, and are said to be diuretic, diaphoretic, and anodyne; as also difficult, emollient, and openers of obstructions; and are prescribed in apoplexies, spasms, and all nervous affections, and in the jaundice, dropsies, and colics.

EASE, in the *Spa-language*, signifies as much as slacken, or let go slack.

Thus they say, *ease* the bowline, *ease* the sheet; that is, let them go slack.

EASE the *ship*, in *Sea-language*, is the command given by the pilot to the steersman, to put the helm close to the lee-side; or *hard-a-lee*, when the ship is expected to pitch or plunge her fore-part deep in the water while close hauled.

EASE, *Chapel of*. See **CHAPEL**.

EASEL-PIECES, among *Painters*, such smaller pieces, either portraits or landscapes, which are painted on the *easel*, i. e. the frame whereon the canvass is laid.

They are thus called to distinguish them from larger pictures drawn on walls, ceilings, &c.

EASEMENT, in *Law*, a service or convenience which one neighbour has of another by charter or prescription, without profit; as a way through his ground, a link, or the like.

In the civil law, *ejusdem* are called, *servitus prædii*.

EAST, in *Cosmography*, one of the cardinal points of the horizon; being the point wherein the prime vertical intersects that quarter of the horizon in which the sun rises when in the equinoctial.

The word *east* is Saxon. In Italy, and throughout the Mediterranean, the *east*-wind is called the *levante*. In Greek, *anatolē* and *anatolus*, because it comes from the side of the sun, *ανατολη*. In Latin, *orient*.

To find the *east* and west line points, &c. see **MERIDIAN-LINE**.

EAST-WIND, is that which blows from the *east* point. See **WIND**.

EAST-DIAL. See **DIAL**.

EAST-INDIA COMPANIES. See **COMPANY**.

EAST-INDIA SILE. See **SILE**.

EAST, Moving for. See **MOORING**.

EASTERN. See **ORIENTAL**.

EASTER, a feast of the church, held in memory of our Saviour's resurrection.

The Greeks and Latins call it *pascha*, *pascha*, originally a Hebrew word, signifying *passage*, applied to the feast of the Passover which is held among the Jews much about the same time. In English it is called *Easter*, from *Egghen*, a goddess worshipped with peculiar ceremony in the month of April.

The observance of this festival is as ancient as the time of the apostles; for it is certain that the Christians of the second century celebrated anniversary festivals in commemoration of the death and resurrection of Christ, and of the edition of the Holy Ghost upon the apostles. The day which was observed as the anniversary of Christ's death was called the *paschal* day, because it was considered as the same with that on which the Jews celebrated their Passover. But towards the close of this century, a dispute commenced about the particular time in which this feast was to be kept. The Asiatic churches kept it on the 14th day of the first Jewish month, and three days after commemorated the resurrection of the Redeemer, pleading on behalf of this practice the authority of the apostles, Philip and John, and the example of Christ, who held his paschal feast on the same day that the Jews celebrated their passover. The western churches celebrated their paschal feast on the night that preceded the anniversary of Christ's resurrection, and thus connected the commemoration of his death, and of his resurrection; and they pleaded the authority of the apostles Peter and Paul. One principal inconvenience attending the Asiatic method was, that this great festival was commonly held on other days of the week than the *first*. Victor, bishop of Rome, toward the close of the second century, attempted to force the Asiatic churches, by the pretended authority of his laws and decrees, to follow the rule which was observed by the western churches; they refused to submit, and were excommunicated by Victor. However, in consequence of the mild interposition of Irenæus, bishop of Lyons, the disputants retained their own customs till the fourth century, when the council of Nice abolished that of the Asiatics, and rendered the time of the celebration of *Easter* the same through all the Christian churches.

Easter is one of the most considerable festivals in the Christian calendar; being that which regulates and determines the times of all the other moveable feasts.

The rule for the celebration of *Easter*, fixed by the coun-

cil of Nice, in the year 325, is that it be held on the Sunday which falls upon, or next after, the full moon next after the 21st of March; i. e. the Sunday which falls upon, or next after the first full moon after the vernal equinox.

The reason of which decree was, that the Christians might avoid celebrating their *Easter* at the same time with the Jewish passover, which, according to the institution of Moses, was held the very day of the full moon.

To find *Easter* agreeable to this rule, the method that obtained throughout the church, from the time of Dionysius Exiguus to that of the reformation of the calendar under pope Gregory; and which still obtains in countries where the Gregorian correction is not admitted, is, by means of the golden numbers, duly distributed throughout the Julian calendar.

The vernal equinox, at the time of the Nicene council, happening on the 21st of March, has been, upon Dionysius's authority, affixed to the same day of the Julian year ever since; so that in the Julian way of computing, no full moon is paschal, but that immediately after the 21st of March: therefore, *Easter* can never happen earlier than the 22d of March. Now, by finding the full moons next after the 21st of March, for the several golden numbers or years of the lunar cycle, we shall have a table for finding *Easter* for ever.

Such table being of considerable use in the Julian computation, we shall here subjoin it.

Gold. Numb.	Full Moons next after Ver. Equin.	Gold. Numb.	Full Moons next after Ver. Equin.
I	5 April, D	XI	15 April, G
II	25 March, C	XII	4 April, C
III	13 April, E	XIII	24 March, F
IV	2 April, A	XIV	12 April, D
V	22 March, D	XV	1 April, G
VI	10 April, B	XVI	21 March, C
VII	30 March, E	XVII	9 April, A
VIII	18 April, C	XVIII	29 March, D
IX	7 April, F	XIX	17 April, B
X	27 March, B		

Now to find *Easter* for any given year, find the dominical letter, and the golden number of the given year, as directed under **DOMINICAL LETTER** and **GOLDEN NUMBERS**.

Then in the table, seeking the dominical letter, with the day of the paschal full moon, and the Sunday letter annexed thereto; compare this letter with the dominical letter of the given year, that it may appear how many days are to be added to the day of the paschal full moon to give *Easter*-day.

E. gr. In the year 1715, the dominical letter is B, and the golden number VI; consequently the paschal full moon is fixed, by the table, to the 10th of April; whose Sunday letter being B, the dominical letter given, itself, is a Sunday; and therefore *Easter* will fall on the eighth day following, viz. on the 17th of April.

But in this computation, the vernal equinox is supposed affixed to the 21st of March; and the cycle of nineteen years, or golden numbers, is supposed to point out the places of the new and full moons exactly; both which suppositions are erroneous. Whence it follows, that the Julian *Easter* never happens at its due time, unless by accident.

For an instance of the error, it may be observed, that in the year 1715, the vernal equinox falls on the 10th of March, eleven days before the rule supposes it; and the paschal full moon on the 7th of April, three days earlier than was supposed. *Easter*-day, therefore, which is held on the 17th of April, should be held on the 10th.

This error was grown to such a pitch, in course of time, that pope Gregory XIII. thought it necessary to correct it; and accordingly, in the year 1582, by the advice of Aloysius Lilius, he ordered ten days to be thrown out of October, so to bring back the vernal equinox to its old place, viz. the 21st of March; and hence the Gregorian calendar, Gregorian year, &c.

This correction, however, did not entirely remove the error; for the equinoxes and solstices still anticipate 1 h. 53' 20" in every 400 Gregorian years; but the difference is so inconsiderable as not to amount to 24 hours, or to one whole day in less than 5082 Gregorian years. See **DIFFERENCE**.

To find *Easter* by the **GOLDEN NUMBERS**, see **NUMBER OF DAYS**.

In the new or Gregorian computation, in lieu of golden numbers, the time of *Easter* is found by means of epacts contrived for that purpose. See **EPACT**.

Having the dominical letter and the epact, *Easter*-day

may be found by the two following rules: 1. For finding *Easter* limit, or the day of the paschal full moon from March the first inclusive; add 6 to the epoch, and if this sum exceeds 30, 30 must be taken from it; the remainder subtracted from 30 will give the limit, which is never to exceed 40, nor fall short of 21. 2. From the limit and dominical letter, *Easter-day* may be found, by adding 4 to the number of the dominical letter, subtracting the sum from the limit, and the remainder from the next higher number, which is exactly divisible by 7; add the last remainder to the limit, and the sum will give the number of days from the first of March to *Easter-day*, both inclusive. Thus for the year 1778, the epoch is 1, and the dominical letter D: $6+1=7$; $30-7=23$ paschal limit; $43-8$, the sum of 4 and the dominical letter, = 35; and $43-35=8$, which added to 23, the limit gives 30, or the number of days from March the 1st inclusive to *Easter-day*, or 19th of April.

The following table renders the finding of *Easter* in the Gregorian year from the year 1700 to the year 1900 very easy.

Epochs.	Paschal full Moons.	Epochs.	Paschal full Moons.
X	12 April, E	IX	4 April, C
XI	2 April, A	XX	14 March, F
XXII	21 March, D	I	12 April, D
III	10 April, B	XII	1 April, G
XIV	30 March, E	XXIII	21 March, C
XXV	18 April, C	IV	9 April, A
VI	7 April, F	XV	29 March, D
XVII	27 March, B	XXVI	17 April, B
XVIII	15 April, G	VII	6 April, E
		XVIII	16 March, A

Now, to find *Easter* for any given Gregorian year, seek the dominical letter and the Gregorian epoch, as shown under EPOCH, &c. Find the epoch in the table, and note the paschal full moon, with the weekly letter corresponding to the same. The rest is performed, as already taught for the Julian *Easter*.

E. p. the dominical letter of 1778 is D; and the epoch 1, consequently the paschal full moon falls on the 12th of April D, which is therefore Sunday, and *Easter-day* is the 19th of April, as before.

Though the Gregorian calendar be doubtless preferable to the Julian, yet it also has its defects. It cannot, for instance, keep the equinox fixed on the 21st of March, but it will sometimes fall on the 19th, and sometimes on the 23d.

Add, that the full moon happening on the 20th of March, might sometimes be paschal; yet it is not allowed as such in the Gregorian computation; as on the contrary, the full moon of the 22d of March may be allowed for paschal, which it is not. Scalliger and Calvisius have also proved other inaccuracies in this calendar. See CALENDAR. See an excellent paper on this subject by the earl of Macleod, in the Phil. Trans. vol. xi. p. 417. See EPOCH and GOLDEN NUMBER.

EASTER TERM. See TERM.

EASTERLING MONEY. See STERLING.

EASTERN AMPHITUDE, Church, Arabian, Ocean. See the substantives.

EATUAS, in *Modern History*, a name which the inhabitants of Otaheite in the South Sea give to an imaginary inferior race of deities; two of whom, they say, at some remote period of time, inhabited the earth, and were the parents of the first man. The term is derived from *etia*, which signifies *father*. These subordinate deities are very numerous, and are of both sexes; the male are worshipped by the men, and the female by the women, in separate MORALS, and under the direction of distinct priests. There are also *Mouia* common to both. Hawkes. Voyages, vol. ii. p. 239.

EAU DE LUCE, is a kind of volatile liquid soap, of a strong, penetrating smell. The following instructions will serve for making it: take four ounces of rectified spirit of wine, and in it dissolve ten or twelve grains of white soap; filtrate this solution; then dissolve in it a dram of rectified oil of amber, and filtrate again: mix as much of this solution with the strongest volatile spirit of sal ammoniac, in a crystal glass bottle, as when sufficiently shook, shall produce a beautiful milky liquor. If upon its surface be formed a cream, some more of the oily spirit of wine ought to be added.

EAVES, the margin or edge of the roof of a house, being the lowest tiles, slate, or the like, which hang over the walls to throw off the waters to a distance from the wall.

EAVE-SLATH, a thick feather-edged board, generally nailed Vol. II. N° 107.

round the *eaves* of a house for the lowermost tiles, slate, or slingles, to rest upon.

EAVE-DROPPERS, in *Law*, are persons who listen under walls or windows, or the *eaves* of a house, to overhear after discourse, and thereupon to frame slanderous and malicious tales. These are a common nuisance, and punishable at the court-leet, or midleale of the quarter-sessions, and punishable by fine, and finding sureties for good behaviour.

EBBING, and FLOWING of the Sea. See TIDES.

EBDOMARY, *Abbas*, an officer anciently appointed weekly in cathedral churches, to supervise the regular performance of divine service, and prescribe the particular duties of each person attending in the choir, as to reading, singing, and praying. To this purpose the *ebdomy*, at the beginning of his week, drew up in form, a bill or writing of the respective persons, and their several offices, called *lebens*, and the persons there entered were styled *abbedati*.

EBDOME, *Februus*, in *Antiquity*, a festival kept on the seventh of every lunar month, in honour of Apollo, to whom all seventh days were sacred, because one of them was his birth-day; whence he was sometimes called *Ebdomeus*. For the ceremonies of this solemnity, see Pont. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 28.

EBEREMORTH, or EBEREMORT, in our *Old Law*, the same as *Abemormuth*, or *abemormuth*. See ABERMURDER.

EBEREMURDRUM, or ABEREMURDRUM, in our *Old Law*. See ABERMURDER.

EBIONITES, ancient heretics, who rose in the church in the very first age thereof, and formed themselves into a sect in the second century, denying the divinity of Jesus Christ.

Origen takes them to have been so called from the Hebrew word *ebion*, which in that language signifies *poor*; because, says he, they were poor in sense, and wanted understanding. Eusebius, with a view to the first etymology, is of opinion, they were thus called, as having poor thoughts of Jesus Christ, taking him for no more than a mere man.

It is more probable the Jews gave this appellation to the Christians in general, out of contempt; because in the first times there were few but poor people that embraced the Christian religion. This opinion, Origen himself seems to give into, in his book against Celsus, where he says, that they called *Ebionites*, such among the Jews as believed that Jesus was truly the expected Messiah.

It might even be urged, with some probability, that the primitive Christians assumed the name themselves, in conformity to their profession. It is certain, Epiphanius observes, they valued themselves on being poor, in imitation of the apostles. The same Epiphanius, however, is of opinion, that there had been a man of the name *Ebion*, the chief and founder of the sect of *Ebionites*, contemporary with the Nazarenes and Cerinthians. He gives a long and exact account of the origin of the *Ebionites*, making them to have risen after the destruction of Jerusalem, when the first Christians, called *Nazarenes*, went out of the same to live at Pella.

The *Ebionites* are little else than a branch of Nazarenes; only that they altered and corrupted, in many things, the purity of the faith held among these first adherents to Christianity. For this reason, Origen distinguishes two kinds of *Ebionites*, in his answer to Celsus; the one believed that Jesus Christ was born of a virgin; and the others, that he was born after the manner of other men. The first were orthodox in every thing, excepting that the Christian doctrine they joined the ceremonies of the Jewish law, with the Jews, Samaritans, and Nazarenes; together with the traditions of the Pharisees. They differed from the Nazarenes, however, in several things, chiefly as to what regards the authority of the sacred writings; for the Nazarenes received all for scripture contained in the Jewish canon; whereas the *Ebionites* rejected all the prophets, and held the very names of David, Solomon, Isaiah, Jeremiah, and Ezeiel, in abhorrence. They also rejected all St. Paul's Epistles, whom they treated with the utmost disrespect.

They received nothing of the Old Testament but the Pentateuch, which should inform them to have descended rather from the Samaritans than from the Jews. They agreed with the Nazarenes in using the Hebrew Gospel of St. Matthew, or, as we called the Gospel of the Twelve Apostles; but they had corrupted their copy in abundance of places; and particularly, in that concerning the genealogy of our Saviour, which was preserved entire in that of the Nazarenes, and even in those used by the Cerinthians.

Some, however, have made this gospel canonical; and

of greater value than our present Greek Gospel of St. Matthew. See NAZARENE. These last, whose sentiments, as to the birth of our Saviour, were the same with those of the Ebionites, built their error on this very genealogy.

Beside the Hebrew Gospel of St. Matthew, the Ebionites had adopted several other books, under the names of St. James, John, and the other apostles; they also made use of the Travels of St. Peter, which are supposed to have been written by St. Clement, but had altered them so, that there was scarce any thing of truth left in them. They even made that saint till a number of falsehoods, the better to authorize their own practices. See St. Epiphanius, who is very diffusive on the ancient heresy of the Ebionites, *Hæc.* 30.

But his account deserves little credit, as, by his own confession, he has confounded the other sects with the Ebionites, and has charged them with errors, to which the first adherents of this sect were utter strangers.

EBOLICS, ebolicus. See ECHINOCUS.

EBONY, of Crete, Ebenus, in Botany, a genus of the *diadelphia discoloris* class. Its characters are these: the empanment of the flower is slenderly incised, and hairy; and is of the butterfly kind, having ten laminae. In the bottom is situated an oblong germin, which afterward becomes an oblong swelling pod, opening with two valves, and inclosing three or four kidney-shaped seeds. There is only one species, which grows naturally in Crete, and some other islands of the Archipelago. It rises with a shrubby stalk, three or four feet high, which puts out several side-branches, furnished with hoary leaves at each joint, composed of five narrow spear-shaped lobes, which join at their tails to the foot stalks, and spread out like the fingers of a hand: the branches are terminated by thick spikes of large purple flowers, which are of the butterfly or pea-bloom kind.

These plants will not live in the open air through the winter in England; neither should they be too tenderly treated.

EBONY of the Alps, Cyprius. See *Bals Treu-Treuil*.

EBONY, Palsi, Painsiana. See *BARRADES FLORES-PESE*.

EBONY, Alcantara. See *BAUMIA*.

EBONY wood is brought from the Indies, exceedingly hard and heavy, susceptible of a very fine polish, and on that account used in Mosiac and inlaid works, toys, &c.

There are divers kinds of *ebony*: the most usual among us are black, red, and green, all of them the product of the island of Madagascar, where the natives call them, indifferently, *baon maniki*, q. d. *black wood*. The island of St. Maurice, belonging to the Dutch, likewise furnishes part of the *ebony* used in Europe.

Authors and travellers give very different accounts of the tree that yields the black *ebony*. By some of their descriptions, it should be a tree of palm-tree; by others, acetyfied, &c. The most authentic of them is that of M. Flacourt, who resided many years at Madagascar, as governor thereof; he assures us, that it grows very high and big, its bark being black, and its leaves resembling those of our myrtle, of a deep, dusky, green colour.

Travellers assure us, that the Indians always take care to bury their trees, when cut down, to make them the blacker, and to prevent their splitting, when wrought. F. Plummer mentions another black *ebony*-tree, discovered by him at St. Domingo, which he calls *fructum particulae fœtis aculeatum ebony materice*. Candia also bears a little shrub, known to the botanists under the name of *ebony Cracca*, above described.

Phny, and Dioscorides say, the best *ebony* comes from Ethiopia, and the worst from India; but Theophrastus prefers that of India. Black *ebony* is much preferred to that of other colours. The best is jet black, free of veins and rind, very massive, stringy, and of an acid pungent taste.

Its rind, infused in water, is said to purge pituits, and cure venereal disorders; whence Mathiolus took quinquina for a sort of *ebony*. It yields an agreeable perfume, when laid on burning coals: when green, it readily takes fire, from the abundance of its fat. If rubbed against a stone, it becomes brown. The Indians make statues of their gods, and sepulchres for their princes, of this wood. It was first brought to Rome by Pompey, after he subdued Mithridates. It is now much less used among us, than anciently, since the discovery of so many ways of giving other hard woods a black colour.

As to the green *ebony*, beside Madagascar and St. Maurice, it likewise grows in the Antilles, and especially in the life of Tobago. The tree that yields it is very bushy; its leaves are smooth, and of a fine green colour. Beneath its bark is a white fleshy, about two inches thick, all beneath which, to the very heart, is a deep green, approaching towards a black, though sometimes streaked with yellow veins. Its use is not confined to mosiac

work: it is likewise good in dying, as yielding a fine green tincture.

As to red *ebony*, called also *granadillo*, we know little of it more than the name.

The cabinet-makers, inlayers, &c. make pear-tree, and other woods, pass for *ebony*, by giving them the black colour thereof. This some do by a few washes of a hot decoction of galls; and when dry, adding writing ink thereon, and polishing it with a stiff brush, and a little hot wax; and others heat, or burn, their wood black. See *DYING*.

EBRUHARITES, a sect, or order of religious, among the Mahometans; thus called from their founder *Ebruhard*, a disciple of Nacchibendi.

The *Ebruharites*, notwithstanding the extraordinary sanctity they make profession of, with an absolute dereliction of all worldly things, are regarded, by the Mussulmans, as no better than heretics, because they do not esteem themselves obliged to go in pilgrimage to Mecca. To excuse themselves from this labour, they urge, that the parents of their souls, their sublime contemplations, ecstasies, &c. show them Mecca and Mahomet's tomb, without stirring out of their cells.

EBRUCCATUM, a term used by Paracelsus, to express the partial loss, or deprivation of reason, as it happens during drunkenness; but with the addition of the epithet *calidus*, it signifies, with the same author, a much more exalted state, a sort of divine enthusiasm, or inspiration, such as the Sibyls of old boasted of; and, among the moderns, the French prophets, and some other religious sects, have pretended to. Paracelsus himself pretended, at times, to be under some such influence; but his mad fits seemed to have very little of inspiration in them.

EBRIETAS, drunkenness; among the aphorisms of Hippocrates, there is one, *aph.* which respects *ebrietas*, and is thus expressed: "If a drunken person lose his voice of a sudden, he dies in convulsions, unless a fever seizes him, or his voice returns at the going off the drunken fit."

EBRILLADE, in the *Manège*, a check of the bridle, which the horseman gives to the horse by a jerk of one rein, when he refuses to turn. An *ebriillade* differs from a *saute*, the latter being made with both reins at once, and the former only with one. Most people confound these two words under the general name of a check or jerk of the bridle, called in French *reins de bride*. It is a chastisement, and no aid, and is disused in academies.

EBRIZIUS color, a term used by some of the old writers, to express a very fine yellow. The word seems originally to have been obryzium, and was certainly derived from the *aureum ebryzum*, or fine gold, of which this *ebryzius* expressed the colour.

EBSEMECH, in *Chemistry*, a word used by Langius, and some other authors, for quicksilver.

EBULLITION, in *Physics*, the act of emitting bubbles, by a vehement agitation of the parts of a fluid, produced by fire, or otherwise.

Philosophers are disagreed about the cause and manner of ebullition. See *BOLLING*.

EBULLITION of the blood, *ebullitio sanguinis*, in Medicine, a term used by some of the old writers, to express what they supposed to be the occasion of the motion of the heart, which they attributed to a sort of ebullition of the blood contained there. See *BLOOD*.

EBULLITION, in *Chemistry*, &c. is used for a violent intestine motion, or colligation of parts, occasioned by the mixture of fluids of different nature.

Dr. Harris will have it properly and immediately, to signify that particular frugile or effervescence, arising upon the mingling together of an acid and alkaline liquor.

Mr. Boyle has an experiment to shew, that a considerable ebullition may be produced by such a mixture, without the bodies acquiring any heat; nay, that a degree of cold may be produced with it, greater than was in either of the bodies singly, though accompanied with a great frugile, tumult, noise, and froth. For, having shook one part of oil of vitriol into twelve parts of common water, the mixture was at first sensibly warm; then the ball of a thermometer was placed in it, till the included spirit had gained the temperance of the mixture; but then a convenient quantity of volatile salt of sal armoniac being gradually put in to satiate the acid spirit of the mixture, the spirit in the thermometer descended above an inch.

EBULUS, the dwarf-elder, in *Medicine*. This is a troublesome weed in many of our fields, and called, dancowort, and walwort. The leaves may be distinguished from those of the elder-tree, by their having nine, eleven, or thirteen lobes to each leaf, which are long, narrow, and very slightly indented on their edges; whereas the leaves of the common elder have seldom more than five, which are broader and shorter. The roots and leaves of dwarf-

elder are said to be bristly. The juice of this plant has been recommended in the dropsy, gout, and febrile disorders. The flowers are esteemed sudorific; and the leaves boiled till perfectly soft, make a good cataplasim for the *furcula*. See *ELDON*.

ELDER, *spina*, in Natural History. See *Fossile IVORY*.

ELDER *fossile*, variegatum, in the *Natural History* of the ancients, a name given to the substance which we now call the rough or native turquoise.

Fossile ivory, and the bones of other animals, are frequently found buried at great depths in the earth, and are found to have preserved their substance, texture, and colour in different degrees, according to the nature of the matter they happen to have lain among. Sometimes they are firm and solid, and scarce altered in colour; and sometimes more or less hardened, and tinged to different colours by the different matters in which they have been deposited.

Of this kind was the spotted fossil ivory of the ancients, which was in all respects the same with our rough turquoise of many places; which are no other than the teeth and bones of animals accidentally lodged in the way of particles of copper. See *TURQUOISE*.

ECACUATE, in *Zoology*, a name by which the natives of some parts of America call the *Rattle-SNAKE*.

ECALLESIA, *Yacchos*, in *Antiquity*, a festival kept in honour of Jupiter, furnished *Hemuli*, or *Heulhus*, from *Heali*, one of the borough-towns in Attica.

ECARTELE, in *Heraldry*. See *QUARTERLY*.

ECASTOR, in *Antiquity*, an oath wherein Castor was invoked. It was a custom for the men never to swear by Castor, nor the women by Pollux.

ECATESIA, *Yacchos*, in *Antiquity*, an anniversary solemnity, observed by the Stratoniceans, in honour of Hecate.

The Athenians likewise had a public entertainment, or supper, every new moon in honour of the same goddess. The supper was provided at the charge of the richer sort; and was no sooner brought to the accustomed place, but the poor people carried all off, giving out, that Hecate had devoured it. For the rest of the ceremonies observed on this occasion, see *Pott. Arch. Græc. lib. ii. cap. 20*.

ECATHEA, *Ecathia*, in *Antiquity*, statues erected to the goddess Hecate, for whom the Athenians had a great veneration, believing that she was the overruler of their families, and that she protected their children. *Pott. Arch. Græc. lib. ii. cap. 20. tom. i. p. 386*.

ECATOMBEON, *Ecatombeon*, in *Chronology*, the first month of the Athenian year. It consisted of thirty days, and began on the first new moon after the summer solstice, and consequently answered to the latter part of our June and beginning of July. The Boeotians called it *Hippodromi*, and the Macedonians *Leu*. See *MONTH*. The word is a derivative from the Greek *ecatombe*, a hecatomb, because of the great number of hecatombs sacrificed in it.

ECAVESSADE, in the *Mange*, is used for a jerk of the cavesson.

ECBASIS, *Ecasis*, in *Rhetoric*, is used for a digression.

ECBOLE, *Ecbole*, in *Rhetoric*, is also used for a digression.

ECBOLICS, *ecbolica*, from *ecbole*, *I ejcti*, in the writings of the ancient physicians, a term used to express such medicines as were given to promote delivery in childbirth; and also such as caused abortion. See *DELIVERY*.

ECBRASMATATA, from *ecbrasa*, *I caute laeti*, in the writings of some of the earlier physicians, a word used to express eruptions, or pustules, of a fiery and inflamed nature, appearing on different parts of the body. Virgil calls these *ardentes papule*, and seems to attribute them to the wearing cloths made of the wool of sheep which had died of a murrain, which he describes.

ECBRYSOMATA, from *ecbrusa*, *I caustice spread*, a word used by Galen, and the old physicians, for those emenences or protuberances of the bones at the joints, which appear through the skin.

ECANTHIS, or **ECANTHIS**, in *Medicine*. See *EXCANTHIS*.

ECANTHARTICS, a name given by different writers in *Medicine*, to medicines of different kinds, and producing very different effects. See *CATRARTIC*.

ECCE-HOMO, among *Painters*, a name given to a picture, wherein our Saviour is represented in a purple robe, with a crown on his head, and a reed in his hand, such as he was presented before Pilate by the Jews.

The phrase is Latin, borrowed from the words of the Jews themselves; q. d. this is the man.

ECCE-TRICITY. See *EXCENTRICITY*.

ECCHYMOSIS, *Ecchymosis*, the effusion of blood from a rupture in some of the small veins near the skin, causing a lividity or blueness thereof.

This is also called *ecchymosis*, *ecchymosis*, and stands distinguished from the *embryosis*, where there is no extravasation.

The *ecchymosis* is either *simple*, or with *abscess*. The former is a mere effusion of the skin, wherein the blood extravasated by some blow, or contusion, upon its arrival between the fleshy or muscular parts and the cutis, stops there, and turns black or livid, without any appearance of a wound. In the latter, the extravasated blood suppurates, and breeds an imposthume.

An *ecchymosis*, or extravasation of blood under the skin, is an accident too common, after bleeding in the arm. This sometimes is so violent in degree, that the arm after swelling and becoming black and blue, is violently inflamed, with acute pain, and either a suppurates or beginning mortification. This accident frequently happens from the vein's having been cut quite asunder in the operation, but often by the patient's using the arm too soon after bleeding, in violent and long exercises, in which the contractions of the muscles make the veins swell, and force their blood through the orifice into the interstices between the flesh and skin.

In slight accidents of this kind there is no danger, the flagging blood being easily dispersed by a compress dipped in vinegar and salt, or in spirit of wine. And sometimes it suppurates, and, making its way through the integuments, becomes naturally discharged, and the wound will heal with a discoloured pucker. But where the quantity of extravasated blood is large, there is no hope of its being dispersed so easily, but the disorder generally terminates in an abscess or gangrene. To prevent these accidents, the surgeon's business is to fix the livid part, and apply warm fomentations. Heister's Surgery, p. 285.

ECCLESIA, a Latin, or rather Greek term, signifying Church.

In our ancient law-books, Fitzherbert observes, that *Ecclesia*, *Yacchos*, properly signifies a *parish*. Whence, if a presentation were made to a chapel, as to a church, by the name of *ecclesia*, it changed the name thereof, and it presently commenced a church.

When the question was, Whether it were *ecclesia*, *aut ecclesia parochialis ad ecclesiam* the issue was, Whether it had *parochiam* & *parochiam*. For if it had the administration of the sacraments and discipline, it was in law judged a church. See *CHAPEL*.

ECCLESIA, *Resurrection ecclesialis*. See *RESURRECTION*.

ECCLESIA, *Resurrection ecclesialis*. See *RECTO*.

ECCLESIA, *Ward*. See *WARD*.

ECCLESIA SCULPTURA, the image or sculpture of a church in ancient times was often cut out in plate or other metal and preserved as a religious treasure or relique; and to perpetuate the memory of some famous churches.

ECCLESIALS, **ECCLESIALS**, in *Church History*. Upon any falling out, or misunderstanding, between the emperors and the churchmen, the adherents to the emperor called such as adhered to the interests of the church and churchmen, *ecclesiastici*, a term of reproach, answering to our high-church men.

ECCLESIASTES, one of the books of the Old Testament; thus called, by a Greek word, signifying *preacher*; because the author in it declaims, or preaches, against the vices and vanities of the world.

This is Marlian's judgment: Grotius thinks otherwise; taking the book to derive its appellation from its being a collection of fine sentences and reflections on the vanity of the things of our earth, &c. from the word *vanitas*, which signifies to *emiss* or *sollicit*, *vanitas*. Some Hebrew doctors, supposing the same etymon, will have it to have been thus called on account of its *emiss* a great deal of wisdom; others, because the author's aim is to *assemble* and *call together* all such as are willing to consult their safety, and avoid the dangers of the world, which is the opinion of Grotius. Lastly, others, with Calovius, deduce it from his *affirming* them about him, as a preacher *assembles* his auditors.

There are different sentiments as to the author of this book: the most common is, that it is Solomon's, who is supposed to have wrote it towards the close of his life, to give tokens of his penitence to posterity.

Grotius, indeed, takes the work to be posterior to Solomon, and to have been wrote after his death, by six authors unknown, who, to give their book the greater authority, put Solomon's name to it, and represented him as repentant. What he chiefly founds his opinion on, is, that we meet with words in this book, which are no where else seen, but in Daniel, Ezechiel, and the Chaldee paraphrases; but it is certain, all Hebrews, Greeks, and Latins, have always took it to be a work of Solomon. Indeed there are authors who have attributed all the books of Solomon to Hushai; but these are only to be understood as if that prophet

ECHENEIS, in *Icthyology*. The ancients have used this as the name of the peromysus, of some kinds; and Apian, in particular, plainly means by it our common lamprey. See REMORA.

ECHINUS. See ECHINIVS.

ECHINUS, in *Natural History*, a name given, by some authors, to the several kinds of opilids, or scorpion-stone, from *echine*, a spiny, or sharp.

ECHINATE fishes, are such as are prickly and rough, like the coat of a chestnut; or, as some say, like the skin of a hedge-hog.

ECHINI *scyllarum*. It is a very remarkable observation of Agullino Scilla, that all those fossil *echini* which he had found in the Melitense and Calabrian hills, and about Malta, were, when bruised, as was frequently the case, always bruited by a perpendicular pressure. See ECHINIVS.

ECHINI *spatagi*. It is observed, that the fossil *echini spatagi* are very frequent in the island of Malta, and people who are for having all fossil shells to be real terrestrial bodies, produced of seeds in the earth, and never to have been parts of real animals, object to these having ever been fish; their being found so plentifully in this fossil state, and so rarely in the native or recent one. This is no objection of weight; because the *corvus ammonis* give a much stronger, which are a more common fossil, and have never been found recent at all. This is no argument of weight, however, since it is easy to conceive, that the sea, at the time of the universal deluge, might throw up shells from its deep bottom, which we never can get at in fishing or otherwise. And Scilla has proved the insubstantiality of the objection, in regard to the *echini spatagi*, and shewn that those people who raised it, have been led into it by their ignorance. For he has affirmed, that they may be picked up by hundreds at a time in the port of Messina, and that himself once took up more than a hundred recent ones in an hour.

The fossils of this species, found fossil in the island of Malta, are very frequently full of the marie, of which the upper stratum of that island consists; and some of them are cracked, and have been depreised a little inward. This is an evident proof that they once were real shells, having, in this case, given way, as far as the included marie would let them, on the pressure of some external force. See *Tab. III. of shells*, N^o 24.

ECHINITES, or **ECHINITES**, in *Natural History*, the name given by authors to the fossil shells of the several species of *echini marini*, and to the stones formed in them. Of these there is almost an endless variety in the fossil world. Many of those which we daily find in our chalk-pits are the same with those now known to us in their recent state, or living in the sea; but we have numbers of others, of which our imperfect knowledge of the animal world gives us no certain account, in their recent state.

The shells of some of these are found scarce at all altered from their original condition. In many others we have placed fear-filling the pieces of the shells, and retaining every lineament of them. But their most frequent appearance is in the form of masses of hard flint, or other stone, which have been cast and formed in them, having been received, while in a fluid state, into the hollow of the shell, and therefore retaining all the lineaments of the inner surface. And, not infrequently, these also are coated over with a sparry or flinty matter, supplying the place of the shell they were formed in; and having been made, by the insensible deposition of hard matter, in the place of the particles of the shell insensibly walking away; these retain all the lineaments of the outer part of the shell, as the former flint does of the inner one. Sometimes pure crystal is found in the place of flint in these, and often crystal, but slightly defaced by earth; and these make very elegant specimens.

The various genera of fossil *echini*, or *echinites*, are usually known among authors by the names of *spatagi*, *cardati*, *galeati*, *pluvati*, *discoides*, *ovarii*, *pentastylides*.

What is generally understood by the word *echinites*, is a sort of arched shells, or stones formed in them, covered with divers eminences and cavities, some of which are disposed into beautiful lines, diverging from the summit; and always having two apertures, the one for the mouth, the other for the anus of the animal. Of these,

The *echini cardati* are such as have a remarkable furrow on one side, or end, which is usually broader than any other part of the body, and by means of this furrow, represents, in some degree, the figure of a heart on cards.

The *echini pluvati* are such as have the basis somewhat oblong, and the apertures, one in the very margin, and the other next the margin, on the opposite side. The *pluvati* and *discoides*, are subdivisions of this kind.

The *pluvati* are higher, and approach to a conic figure. The *discoides* are flatter, and more compressed.

The *ovarii* have only one aperture, at the base, and have large and unequal tubercles and papillae.

Vol. II. N^o 107.

The *pentastylides* have rows of short lines, which are so disposed as to represent a cinquefoil leaf.

The *spatagi* is a very comprehensive term, taking in most of the others as subdivisions. It comprehends all that have two apertures in the base, and that are covered with small tubercles. See *Tab. III. of Echini*, Class 9.

ECHINODERMA, in *Natural History*, the name of the sea animal more commonly known by the name of the *echini marini*, or sea hedge-hog. These are fish living in an arched shell, of various figures, according to the various species; and always, besides a vast number of smaller protuberances and cavities, having two remarkable apertures, the one serving for the mouth, the other for the anus of the animal; which are variously placed in the different genera and species.

There are yet wanting, in natural history, the proper characters and distinctions of testaceous and testaceous fishes, and, till these are fixed, there is no laying whether these creatures belong to the testaceous or crustaceous tribe.

Many affirm that the spines of the *echini* serve them in the place of legs; but there are many who deny this; and some affirm, that they have, in the living fish, found legs in another part, added not to the shell, but to the body of the animal. Klein, *Echinod.* p. 4. See **CENTRONIA**.

As to its medical virtues, it is friendly and beneficial to the stomach and belly; and provokes urine. The crude shell troated is a good ingredient in medicines for absterging the plica; and the ashes of it when burnt, cleanse foul ulcers, and repress proud flesh.

ECHINOMETRA, a name given by some to the several depreised species of the *echinodermata*. See *Tab. of Testaceous Animals*, N^o 15, 16, 17, and **ECHINODERMA**.

ECHINOPHORA, in *Botany*. See **PRICKLY PEAR**.

ECHINOPHORA, in *Icthyology*, a name given by Rondeletius to a species of sea-fish, of the round-mouthed kind, or class of the cochleari lures.

He calls it *echinophora*, because it is all over beset with tubercles; but this is a very ill chosen name, as it confounds it with the *echini* or sea-eggs; he had much better have called it *cochleari tubercula*. See **LUVARIS Cochleari**.

ECHINOPHTHALMIA, in the works of the ancient writers on *Medicine*, the name of a disease, which was an inflammation on that part of the eye-bell, which is beset with hairs, or on which the eye-lashes grow.

ECHINOPS, in *Botany*. See **GLOBE THISTLE**.

ECHINUS, in *Architecture*, a member or ornament, near the bottom of the Ionic, Corinthian, and Composite capitals; which from its circular form or contour, is called by the French, *quart de rond*, and by the English, *quarter round*, or *imbrin*; and from its being usually carved, or cut, with figures of eggs, &c. it is called also by the Latins, *ovum*, by the Italians, *ovale*; the French, *oeuf*, and the English, *egg*, and *anchora*. See *Tab. Archit.* fig. 5. Lastly, the eggs being encompassed with a cover, and thus bearing some resemblance to a chestnut cast open, the Greeks have called it *αγκυρα*, *anchora*, a word which denotes the prickly cover of a chestnut.

ECHINUS, is also used by some botanists for the prickly head, or top of any plant; thus called from its likeness to a hedge-hog, or the cover of a chestnut.

ECHINUS, the hedge-hog, and **ECHINUS marinus**, the sea-urchin. See **HEDGE-HOG**, **ECHINODERMA**, and **CENTRONIA**.

ECHIQUETE, in *Heraldry*. See **CHECKY**.

ECHITES, in *Botany*, a genus of the *pentastylides* marginia class. The characters of this genus are, that it is twined, that it has two long straight leaves, a downy seed, and a funnel-shaped flower. There are eleven species.

ECHUM, in *Botany*. See **VIBURNUM Boglii**.

ECHO, or **ECHOT**, a sound reflexed, or reverberated from a solid, concave body, and so repeated to the ear. See **SOUND**, and **REFLEXION**.

This word is formed of the Greek *εχω*, *echo*, of the verb *εχον*, *echo*, I found.

The Peripatetics, who took sound for species, or image of the sonorous body, impressed on the adjoining air, account for *echo* from a reflection of that species, occasioned by its meeting some obstacle in the way. But the moderns, who know found to consist in a certain tremor, or vibration in the sonorous body communicated to the contiguous air, and by that means to the ear, give a more consistent account of *echo*.

For a tremulous body, striking on another solid body, it is evident, may be repelled without disturbing or diminishing its tremor; and consequently a *sauna* may be rekindled by the reflection of the tremulous body, or air.

But a simple reflection of the sonorous air is not enough to solve the *echo*: for then every plain surface of a solid hard body, as being fit to reflect a voice or sound, would redouble it; which we find does not hold.

To produce an *echo*, therefore, it should seem that a kind of concavation or vaulting were necessary, in order to collect, and by collecting, to heighten and increase, and afterwards reflect the sound; as we find is the case in reflecting the rays of light, where a concave mirror is used. In reality, as often as a sound strikes perpendicularly on a wall, behind which is any thing of a vault, or arch, or even another parallel wall; so it will be reverberated in the same line, or other adjacent ones.

For an *echo* to be heard, therefore, it is necessary the ear be in the line of reflection; for the person who made the sound to hear its *echo*, it is necessary he be in a perpendicular to the place which reflects it; and for a manifold or taxological *echo*, it is necessary there be a number of walls and vaults, rocks and cavities, either placed behind each other, or fronting each other.

Those murmurs in the air, that are occasioned by the discharge of great guns, &c. are a kind of indefinite *echoes*, and proceed from the vaporous particles suspended in the atmosphere, which resist the undulations of sound, and reverberate them to the ear.

A single arch, or concavity, &c. can scarce ever stop and reflect all the sound; but if there be a convenient disposition behind it, part of the sound, propagated thither being collected and reflected, as before, will present another *echo*; or if there be another concavity, opposed at a due distance to the former, the sound reflected from the one upon the other, will be tossed back again by this latter, &c.

Many of the phenomena of *echoes* are well considered by the bishop of Loughlin and Ferns, Phil. Trans. absc. vol. i. p. 508, &c. who remarks, that any sound, falling either directly, or obliquely, on any dense body, of a smooth, whether plain or arched, superficies, is reflected, or, in other words, it *echoes* more or less. The surface, says he, must be smooth, otherwise the air, by reverberation, will be put out of its regular motion, and the sound thereby broke and extinguished. He adds, that it *echoes* more or less, to show that when all things are, as before described, there is still an *echoing*, though it be not always heard; either because the direct sound is too weak to beat quite back again to him that made it, or that it does return to him, but so weak, that it cannot be discerned: or that he stands in a wrong place to receive the reflected sound, which passes over his head, under his feet, or on one side of him, and which therefore may be heard by a man standing in the place where the reflected sound does come, provided no interpolated body intercepts it; but not by him that originally made it. There can be no *echo*, unless the direct and reflex sounds follow one another, at a sufficient distance of time, or, in other words, unless the difference between the ray proceeding directly to the ear from the sounding body, and the sum of the incident and reflex phonic rays be sufficiently great; for if the reflex sound arrives at the ear before the impression of the direct sound ceases, the sound will not be doubled, but only rendered more intense. Now if we allow, that no more than nine or ten syllables can be pronounced in a second, in order to preserve the sounds articulate and distinct, there should be about the ninth part of a second between the times of their appulse to the ear; or, as sound moves about 1142 feet in a second, the above mentioned difference should be

$\frac{1142}{9} = 127$ feet; and therefore every syllable will be reflected to the ear at the distance of about seventy feet from the reflecting body; and as in the ordinary way of speaking three or four syllables are uttered in a second, the speaker, in order to have the *echo* returned as soon as they are expected, should stand about five hundred feet from the reflecting body, and so in proportion for any other number of syllables. Merenne allows for a non-syllable the distance of 66 feet; Norton 90 feet; for a disyllable 105 feet, a trisyllable 160 feet; a tetrasyllable 182 feet, and a pentasyllable 204 feet. Nat. Hist. Northampton. chap. v. p. 358.

It is plain from the above account, that *echoes* may be applied for measuring inaccessible distances. Thus, Dr. Derham, standing upon the banks of the Thames, opposite to Woolwich, observed that the *echo* of a single sound was reflected back from the houses in three seconds; consequently, the sum of the direct and reflex rays must have been $1142 \times 3 = 3426$ feet, and the half of it, or 1713 feet, the breadth of the river in that place.

Echoes may be produced with different circumstances; for, 1. A plane obstacle reflects the sound back in its due tone and loudness; allowance being made for the proportionable decrease of the sound, according to its distance.

2. A convex obstacle reflects the sound somewhat smaller, and somewhat quicker, though weaker, than it otherwise would be.

3. A concave obstacle *echoes* back the sound, bigger, slower, and also inverted; but never according to the order of words. Nor does it seem possible to contrive any single *echo*, that shall invert the sound, and repeat backwards; because, in such a case, the word last spoken, that is, which last occurs to the obstacle, must be repelled first, which cannot be. For where in the mean time should the first words hang, and be concealed; or how, after such a pause, should they be revived, and animated again into motion?

From the determinate concavity, or archedness of the reflecting bodies, it may happen that some of them shall only *echo* back one determinate note, and that only from one place.

4. The *echoing* body being removed farther off, it reflects more of the sound than when nearer; which is the reason why some *echoes* repeat but one syllable, some one word, and some many. Of these fumes are tonical, which only return a voice when modulated into some particular musical tone; and others polysyllabic.

That fine *echo* in Woodstock park, Dr. Plot assures us, in the day-time, will return very distinctly seventeen syllables, and in the night twenty. See Nat. Hist. Oxford. chap. i. p. 7.

5. *Echoing* bodies may be so contrived, and placed, as that reflecting the sound from one to the other, either directly and mutually, or obliquely and by succession, out of one sound, shall a *multiple echo*, or many *echoes*, arise.

At Rosneath, near Glasgow, in Scotland, there is an *echo* that repeats a tune played with a trumpet three times completely and distinctly. See Birch's Hist. of the Royal Society, vol. i. p. 137.

At the sepulchre of Metella, wife of Crassus, there was an *echo*, which repeated what a man said five times. Authors mention a tower at Cyalus, where the *echo* repeated seven times. There is an *echo* at Brussels, which answers fifteen times.

One of the finest *echoes* we read of is that mentioned by Bartholus, in his notes on Statius's Thebais, lib. vi. ver. 30, which repeated the words a man uttered seventeen times: this was on the banks of the Naba, between Coblenz and Bingen. Bartholus assures us, he had proved what he writes; and had counted seventeen repetitions. And whereas, in common *echoes*, the repetition is not heard till some time after hearing the word spoke, or the notes sung; in this the person who speaks, or sings, is scarce heard at all; but the repetition very clearly, and always in surprising varieties; the *echo* seeming sometimes to approach nearer, and sometimes to be farther off. Sometimes the voice is heard very distinctly, and sometimes scarce at all. One person hears only one voice, and another several; one hears the *echo* on the right, and the other on the left, &c.

Addison, and other travellers into Italy, mention an *echo* in that country, at Simonetta palace, near Milan, still more extraordinary, which will return the sound of a pistol fifty-six times, even though the air be very foggy. The *echo* is heard behind the house, which has two wings; the pistol is discharged from a window in one of these wings, the sound is returned from a dead wall in the other wing, and heard from a window in the back-front. See Addison's Trav. edit. 1738. p. 32. Milford. Voyages d'Italie. tom. ii. p. 196. edit. 1691. Phil. Trans. N° 480. p. 120.

Add that a *multiple echo* may be made, by so placing the *echoing* bodies, at unequal distances, as that they may reflect all one way, and not one on the other; by which means, a manifold successive sound will be heard; one clap of the hands like many, one ha like a laughter; one single word like many of the same tone and accent; and so one musical instrument like many of the same kind, imitating each other.

Lastly, *echoing* bodies may be so ordered, that from any one sound given, they shall produce many *echoes* different both as to tone and intension. By which means a musical room may be so contrived, that not only one instrument playing therein shall seem many of the same sort and size, but even a consort of different ones; this may be contrived by placing certain *echoing* bodies so as that any note played, shall be returned by them in 3ds, 5ths, and 8ths.

ECHO is also used for the place where the repetition of the sound is produced, or heard. This is either natural or artificial.

In *echoes*, the place where the speaker stands, is called the *intram phonicum*; and the object, or place, that returns the voice, the *extram phonicum*.

ECHO, in *Architecture*, is applied to certain vaults, and arches, most commonly of elliptical, or parabolical figures, used to redouble sounds, and produce artificial *echoes*.

The method of making an *artificial echo* is taught by the Jesuit Bianchini, in his *Echometria*, at the end of his book on the sphere.

Vitruvius tells us, that in divers parts of Greece and Italy there were brazen vessels, artfully ranged under the seats of the theatres, to render the sound of the actors' voices more clear, and make a kind of *echo*; by which means, of the prodigious multitude of persons present at those spectacles, every body might hear with ease and pleasure.

ECHO, in *Music*, pieces composed in imitation of *rebet*. Sometimes also the word *echo* stands for *piano*, intimating that the instrument, or voice, is to play or sing after a soft and sweet manner. Organs and harpsichords have what they call an *echo* stop.

ECHO, in *Poetry*, denotes a kind of composition, wherein the last words, or syllables, of each verse, contain some meaning, which being repeated apart, answers to some question, or other matter, contained in the verse.

Such is that famous *echo* of Erasmus, *Dissemulata conspectus in legem Ciceronis*, &c. c. 194, *offit*.

The first *echo*, in verse, according to Pasquier, is that in the Sylve of Johannes Secundus: but Pasquier is mistaken; for the ancient Greek and Latin poets have wrote *echoes*. This, Martial intimates plainly enough; when, laughing at such sorts of baubles, he says, there is nothing like them among his poems. *Nisquam Græcula quæ recantat echo*: by which, on the one side, he shews that there were Latin poets, in his time, who made *echoes*; and, on the other, that the invention came from the Greeks.

Aspidophanes, in his comedy entitled *Ἐχόμενοι*, introduces Euripides in the person of *Echo*; and Calimachus, in the epigram, *Ἐχόμενα τοῦ Ὀμήρου τοῦ ἀνδρὸς*, seems to have intended a kind of *echo*.

There is a humorous specimen of this kind of poetry in Hudibras.

ECHOMETRER, in *Music*, a kind of scale, or rule, with several lines divided thereon, serving to measure the duration, or length, of sounds, and to find their intervals and ratios.

The word is formed of the Greek *εχμετρον*, and *μετρον*, measure.

ECHOS, *ἠχὴ*, a sound, in *Physic*. In Hippocrates this frequently imports what the Latins call *tinnitus aurium*, and the English a ringing of the ears; a symptom very frequent in acute distempers.

ECHPHYAS, from *εχω* and *φυα*, I produce, an excrescence, or appendix, a word used by many of the ancient writers in medicine. The appendicula vermiformis is thus called by many authors.

ECHTHELYNISIS, from *εχθηρως*, of *δακρυς* feminine, I render effeminate, a term used by the ancient physicians for a laxness, or flabby softness, of the flesh of the legs, or any other part of the body. Some have also used the word to express a fault in bandages, when too loose.

ECLAMPISIS, from *ελαμπεω*, I shine, a word used by Hippocrates in describing the epilepsy, and, by most people, supposed, by a forced explanation, to mean the change which children undergo at the age of puberty, a time of great consequence in this disease, at which nature shines forth in new lustre, by the increase both of strength and understanding. But the more natural and obvious sense of the word seems to be the expressing of those resplendent flashings and sparkings of light which strike the eyes of persons subject to this distemper, and which are called by Celsus Aurelianus *scintillarum micæ*, and *circuli ignis*. And the same author, in describing one of his epileptic cases, particularly mentions the flashings of lightning, as it were, which were frequent before his eyes. It is not to be omitted that Hippocrates and Galen have both also used this word in another sense, to express the highest degree of a fever, just before and at the crisis, when it is in its utmost degree of heat, and exerts itself with its utmost violence.

ECLICTIC, **ECLICTICAL**, a name given to some ancient philosophers, who, without attaching themselves to any particular sect, took what they judged good, and foliow from each.

Hence their denomination; which, in the original Greek, signifies, that they were chosen, or that chosen; of the verb *ελεγομαι*, I choose.

Laetius notes, that they were also, for the same reason, denominated *analogici*; but that they call themselves *philosophi*, i. e. lovers of truth.

The chief, or founders, of the *eclectic*, was one Potamon, of Alexandria, who lived under Augustus and Tiberius; and who, weary of doubting of all things with the Sceptics and Pyrrhonians, formed the *eclectic* sect; which Vollius calls the *reluctive*.

Towards the close of the second century a sect arose in

the Christian church under the denomination of *Eclectici*, or modern *Platonici*. They professed to make truth the only object of their enquiry, and to be ready to adopt, from all the different systems and sects, such tenets as they thought agreeable to it. However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who at this time laid the foundation of that sect, afterwards distinguished by the name of the new *Platonici*, in the Alexandrian school. This philosopher was born of Christian parents, and educated in the Christian faith, and probably never deserted the outward profession of this religion; though Porphyry maintains, in opposition to the testimony of Eusebius, that in mature life he became a pagan; and Fabricius, who is followed by Dr. Lardner, alleges that there were two persons of the same name, the one a heathen philosopher, and the other a Christian writer. Those who are desirous of acquainting themselves with the grounds of their opposite opinions, may consult Fabricius's Bibl. Græc. lib. iv. cap. 26, p. 159. Lardner's Collection of Jewish, and Heathen Testimonies, vol. iii. p. 195, &c. and Meisheim, De Rebus Christianorum ante Const. Mag. p. 281, &c.

It was evidently the design of Ammonius to reconcile and unite all sects, philosophical and religious, and to inculcate a doctrine that should comprehend all, the Christians not excepted, in one common profession. For this purpose he maintained, that the great principles of all philosophical and religious truth were to be found, equally, in all sects; that they differed from each other, only in their method of expressing them, and in some opinions of little or no importance; and that, by a proper interpretation of their respective sentiments, they might easily be united into one body. Accordingly, all the gentle religions, and even the Christian, were to be illustrated and explained by the principles of this universal philosophy; and the fables of the priests were to be removed from paganism, and the comments and interpretations of the disciples of Jesus from Christianity. In conformity to this plan he insisted, that all the religious systems of all nations should be referred to their original purity, and reduced to their primitive standard, viz. the ancient philosophy of the East, preserved uncorrupted by Plato; and he affirmed that this project was agreeable to the intentions of Jesus Christ, whose sole view, in descending upon earth, was to set bounds to the reigning superstition, to remove the errors that had blinded themselves with the religions of all nations, but not to abolish the ancient theology from which they were derived. He therefore adopted the doctrines which were received in Egypt concerning the universe, and the Deity, considered as constituting one great whole, concerning the eternity of the world, the nature of souls, the empire of Providence, and the government of the world by demons. He also established a system of moral discipline, which allowed the people in general to live according to the laws of their country, and the dictates of nature, but required the wise to exalt their minds by contemplation, and to mortify the body, so that they might be capable of enjoying the presence and assistance of the demons, and of ascending after death to the presence of the Supreme Parent. In order to reconcile the popular religions, and particularly the Christian, with this new system, he made the whole history of the heathen gods an allegory, maintaining that they were only celestial ministers, entitled to an inferior kind of worship; and he acknowledged that Jesus Christ was an excellent man, and the friend of God, but alleged that it was not his design entirely to abolish the worship of demons, and that his only intention was to purify the ancient religion. This system, so plausible in its first rise, but so comprehensive and complete in its progress, has been the source of innumerable errors and corruptions in the Christian church. At its first establishment it is said to have had the approbation of Arsenius, Pantenus, and Clemens the Alexandrian, and of all who had the care of the public school belonging to the Christians at Alexandria. It was afterwards adopted by Longinus, the celebrated author of the Treatise on the Sublime, Plotinus, Hieronymus, Origen, Porphyry, Iamblichus the disciple of Porphyry, Sopater, Eudius, Eustathius, Maximus of Ephesus, Priscus, Chrysanthus the minister of Julian, Julian the Apostate, Hierocles, Proclus, and many others, both Pagans and Christians. Meisheim's Eccl. Hist. vol. i. p. 126, &c. See. See PLATONISM.

ECLECTICS were also a certain set of physicians among the ancients, of whom Archigenes, under Trajan, was the chief, who selected from the opinions of all the other sects, that which appeared to them best, and most rational.

To produce an *echo*, therefore, it should seem that a kind of concameration or vaulting were necessary, in order to collect, and by collecting, to heighten and increase, and afterwards reflect the sound; as we find is the case in reflecting the rays of light, where a concave mirror is used. In reality, as often as a sound strikes perpendicularly on a wall, behind which is any thing of a vault, or arch, or even another parallel wall; so oft will it be reverberated in the same line, or other adjacent ones.

For an *echo* to be heard, therefore, it is necessary the ear be in the line of reflection; for the person who made the sound to hear its *echo*, it is necessary he be in a perpendicular to the place which reflects it; and for a manifold or tautological *echo*, it is necessary there be a number of walls and vaults, rocks and caverns, either placed behind each other, or fronting each other.

Those murmurs in the air, that are occasioned by the discharge of great guns, &c. are a kind of indefinite *echo*, and proceed from the vaporous particles suspended in the atmosphere, which resist the undulations of sound, and retransmit them to the ear.

A single arch, or concavity, &c. can scarce ever stop and reflect all the sound, but if there be a convenient disposition behind it, part of the sound, propagated thither being collected and reflected, as before, will present another *echo*; or if there be another concavity, opposed at a due distance to the former, the sound reflected from the one upon the other, will be tossed back again by this latter, &c.

Many of the phenomena of *echo* are well considered by the bishop of Leighton and Fersa, Phil. Trans. abt. vol. i. p. 508, &c. who remarks, that any sound, falling either directly, or obliquely, on any dense body, of a smooth, whether plain or arched, superficies, is reflected, or, in other words, it *echoes* more or less. The surface, says he, must be smooth, otherwise the air, by reverberation, will be put out of its regular motion, and the sound thereby broke and extinguished. He adds, that it *echoes* more or less, to shew that when all things are, as before described, there is still an *echoing*, though it be not always heard; either because the direct sound is too weak to beat quite back again to him that made it, or that it does return to him, but so weak, that it cannot be discerned; or that he stands in a wrong place to receive the reflected sound, which passes over his head, under his feet, or on one side of him, and which therefore may be heard by a man standing in the place where the reflected sound does come, provided no interposed body intercepts it; but not by him that originally made it. There can be no *echo*, unless the direct and reflex sounds follow one another, at a sufficient distance of time, or, in other words, unless the difference between the ray proceeding directly to the ear from the sounding body, and the sum of the incident and reflex phonic rays be sufficiently great; for if the reflex sound arrives at the ear before the impression of the direct sound ceases, the sound will not be doubled, but only rendered more intense. Now if we allow, that no more than nine or ten syllables can be pronounced in a second, in order to preserve the sounds articulate and distinct, there should be about the ninth part of a second between the times of their impulse to the ear; or, as sound moves about 1142 feet in a second, the above mentioned difference should be

$\frac{1142}{9} = 127$ feet; and therefore every syllable will be reflected to the ear at the distance of about seventy feet from the reflecting body; and as in the ordinary way of speaking three or four syllables are uttered in a second, the speaker, in order to have the *echo* returned as soon as they are expressed, should stand about five hundred feet from the reflecting body; and so in proportion for any other number of syllables. Mercurius allows for a monosyllable the distance of 69 feet; for a disyllable 105 feet, a trisyllable 160 feet, a tetrasyllable 182 feet, and a pentasyllable 204 feet. Nat. Hist. Northampton, chap. v. p. 358.

It is plain from the above account, that *echo* may be applied for measuring inaccessible distances. Thus, Dr. Derham, standing upon the banks of the Thames, opposite to Woodwich, observed that the *echo* of a single sound was reflected back from the houses in three seconds; consequently, the sum of the direct and reflex rays must have been $1142 \times 3 = 3426$ feet, and the half of it, or 1713 feet, the breadth of the river in that place.

Echos may be produced 4 with different circumstances; for, 1. A plane oblique reflects the sound back in its due tone and loudness; allowance being made for the proportionable decrease of the sound, according to its distance.

2. A *concave* oblique reflects the sound somewhat smaller, and somewhat quicker, though weaker, than it otherwise would be.

3. A *convex* oblique *echoes* back the sound, bigger, slower, and also inverted; but never according to the order of words. Nor does it seem possible to contrive any single *echo*, that shall invert the sound, and repeat backwards, because, in such a case, the word last spoken, that is, which last occurs to the oblique, must be repelled first, which cannot be. For where in the mean time should the first words hang, and be concealed; or how, after such a pause, should they be revived, and animated again into motion?

From the determinate concavity, or architude of the reflecting bodies, it may happen that some of them shall only *echo* back one determinate note, and that only from one place.

4. The *echoing* body being removed farther off, it reflects more of the sound than when nearer; which is the reason why some *echoes* repeat but one syllable, some one word, and some many. Of these some are tonical, which only return a voice when modulated into some particular musical tone; and others polysyllabical.

That fine *echo* in Woodstock park, Dr. Plot assures us, in the day-time, will return very distinctly seventeen syllables, and in the night twenty. See Nat. Hist. Oxford, chap. i. p. 7.

5. *Echoing* bodies may be so contrived, and placed, as that reflecting the sound from one to the other, either directly and mutually, or obliquely and by succession, out of one sound, shall a *multiple echo*, or many *echos*, arise.

At Roshen, near Glasgow, in Scotland, there is an *echo* that repeats a tune played with a trumpet three times completely and distinctly. See Birch's Hist. of the Royal Society, vol. i. p. 137.

At the sepulchre of Metella, wife of Crassus, there was an *echo*, which repeated what a man said five times. Authors mention a tower at Ceryces, where the *echo* repeated seven times. There is an *echo* at Brinkley, which answers fifteen times.

One of the finest *echos* we read of is that mentioned by Bartholin, in his notes on Strabo's Tiberius, lib. vi. ver. 30, which repeated the words a man uttered seventeen times: this was on the banks of the Nahs, between Coblenz and Bingen. Bartholin assures us, he had proved what he writes; and had counted seventeen repetitions. And whereas, in common *echos*, the repetition is not heard till some time after hearing the word spoke, or the notes sung; in this the person who speaks, or sings, is scarce heard at all; but the repetition very clearly, and always in surprising varieties, the *echo* seeming sometimes to approach nearer, and sometimes to be farther off. Sometimes the voice is heard very distinctly, and sometimes scarce at all. One person hears only one voice, and another several; one hears the *echo* on the right, and the other on the left, &c.

Addison, and other travellers into Italy, mention an *echo* in that country, at Simonetta palace, near Milan, still more extraordinary, which will return the sound of a pistol fifty-six times, even though the air be very foggy. The *echo* is heard behind the house, which has two wings; the pistol is discharged from a window in one of these wings, the sound is returned from a dead wall in the other wing, and heard from a window in the back-front. See Addison's Trav. edit. 1718. p. 32. Milford Voyag. d'Ital. tom. ii. p. 196. edit. 1691. Phil. Trans. N° 480. p. 220.

Add, that a *multiple echo* may be made, by so placing the *echoing* bodies, at unequal distances, as that they may reflect all one way, and not one on the other; by which means, a manifold successive sound will be heard; by one clap of the hands like many, one *ho* like a laughter; one single word like many of the same tone and accent; and so one musical instrument like many of the same kind, imitating each other.

Lastly, *echoing* bodies may be so ordered, that from any one sound given, they shall produce many *echos* different both as to tone and intension. By which means a musical room may be so contrived, that not only one instrument playing therein shall seem many of the same sort and size, but even a consort of different ones: this may be contrived by placing certain *echoing* bodies so as that any note played, shall be returned by them in 3ds, 5ths, and 8ths.

ECHO is also used for the place where the repetition of the sound is produced, or heard. This is either natural or artificial.

In *echos*, the place where the speaker stands, is called the *centrum phonorum*; and the object, or place, that returns the voice, the *centrum phonocaptivum*.

ECHO, in *Architecture*, is applied to certain vaults, and arches, most commonly of elliptical, or parabolical figures; used to redouble sounds, and produce artificial *echos*.

The method of making an artificial *echo* is taught by the Jesuit Blancani, in his *Echometria*, at the end of his book on the Sphere.

Vitruvius tells us, that in divers parts of Greece and Italy there were brazen vessels, artfully ranged under the seats of the theatres, to render the sound of the actors' voices more clear, and make a kind of *echo*, by which means, of the prodigious multitude of persons present at those spectacles, every body might hear with ease and pleasure.

ECHO, in *Music*, pieces composed in imitation of *echo*. Sometimes also the word *echo* stands for *piano*, intimating that the instrument, or voice, is to play or sing after a soft and sweet manner. Organs and harpsichords have what they call an *echo* stop.

ECHO, in *Poetry*, denotes a kind of composition, wherein the last words, or syllables, of each verse, contain some meaning, which being repeated apart, answers to some question, or other matter, contained in the verse.

Such is that famous *echo* of Erasmus, *Dum assis infans in legibus Cicero*—see, l. c. vii. *offic.*

The first *echo*, in verse, according to Pasquier, is that in the *Sylve* of Johannes Secundus: but Pasquier is mistaken; for the ancient Greek and Latin poets have wrote *echoes*. This, Martial intimates plainly enough; when, laughing at such sorts of baubles, he says, there is nothing like them among his poems. — *Nupseram Græculis quod narrant echo*: by which, on the one side, he shews there were Latin poets, in his time, who made *echoes*; and, on the other, that the invention came from the Greeks.

Aristophanes, in his comedy entitled *Quænegævæcoris*, introduces Euripides in the person of *Echo*; and Callicrates, in the epigram, *Echæus æt æchæus æt æchæus*, seems to have intended a kind of *echo*.

There is a humorous specimen of this kind of poetry in Hudibras.

ECHOMETR, in *Music*, a kind of scale, or rule, with several lines divided thereon, serving to measure the duration, or length, of sounds, and to find their intervals and ratios.

The word is formed of the Greek *εχμετρον*, and *μετρον*, measure.

ECHOS, *ἠχὴ*, a sound, in *Physic*. In Hippocrates this frequently imports what the Latins call *truncus aurium*, and the English a ringing of the ears; a symptom very frequent in acute distempers.

ECHPHYAS, from *εχ* and *φυα*, I produce, an excrescence, or appendix, a word used by many of the ancient writers in medicine. The appendicula vermiciformis is thus called by many authors.

ECHTHELYNSIS, from *εχθηρως* of *δακρυς*, feminine, I render effeminate, a term used by the ancient physicians for a laxness, or flabby softness, of the flesh of the legs, or any other part of the body. Some have also used the word to express a fault in bandages, when too loose.

ECLAMPSIS, from *εκλαμπω*, I shine, a word used by Hippocrates in describing the epilepsy, and, by most people, supposed, by a forced explanation, to mean the change which children undergo at the age of puberty, a time of great consequence in this disease, at which nature flings forth in new lustre, by the increase both of strength and understanding. But the more natural and obvious sense of the word seems to be the expressing of those resplendent flashings and sparkings of light, which strike the eyes of persons subject to this distemper, and which are called by Celsus Aurelianus *scintillarum micæ*, and *circuli ignis*. And the same author, in describing one of his epileptic cases, particularly mentions the flashings of lightning, as it were, which were frequent before his eyes. It is not to be omitted that Hippocrates and Galen have both also used this word in another sense, to express the highest degree of a fever, just before and at the crisis, when it is in its utmost degree of heat, and exerts itself with its utmost violence.

ELECTIC, *Ελεκτικός*, a name given to some ancient philosophers, who, without attaching themselves to any particular sect, took what they judged good, and solid, from each.

Hence their denomination; which, in the original Greek, signifies, that they were chosen, or that *electus*, of the verb *ελεγω*, I choose.

Lucretius notes, that they were also, for the same reason, denominated *analystæ*; but that they call themselves *philosophes* i. e. lovers of truth.

The chief, or founder, of the *electic*, was one Potamon, of Alexandria, who lived under Augustus and Tiberius; and who, weary of doubting of all things with the Sceptics and Pyrrhonians, formed the *electic* sect; which Volius calls the *reluctive*.

Towards the close of the second century a sect arose in

the Christian church under the denomination of *Electici*, or modern *Platonici*. They professed to make truth the only object of their enquiry, and to be ready to adopt, from all the different systems and sects, such tenets as they thought agreeable to it. However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who at this time laid the foundation of that sect, afterwards distinguished by the name of the new *Platonici*, in the Alexandrian school. This philosopher was born of Christian parents, and educated in the Christian faith, and probably never deserted the outward profession of this religion; though Porphyry maintains, in opposition to the testimony of Eusebius, that in mature life he became a pagan; and Fabricius, who is followed by Dr. Lardner, alleges that there were two persons of the true name, the one a heathen philosopher, and the other a Christian writer. Those who are desirous of acquainting themselves with the grounds of these opposite opinions, may consult Fabricius's *Bibl. Græc.* lib. ix. cap. 26, p. 153. Lardner's *Collection of Jewish, and Heathen Testimonies*, vol. iii. p. 105, &c. and Mosheim, De *Rebus Christianorum ante Const.* Mag. p. 281, &c.

It was evidently the design of Ammonius to reconcile and unite all sects, philosophical and religious, and to inculcate a doctrine that should comprehend all, the Christians not excepted, in one common profession. For this purpose he maintained, that the great principles of all philosophical and religious truth were to be found, equally, in all sects; that they differed from each other, only in their method of expressing them, and in some opinions of little or no importance; and that, by a proper interpretation of their respective sentiments, they might easily be united into one body. Accordingly, all the gentile religions, and even the Christian, were to be illustrated and explained by the principles of this universal philosophy; and the fables of the priests were to be removed from paganism, and the comments and interpretations of the disciples of Jesus from Christianity. In conformity to this plan he insisted, that all the religious systems of all nations should be referred to their original purity, and seduced to their primitive standard, viz. the ancient philosophy of the East, preferred uncorrupted by Plato; and he affirmed that this project was agreeable to the intentions of Jesus Christ, whose sole view, in descending upon earth, was to set bounds to the reigning superstition, to remove the errors that had blinded themselves with the religions of all nations, but not to abolish the ancient theology from which they were derived. He therefore adopted the doctrine which were received in Egypt concerning the universe, and the Deity, considered as constituting one great *universe*, concerning the eternity of the world, the nature of souls, the empire of Providence, and the government of the world by demons. He also established a system of moral discipline, which allowed the people in general to live according to the laws of their country, and the dictates of nature, but required the wise to exalt their minds by contemplation, and to mortify the body, so that they might be capable of enjoying the presence and assistance of the demons, and of ascending after death to the presence of the Supreme Parent. In order to reconcile the popular religions, and particularly the Christian, with this new system, he made the whole history of the heathen gods an allegory, maintaining that they were only celestial ministers, entitled to an inferior kind of worship; and he acknowledged that Jesus Christ was an excellent man, and the friend of God, but alleged that it was not his design entirely to abolish the worship of demons, and that his only intention was to purify the ancient religion. This system, so plausible in its first rise, but so comprehensive and compelling in its progress, has been the source of innumerable errors and corruptions in the Christian church. At its first establishment it is said to have had the approbation of Arius, Arius, Panteus, and Clemens the Alexandrian, and of all who had the care of the public school belonging to the Christians at Alexandria. It was afterwards adopted by Longinus, the celebrated author of the *Treatise on the Sublime*, Plotinus, Herennius, Origen, Porphyry, Iamblichus the disciple of Porphyry, Sopater, Eudius, Eustathius, Maximus of Ephesus, Priscus, Chrysanthus the master of Julian, Julian the Apostate, Hierocles, Proclus, and many others, both Pagans and Christians. Mosheim's *Ecl. Hist.* vol. i. p. 136, &c. See *PLATONISM*.

ELECTICS were also a certain set of physicians among the ancients, of whom Archigenes, under Trajan, was the chief, who selected from the opinions of all the other sects, that which appeared to them best, and most rational.

tional; hence they were called *ecleptici*, and their pre-
scriptions *medicina ecleptica*.

ECLIPSE, or **ECLIPSE**, *eclypsis*, or *Ecliptic*, in
Medicine, a pectoral remedy, of the consistence of a
thick syrup, called *alfo*, *alshu*, *alshur*, and *alshur*.

The word is Greek, formed of *ec*, and *lypsis*, to be
lacking; the patient is to take it off by licking it off the end
of a liguorice stick, dip therein, in order that, being
taken thus by little and little, it may remain the longer
in the passage, and moisten the breast the better.

There are *eclypsis* of the syrinx of poppy, others of len-
tils, others of squills, &c. Their intention is to heal or
ease the lungs, in coughs, peripneumonies, &c. They
are usually composed of cast, incorporated with syrinx.

ECLIPSE, in *Astronomy*, is an instrument invented
by Mr. Ferguson for exhibiting the time, quantity, du-
ration, and progress of solar eclipses, at all parts of the
earth. This machine consists of a terrestrial globe A,
(*Tab. II. Astronom.*, fig. 36.) turned, by a wheel M, round
its axis B, inclining 23½°, and carrying an index round
the hour-circle D; a circular plate E, on which the
months and days of the year are inscribed, and which
supports the globe in such a manner, that when the
given day of the month is turned to the annual index
G, the axis has the same position with the earth's axis at
that time; a crooked wire F, which points to the mid-
dle of the earth's enlightened disc, and shows to what
place of the earth the sun is vertical at any given time;
a penumbra, or thin circular plate of brass I, divided
into 12 digits, by 12 concentric circles, and so propor-
tioned to the size of the globe, that its shadow, formed
by the sun, or a candle placed at a convenient distance,
with its rays transmitted through a convex lens, to make
them fall parallel on the globe, may cover those parts
of the globe, which the shadow and penumbra of the
moon cover on the earth; an upright frame HHHH,
on the sides of which are scales of the moon's latitude,
with two sliders K and K fitted to them, by means of
which the centre of the penumbra may be always ad-
justed to the moon's latitude; a solar horizon C, divid-
ing the enlightened from the darkened hemisphere, and
showing the places where the general eclipse begins and
ends with the rising or setting sun; and a handle N,
which turns the globe round its axis by wheel work, and
moves the penumbra across the frame by threads over the
pulleys L, L, L, with a velocity duly proportional to
that of the moon's shadow over the earth, as the earth
turns round its axis.

If the moon's latitude at any conjunction exceeds the
number of divisions on the scales, there can be no eclipse;
if not, the sun will be eclipsed to some parts of the
earth; the appearances of which may be represented by
the machine, either with the light of the sun, or of a
candle. For this purpose, let the indexes of the sliders
KK point to the moon's latitude, the plate E be turned
till the day of the given new moon comes to G, and the
penumbra be moved till its centre comes to the perpen-
dicular thread in the middle of the frame, which thread
represents the axis of the eclipses; then turn the handle
till the meridian of London on the globe comes under
the point of the wire F, and turn the hour-circle D, till
XII at noon comes to its index; and turn the handle till
the hour-index points to the time of new moon in the
circle D, and then screw fast the collar N. Lastly, ele-
vate the machine, till the sun shines through the light-
holes in the small upright plates O, O, on the pedestal;
or, place a candle before the machine, at the distance of
about four yards, so that the shadow of the intersection
of the cross thread in the middle of the frame may fall
precisely on that part of the globe to which the wire F
points; with a pair of compasses take the distance be-
tween the centre of the penumbra, and the intersection
of the threads, and set the candle higher or lower, ac-
cording to that distance; and place a large convex lens
between the machine and candle, so that the candle may
be in the focus of the lens; and thus the machine is rec-
tified for use.

Let the handle be turned backward, till the penumbra al-
most touches the side HF of the frame, and then, turn-
ing it forward, the following phenomena may be ob-
served. 1. Where the eastern edge of the shadow of the
penumbral plate I, first touches the globe at the solar hori-
zon, those who inhabit the corresponding part of the
earth see the eclipse begin on the uppermost edge of the
sun, just at the time of its rising. 2. In that place
where the penumbra's centre first touches the globe, the
inhabitants have the sun rising upon them centrally
eclipsed. 3. When the whole penumbra just falls upon
the globe, its western edge at the solar horizon touches
and leaves the place where the eclipse ends at sun-set on
his lowermost edge. 4. By continued turning, the cross
line in the centre of the penumbra will go over all those

places on the globe where the sun is centrally eclipsed.
5. When the eastern edge of the shadow touches any
place of the globe, the eclipse begins there; and when the
vertical line, in the penumbra comes to any place, then
is the greatest obscuration at that place; and when the
western edge of the penumbra leaves the place, the
eclipse ends there, and the times are shown on the hour-
circle; and from the beginning to the end, the shadows
of the concentric penumbral circles show the number of
digits eclipsed at all the intermediate times. 6. When
the eastern edge of the penumbra leaves the globe at the
solar horizon C, the inhabitants see the sun beginning to
be eclipsed on his lowermost edge at his setting. 7.
Where the penumbra's centre leaves the globe, the in-
habitants see the sun centrally eclipsed; and lastly, where
the penumbra is wholly departing from the globe, the
inhabitants see the eclipse ending on the uppermost part
of the sun's edge, at the time of its disappearing in the
horizon.

This instrument will likewise serve for exhibiting the
times of sun rising and setting, and of morning and even-
ing twilight, as well as the places to which the sun is
vertical on any day, by setting the day on the plate E to
the index G, turning the handle till the meridian of the
place comes under the point of the crooked wire F, and
bringing XII on the hour-circle D to the index; then if
the globe be turned, till the place touches the eastern
edge of the horizon C, the index shows the time of sun-
setting; and when the place comes out from below the
other edge of C, the index shows the time when evening
twilight ends; and morning twilight and sun-rising are
shown in the same manner on the other side of the globe.
And the places under the point of the wire F are those
to which the sun passes vertically on that day. *Ferguson's
Astronomy*, p. 268, &c. 4to. edit. or *Phil. Trans.*
vol. xlviii. p. 520.

ECLIPSE, from *eclypsis*, of *eclypsis*, I fail, in
Astronomy, a privation of the light of one of the lumina-
ries, by the interposition of some opaque body, either be-
tween it and the eye, or between it and the sun.

The ancients had frightful ideas of eclipses, supposing
them prodiges of the most dismal events. Plutarch al-
lures us, that at Rome, it was not allowed to talk pub-
licly of any natural causes of eclipses. They made a
great noise with broken instruments, and raised loud
shouts, during eclipses of the moon, as thinking, there-
by, to call her in labour; whence Juvenal, speaking of
a talkative woman, says, *Una hinc sonat pueri facessere
luna*. Others attributed the eclipse of the moon to the
arts of magicians, who, by their enchantments, plucked
her out of heaven, and made her skim over the grass.
The natives of Mexico kept fast, during eclipses; and
particularly their women, who beat and abuse them-
selves, drawing blood from their arms, &c. They im-
agine the moon has been wounded by the sun; in some
quarrel between them.

The Chinese fancy that eclipses are occasioned by great
dragons, who are ready to devour the sun and moon,
and therefore, when they perceive an eclipse, they rattle
drums and brass kettles, till the monster, terrified by the
noise, lets go his prey. The superstitious notions enter-
tained of eclipses were once of considerable advantage to
Christopher Columbus, when, in 1493, he was driven
on the island of Jamaica, and distressed for want of pro-
visions, was refused relief; but having threatened them
with a plague, and foretelling an eclipse, as a token of it,
which happened according to his prediction, the barba-
rians were so terrified, that they drove who should be the
first in bringing him supplies, throwing him at his feet,
and imploring forgiveness. *Keil's Alman.* vol. i.
lib. v. cap. 2. § 14, or p. 201.

ECLIPSE, the duration of an, is the time between the im-
merision and emerision.

ECLIPSE, immersion, or incidence, of an, is the moment when
part of the sun, planet, or moon's disk, first begins to be
hidden. See IMMERSION.

ECLIPSE, emersion, or emergence, of an, is the time when
the eclipsed luminary begins to re-appear, or emerge out
of the shadow.

To determine the duration of eclipses, they usually divide
the diameter of the luminary eclipsed into 12 equal parts,
called digits, or digits eclipsed.

Eclipses are divided, with respect to the luminary eclipsed,
into eclipses of the sun, of the moon, and of the planets;
and, with respect to the circumstances, into total, partial,
annular, &c. eclipses.

ECLIPSE of the moon, is a deficiency of light in the moon,
occasioned by a diametrical opposition of the earth, be-
tween the sun and moon.

The manner of this eclipse is exhibited in *Tab. Astronom.*
fig. 34. where A represents the earth, and B, or C, the
moon.

When

When all the light of the moon is intercepted, i. e. when her whole disk is covered, the eclipse is said to be *total*; when only part, *partial*; when the total eclipse lasts for some time, it is said to be *totalis cum mora*, *total with continuance*; when only instantaneous, *totalis sine mora*, *total without continuance*.

Eclipses of the moon only happen in the time of full moon; because it is only then the earth is between the sun and moon; nor do they happen every full moon, by reason of the obliquity of the moon's way with respect to the sun's; but only in those full moons which happen either in the nodes, or very near them, where the aggregate of the apparent semidiameters of the moon and the earth's shadow is greater than the latitude of the moon, or the distance between their centres.

The most considerate circumstances in the eclipses of the moon are, 1. That as the sum of the semidiameters of the moon and earth's shadow is greater than the aggregate of the semidiameters of the sun and moon (that, when least, being 51; and this, when greatest, scarce 37) it is evident, *lunar eclipses* may happen in a greater latitude of the moon, and at a greater distance from the nodes, and, consequently, are more often observed, in any one part of the earth, than *solar ones*; though, with respect to the whole earth, the latter are more frequent than the former, because the sun's ecliptic limits are greater than the moon's.

2. *Total eclipses*, and those of the longest duration, happen in the very nodes of the eclipse; because the section of the earth's shadow, then falling on the moon, is considerably greater than her disc. There may likewise be *total eclipses* within a little distance of the nodes; but the farther, the less their duration; farther off still, there are only partial ones, and, at length, none at all; as the latitude and the semidiameter of the moon, together, are either less, equal, or greater than the semidiameter of the shadow.

3. All *lunar eclipses* are universal, i. e. are visible in all parts of the globe which have the moon above their horizon; and are every where of the same magnitude, and begin and end together.

4. In all *lunar eclipses*, the eastern side is what first immerses, and also emerges; so that though, at first, the moon be more westerly than the earth's shadow, yet her proper motion being swifter than the same, she overtakes and outgoes it.

5. The moon, even in the middle of an eclipse, has usually a faint appearance of light, resembling tarnished copper; which Cassini, Riccioli, Kepler, &c. attribute to the light of the sun, refracted by the earth's atmosphere, and transmitted thither.

Lastly, she grows sensibly paler, and dimmer, before she enters within the earth's shadow; which is attributed to the earth's penumbra.

Method of lunar Eclipses; or the method of calculating their times, places, magnitudes, and other phenomena. Preliminary 1. To find the length of the earth's shadowy cone. Find the sun's distance from the earth for the given time. See SUN, and DISTANCE. Then, as the sun's diameter is known in semidiameters of the earth, the length of the cone will be found from the rule given under SHADOW. Suppose, e. g. the distance of the sun from the earth to be 95,000,000 miles, and the eccentricity of the orbit 1,377,000 miles, then will the greatest distance be 96,377,000, or 24094 semidiameters of the earth; and the sun's semidiameter to that of the earth as 112 to 1, then will the length of the shadowy cone be 217 diameters of the earth.

Or, in the triangle *abc* (Tab. II. *Astronomy*, fig. 71.) let *ab* represent the semidiameter of the sun, which at his greatest distance from the earth, whose semidiameter is *cd*, appears under the angle *acb* equal to $15^{\circ} 44'$; let the sun's parallax, or the angle *cda*, for the sake of avoiding fractions, be q' ; then will the angle *cae*, or the semi-angle of the conical shadow, be $15^{\circ} 35'$; whence in the triangle *cae*, we shall have, by trigonometry, the tangent of $15^{\circ} 35'$ to radius as *ca*, or 1 semidiameter of the earth to *ce*: i. e. by Gardiner's Logarithmic Tables, $7,6563832:10,000,000::0,000,000:1,3436168$, which is the logarithm of the number 220.6 nearly; and therefore the length of the shadow is thus found to be above 210 semidiameters of the earth. But if the parallax be neglected, and the semi-angle of the cone supposed to be $15^{\circ} 50'$, the height of the shadow will be only somewhat more than 217 semidiameters of the earth. And if we suppose the moon's shadow to be similar to that of the earth, and the proportion of their semidiameters as 25 to 100, we shall have the height of the moon's shadow in the same circumstances, above 61 semidiameters of the earth.

Hence, as the moon's least distance from the earth is scarce 50 semidiameters, and the greatest not more than 64;

Vol. II. N° 108.

the moon, when in opposition to the sun, in or near the nodes, will fall into the earth's shadow, though the sun and moon be in their apogees; and much more, if they be in or near their perigees; because the shadow is then longer, and the moon nearer the base of the cone.

2. To find the apparent semidiameter of the earth's shadow, in the place of the moon's passage, for any given time. Find the sun and moon's distance from the earth, and thence their horizontal parallaxes; add the parallaxes together, and from the sum subtract the apparent semidiameter of the sun; the remainder is the apparent semidiameter of the shadow.

Thus, suppose the moon's horizontal parallax $59^{\circ} 18'$, the sun's $9^{\circ} 15'$; also the sun is $53^{\circ} 27'$ from which if the sun's apparent semidiameter $16^{\circ} 5'$ be subtracted, we shall have $41^{\circ} 27'$ for the semidiameter of the shadow.

Note, M. De la Hire omits the sun's parallax, as of no consideration; but increases the apparent semidiameter of the shadow by a whole minute, for the shadow of the atmosphere; which would give the semidiameter of the shadow, in our instance, $42^{\circ} 13'$.

3. The moon's latitude, *AL*, at the time of her opposition, together with the angle at the node *B*, being given; to find the arch between the centres *AI*, and the arch *LI*. (fig. 35.) Since in the spherical triangle *ALI*, rectangular at *I*, the side *AL* is given; as also the angle *ALI*, which is the complement of *LAI*, or *B*, to a right angle; the arch between the centres *AI*, is found by spherical trigonometry; and since the angle *LAI* is equal to *B*, each of them, with *IAB*, making a right angle; and the moon's latitude *AL* is given; the arch *LI* will likewise be found by spherical trigonometry. See SPHERICAL triangle.

ECLIPSE of the moon to determine the bounds of an. Since there is no eclipse possible, but when the aggregate of the semidiameters of the shadow and the moon is greater than the moon's latitude (for, without this, the moon will not come in the shadow) and the apparent semidiameters of the moon in perigee, and of the shadow, supposing the sun in apogee; by which you will have the side *MO*, (fig. 36.) Then, in the spherical triangle *MNO*, having given the angle at the node, whose quantity is the moon's greatest latitude in the conjunction; the right angle *M*, and the leg *MO*; find the moon's distance from the node *NO*; which is the utmost bound, beyond which the eclipse cannot reach. After the same manner, adding the apparent semidiameters of the moon in apogee, and of the shadow of the earth when the sun is in perigee, for the sake of having the side *LH* in the triangle *NLH*, the distance of the moon, from the ascending node *HN*, will be found by spherical trigonometry; which is the bound within which the moon will necessarily be eclipsed.

Thus, e. g. the semidiameter of the shadow, when the sun is in apogee, and the moon in perigee, according to Kepler, is $49^{\circ} 40'$. And the apparent semidiameter of the moon in perigee, $16^{\circ} 32'$. Consequently *MO* is 66° , or $1^{\circ} 6'$; and therefore there will be no eclipse at all, if the moon's latitude be greater than $1^{\circ} 6'$. Now, as the same angle *N* is supposed by Kepler to be $5^{\circ} 18'$,

Log. sin. N $8,9655337$

Sin. MO $8,2832433$

Whole sine $10,0000000$

Log. of sine ON $9,3177096$

The number corresponding to which in the tables is $11^{\circ} 50' 50''$. If, therefore, the moon's distance from either of the nodes be greater than 12° , no eclipse will generally happen. And, in like manner, the semidiameter of the shadow in the sun's perigee, and the moon's apogee, is $45^{\circ} 30'$, and the moon's semidiameter in her apogee $15'$. Consequently *LH* is $53^{\circ} 50'$. And therefore there will be an eclipse, if the moon's latitude doth not exceed $15^{\circ} 50'$. This, however, admits of some variation; for when the full moon is in her apogee, she will be eclipsed, if she be within $10\frac{1}{2}$ degrees of the node; and when she is full in her perigee, she will be eclipsed, if she be within $12\frac{1}{2}$ of the node.

To determine the quantity of an eclipse, or the number of digits eclipsed.—Add the moon's semidiameter *IK* (fig. 35.) to the semidiameter of the shadow *AM*, then will *AM* + *IK* = *A1* + *IM* + *IK* = *A1* + *MK*. From this sum, therefore, subtract the arch between the centres *AI*, the remainder gives the scruples or parts of the diameter eclipsed *MK*. Say, therefore, as the moon's diameter *KI* is to the scruples or parts thereof eclipsed *MK*; so is 12 to the digits eclipsed.

To find the scruples of half duration of an eclipse, or the arch of the lunar orbit, which her centre describes from the beginning of the eclipse to the middle thereof. Add the semidiameters of the shadow *AP*, and the moon *PN* together; the sum

sum gives AN. From the square of AN subtract the square of AI; the remainder is the square of IN. And the square root of this residue is the arch IN required.

To find the *scorpus* of half duration of total darkness in a total eclipse. Subtract the moon's semidiameter SV (fig. 37.) from the semidiameter of the shadow AV; the remainder is AS: in the triangle AIS, which is rectangular at I, therefore, we have the arch AS given by the last method; and the arch between the centres AI; where the arch IS is found, as in the last problem.

To find the beginning, middle, and end, of a lunar eclipse. Say, as the moon's horary motion from the sun is to 3600 horary seconds; so are the seconds of the arch LI (fig. 35.) to the horary seconds equivalent thereto. Subtract these *scorpi* or seconds, in the first and third quadrant of the anomaly, from the time of full moon, and add it to the same in the second and fourth; the result is the time of the middle of the eclipse. Then say, as the moon's horary motion from the sun is to 3600 *scorpi*, or seconds, so are the seconds of half duration IN to the time of half duration; the double of which gives the whole duration. Lastly, subtract the time of half duration from the time of the middle of the eclipse, the remainder will be the beginning of the eclipse. And add the same to the same, the sum will be its end.

A lunar eclipse, that is both total and central, lasts 3 hours 57 minutes 6 seconds, from the beginning to the end, when the moon is in her apogee; and 3 hours 37 minutes 26 seconds, when in perigee; her horary motion being slower in the former case, and quicker in the latter.

To calculate an eclipse of the moon. 1. For the given time of the mean full moon, compute the moon's distance from the node, to find whether there be an eclipse or not; as taught in the first problem.

2. Compute the time of the true full moon, with the sun and moon's true place reduced to the ecliptic.

3. For the time of the true full moon, compute the moon's true latitude, and the distance of each luminary from the earth, with the horizontal parallaxes, and apparent semidiameters.

4. For the same time, find the sun and moon's true horary motion.

5. Find the apparent semidiameter of the shadow. And,

6. The arch between the centres AI, with the arch LI.

7. Compute the *scorpi* of half duration IN. And thence,

8. Determine the beginning, middle, and end, of the eclipse.

Lastly, Find the *scorpi* of the eclipse, and thence the quantity of the eclipse, as taught under the preceding problems.

To draw a type, or figure, of a lunar eclipse, as a plane. 1. Let CD (fig. 38.) represent the ecliptic; and let the centre of the shadow be in A, through which draw a right line GQ perpendicular to DC; and suppose D the east, C the west, Q the fourth, and G the north.

2. From A, with the interval of the aggregate AN, of the semidiameter of the shadow AP, and of the moon PN, describe a circle DGCQ; and with the interval of the semidiameter of the shadow AP, draw another concentric circle EPI, which will exhibit the section of the shadow in the passage of the moon.

3. Let AL be equal to the latitude of the moon at the beginning of the eclipse; and in L erect a perpendicular LN, meeting the greater circle in N, towards the west. Then will the centre of the moon, at the beginning of the eclipse, be in N.

4. After like manner, make AS equal to the latitude of the moon at the end of the eclipse; and in S erect a perpendicular OS, parallel to DC; then will the centre of the moon be in O, at the end of the eclipse.

5. Connect the points O and N by a right line; ON will be the arch of the orbit, which the centre of the moon describes during the eclipse.

6. From O and N, with the interval of the moon's semidiameter, describe circles PV and TX, which will exhibit the moon at the beginning and end of the eclipse.

7. Then, from A, letting fall a perpendicular AI to ON; the centre of the moon will be in I, in the middle of the darkness.

Wherefore, lastly, from I, with the interval of the moon's semidiameter, describe a circle HK; this will represent the moon in the greatest darkness, and at the same time the quantity of the eclipse.

ECLIPSE of the sun, is an occultation of the sun's body, occasioned by an interposition of the moon between the sun and the earth.

It is distinguished, like that of the moon, into *total* and *partial*, &c. to which must be added a third species called *annular*.

Eclipses of the sun, some authors observe, should in propriety be called eclipses of the earth.

As the moon is found to have a parallax of latitude, eclipses of the sun only happen when the latitude of the moon, viewed from the earth, is less than the aggregate of the apparent semidiameters of the sun and moon. Solar eclipses, therefore, happen when the moon is in conjunction with the sun, in or near the nodes, i. e. at the new moons. Consequently, the memorable eclipses of the sun, at our Saviour's passion, happening at the time of full moon, when the sun and moon are in opposition, was preternatural. Besides, the darkness in total eclipses of the sun never lasts above four minutes in one place; whereas the darkness of the crucifixion lasted three hours, Matt. xxviii. 15. and overspread, at least, all the land of Judea.

Though the new moon pass between the sun and the earth, yet is not there an eclipse every moon; because the moon's way is not precisely under the ecliptic, but is placed obliquely thereto; only intersecting it twice in every period. So that eclipses can only be occasioned in such new moons, as happen in these intersections or nodes, or very near them.

In the nodes, when the moon has no visible latitude, the occultation is total; and with some continuance, when the disc of the moon, in perigee, appears greater than that of the sun in apogee, and its shadow is extended beyond the surface of the earth; and, without continuance, at moderate distances, when the cusp, or point of the moon's shadow barely touches the earth. Lastly, out of the nodes, but near them, the eclipses are partial. The other circumstances of solar eclipses are, 1. That none of them are universal; that is, none of them are seen throughout the whole hemisphere, which the sun is then above; the moon's disc being much too little, and much too near the earth, to hide the sun from the disc of the earth.

The moon's dark shadow covers only a spot on the earth's surface, about 180 English miles broad, when the sun's distance is greatest, and the moon's least; and thus far only can the total darkness extend. In this case, if L (Tab. II. Astron., fig. 72.) represent the moon, T the centre of the earth, LT the distance of the moon, equal to 55 semidiameters of the earth, LM the height of the shadow of the moon, equal to 60; then will TB be to TM as 4 to 4, and as the sine of the angle TMB = $19^{\circ} 05'$ to the sine of the angle TBM; i. e. 6900, 80, 106020599; 76632959; 4465368, the sine of $6^{\circ} 20'$; therefore the arc AB, or the angle ATB = $\angle TMB + \angle TBM = 15^{\circ} 60' + 6^{\circ} 20' = 21^{\circ} 10'$; and the arc BC = $15^{\circ} 20' = 183$ miles. But her partial shadow, or penumbra, may then cover a circular space 4900 miles in diameter, within which the sun is more or less eclipsed, as the places are less or more distant from the centre of the penumbra. In this case the axis of the shade is supposed to pass through the centre of the earth, or the moon is supposed to change easily in the node; and then the section of the shadow will be evidently circular; but in every other case the conical shadow is cut obliquely, and the section will be an ellipse.

2. Nor does the eclipse appear the same in all parts of the earth, where it is seen; but when in one place it is total, in another it is only partial. Farther, when the moon, being in her apogee, appears much less than the sun, as happens most sensibly when he is in perigee; the cusp of the lunar shadow not reaching the earth, he becomes in a central conjunction with the sun, yet not able to cover his disc, but lets his whole limb appear like a lucid ring or bracelet; this is hence called an *annular eclipse*.

3. It does not happen at the same time in all places where it is seen; but appears more early to the western parts, and later to the eastern.

4. In most solar eclipses the moon's disc is covered with a faint, dawning light; which is attributed to the reflexion of the light from the illuminated part of the earth. Lastly, in total eclipses of the sun, the moon's limb is seen surrounded by a pale circle of light; which some astronomers take for a manifest indication of a lunar atmosphere; but which is probably the atmosphere of the sun; because it has been observed to move equally with the sun, and not with the moon; and besides, the moon is now generally believed to have no atmosphere.

ECLIPSE of the sun, the astronomy of. To determine the bounds of a solar eclipse.

If the moon's parallax were insensible, the bounds of a solar eclipse would be determined after the same manner as those of a lunar; but because here is a sensible parallax, we must alter our measures a little, viz.

1. Add the apparent semidiameters of the luminaries both in apogee and perigee together.

2. Since the parallax diminishes the northern latitude, to the former sum add the greatest parallax of latitude possible, and since the parallax augments the southern latitude,

side, from the same sum subtract the greatest parallax of latitude. Thus, in each case, will you have the true latitude, beyond which there can be no eclipse. This latitude given, the moon's distance from the nodes, beyond which eclipses cannot happen, is found, as already directed for *lunar eclipses*.

As different authors follow very different hypotheses, with regard to the apparent diameters of the luminaries, and the greatest parallax of latitude, they differ much in assigning the bounds at which *solar eclipses* happen. Ptolemy makes the utmost bound of eclipses at $10^{\circ} 25'$ distance from the node; Copernicus, at $10^{\circ} 12'$; Tycho, at $18^{\circ} 25'$; Kepler at $17^{\circ} 16'$; Ricciolus, at $18^{\circ} 49'$. Though Ptolemy, in other places, judges $16^{\circ} 43'$ minutes distance from the node, necessary; Copernicus, $16^{\circ} 25'$; Tycho, $17^{\circ} 9'$; Kepler, $15^{\circ} 55'$; and Ricciolus, $15^{\circ} 28'$.

Astronomers have generally assigned 17° as the limit of solar eclipses; but this admits of some variation; for in apogee eclipses, the solar limit is but $16\frac{1}{2}$ degrees, and in perigee eclipses it is $18\frac{1}{2}$.

To find the digits eclipsed. Add the apparent semidiameters of the luminaries into one sum; from which subtract the moon's apparent latitude, the remainder is the scruples, or parts of the diameter eclipsed. Then say, as the semidiameter of the sun is to the scruples eclipsed, so are 6 digits reduced into scruples, or 300 scruples, to the digits eclipsed.

To find the scruples of half duration, or the line of immersion. The method is the same as that delivered for *lunar eclipses*.

To determine the duration of a solar eclipse. Find the horary motion of the moon from the sun, for one hour before the conjunction, and another hour after; then say, as the former horary motion is to the seconds in an hour, so are the scruples of half duration to the time of immersion; and as the latter horary motion is to the same seconds, so are the same scruples of half duration to the time of immersion. Lastly, adding the time of immersion to that of emersion, the aggregate is the total duration.

The moon's apparent diameter when largest, exceeds the sun's when least, only 1 minute 38 seconds of a degree; and in the greatest solar eclipse that can happen at any time and place, the total darkness can continue no longer than while the moon is moving through $1^{\circ} 38'$ from the sun in her orbit, which is about 3 minutes 13 seconds of an hour: for the motion of the shadow on the earth's disk is equal to the moon's motion from the sun, which, on account of the earth's revolution on its axis towards the same way, or eastward, is about 304 minutes of a degree every hour, at a mean rate; but to much of the moon's orbit is equal to 304° of a great circle on the earth, because the circumference of the moon's orbit is 60 times that of the earth; and therefore the moon's shadow goes 304 degrees, or 1830 geographical miles in an hour, or 304 miles in a minute.

To determine the beginning, middle, and end of a solar eclipse. From the moon's latitude, for the time of conjunction, find the arch LL (fig. 33.) or the distance of the greatest obscuration. Then say, as the horary motion of the moon from the sun, before the conjunction, is to 3600 seconds of an hour; so is the distance of the greatest darkness, to the interval of time between the greatest darkness and the conjunction.

Subtract this interval, in the first and third quarter of the anomaly, from the time of the conjunction; and in the other quarters, add it to the same; the result is the time of the greatest darkness. Lastly, from the time of the greatest darkness, subtract the time of incidence, and add it to the time of emersion; the difference, in the first case, will be the beginning; and the sum, in the latter case, the end of the eclipse.

Indeed, as the interval between the conjunction, and the greatest obscuration, is very small, and exceedingly precarious, it is not necessary to be so very precise; and accordingly, many authors use the time of the apparent conjunction for that of the greatest darkness.

Or if you would determine it with more accuracy, subtract about two minutes for the distance between the conjunction seen, and the time of the greatest obscuration.

To find the moon's apparent latitude at the beginning and end of an eclipse. From the argument of the moon's latitude, computed for the time of the apparent conjunction, subtract the scruples of half duration, together with the motion of the sun, answering to the time of incidence; the remainder is the argument of latitude, at the beginning of the eclipse.

To the same sum add the same scruples, together with the sun's motion answering to the time of emersion; the aggregate is the argument of latitude, at the end of the eclipse. The argument of the latitude given, the

moon's true latitude is found after the common manner. See LATITUDE. And from the true latitude, is found the apparent one.

The apparent latitude of the moon, at the beginning and end of a solar eclipse, given, to draw a type or figure thereof. This is performed, as already taught for eclipses of the moon.

Eclipse of the sun, to calculate on. 1. Find the mean new moon, and thence the true one; together with the place of the luminaries for the apparent time of the true one.

2. For the apparent time of the true new moon, compute the apparent time of the new moon observed.

3. For the apparent time of the new moon seen, compute the latitude seen.

4. Thence determine the digits eclipsed.

5. Find the times of the greatest darkness, immersion, and emersion.

6. Thence determine the beginning, and ending, of the eclipse.

From the preceding problems it is evident, that all the trouble and fatigue of the calculus arise from the parallaxes of longitude and latitude; without which, the calculation of solar eclipses would be the same with that of lunar ones. But after all that is here said, it will be found impossible to calculate any eclipses, either of the sun or moon, without having a book of the tables for that purpose, and precepts showing how to compute by them. See such tables and precepts in Ferguson's Astronomy, chap. xix.

In the Philosophical Transactions, N^o 461. sect. 9. we have a contrivance to represent solar eclipses, by means of the terrestrial globe, by M. Seeger, professor of mathematics at Gottingen. And Mr. Ferguson has fitted a terrestrial globe, so as to shew the time, quantity, duration, and progress of solar eclipses, at any place of the earth where they are visible. This he calls the ACTUATION. He has also given a large catalogue of ancient and modern eclipses, including those recorded in history, from 721 years before Christ, to A. D. 1485; computed eclipses from 1485 to 1700, and all the eclipses visible in Europe from 1700 to 1800. Astron. p. 175, &c.

ECLIPSES, the number of, of both luminaries, in any year, cannot be less than two, nor more than seven; the most usual number is four, and it is rarely more than six. The reason is obvious; because the sun passes by both the nodes but once in a year, unless he passes by one of them in the beginning of the year; in which case he will pass by the same again a little before the year be finished; because the nodes move backwards $19\frac{1}{2}''$ every year, and therefore the sun will come to either of them 173 days after the other. And if either node is within $17'$ of the sun at the time of the new moon, the sun will be eclipsed; and at the subsequent opposition, the moon will be eclipsed in the other node, and come round to the next conjunction before the former node is $17'$ beyond the sun, and eclipse him again. When three eclipses happen about either node, the like number generally happen about the opposite; as the sun comes to it in 173 days afterwards, and six lunations contain only four days more. Thus there may be two eclipses of the sun, and one of the moon, about each of the nodes. But if the moon changes in either of the nodes, she cannot be near enough the other node at the next full to be eclipsed; and in six lunar months afterwards she will change near the other node; in which case there can be only two eclipses in a year, both of the sun.

ECLIPSES, period of, is that space of time in which the same eclipses return again; and, as the nodes move backward $19\frac{1}{2}''$ every year, they would shift through all the signs and degrees of the ecliptic in 18 years and 225 days; this would be the regular period of their return, if any complete number of lunations were finished without a fraction; but this is not the case. However, in 223 mean lunations, after the sun, moon, and nodes, have been once in a state of conjunction, they return to nearly to the same place again, as that the same node, which was in conjunction with the sun and moon at the beginning of the first of these lunations, will be within $28' 12''$ of a degree of a line of conjunction with the sun and moon again, when the last of these lunations is completed; and in this period there will be a regular return of eclipses for many ages. By adding to the mean time of any solar or lunar eclipse this period, or 18 Julian years 11 days 7 hours 43 minutes 20 seconds, when the last day of February in leap years is four times included, or a day less, when it occurs five times, we shall have the mean time of the return of the same eclipse. In an interval of 6890 mean lunations, containing 557 years 31 days 18 hours 30 minutes 12 seconds, the sun and node meet so nearly, as to be distant only 11 seconds.

ECLIPSES, size of. In Astronomy, eclipses of the moon determine the fabrical figure of the earth, and also that the sun is bigger than the earth, and the earth than the

moon. *Eclipses* also, that are similar in all circumstances, and that happen at considerable intervals of time, seem to ascertain the period of the moon's motion. In Geography, *eclipses* discover the LONGITUDES of different places; for which purpose those of the moon are the most useful, because they are more frequently visible, and the same lunar *eclipse* is of equal magnitude and duration at all places where it is seen. In Cosmography, both solar and lunar *eclipses* serve to determine exactly the time of any past event.

ECLIPSES of the satellites. See SATELLITES of Jupiter.

The chief circumstances here observed are, 1. That the satellites of Jupiter undergo two or three kinds of *eclipses*; whereof, the first are proper, being such as happen when Jupiter's body is directly interposed between them and the sun; these happen almost every day. Mr. Flamsteed, and Cassini, give us tables, wherein immersions into Jupiter's shadow, and emersions again, are computed to hours and minutes.

The second are occultations, rather than obstructions; wherein the same satellites, coming too near to Jupiter's body, are lost in his light; which Riccioli calls *occiditae nebulae, setting invisibly*. In which case, Jupiter's nearest satellite exhibits a third kind of *eclipse*; being observed like a macula, or dark round spot, transfixing Jupiter's disc, with a motion contrary to that of the satellite; just as the moon's shadow projected on the earth, will appear to do, to the lunar inhabitants.

The *eclipses* of Jupiter's satellites furnish the best means of finding the longitude at sea. Those, particularly, of the first satellite, are much surer than the *eclipses* of the moon, and they also happen much oftener; beside that, the manner of applying them is very easy. See LONGITUDE.

ECLIPSE, ECLIPSE, something belonging to eclipses.

All new and full moons are not *eclipses*, i. e. eclipses do not happen every new and full moon, though there be then an interposition, either of the earth between the sun and moon, or of the moon between the sun and earth. The reason is, that the interposition is only as to longitude, and not as to latitude. The sun is always in the *eclipse*, but the moon is not; it deviates from it above five degrees, and, sometimes on the north side, and sometimes on the south. But every five months, or thereabouts, the cuts the *eclipse*; and it is only about those times, that there can be eclipses either of the moon or sun.

The places wherein the cuts the *eclipse*, are called the *nodes* of the moon.

ECLIPSE, bounds, or limits, are the greatest distances from the nodes at which the sun and moon can be eclipsed; namely, between 17 and 18 degrees for the sun, and 12 for the moon.

ECLIPSE, digits, digits eclipsed. See DIGITS.

Eclipse is more particularly used for a line, or circle, in the sphere of the stars, under which the centre of the sun apparently proceeds in its proper motion; or a line, which the sun's centre describes in his annual progress. It has its name *eclipse*, because all eclipses happen when the two planets are in or near the nodes, or interpositions of the eclipses.

It is also called the *sun's orbit*, and *sun's way*, because the sun never deviates from it, in his apparent annual motion from west to east.

The north, or ascending node of the *eclipse*, is called the *dragon's head*; and the south, or descending node, the *dragon's tail*.

The *eclipse* is placed obliquely with respect to the equator, and cuts it in two points, viz. the beginning of Aries and Libra, which are directly opposite to each other; and, accordingly, we find the sun twice every year in the equator; and all the rest of the year, either on the north or south side thereof.

The *eclipse* is a great circle of the sphere, bisected by the horizon; consequently, the arch of the *eclipse*, intercepted between the horizon and the meridian, is a quadrant. And again, the solstitial points of the *eclipse*, i. e. those most remote from the equator, are a quadrant distant from the equinoctial points. Lastly, as the point of the *eclipse*, which has the greatest declination, with respect to the equator, is distant by a quadrant from the equinoctial point; the distance of this point from the equator will be the measure, or quantity, of the obliquity of the *eclipse*, i. e. of the angle, formed by the intersection of the equator with the *eclipse*.

The obliquity of the *eclipse*, or the angle it makes with the equator, is about $23^{\circ} 28'$; which, therefore, is the greatest declination of any point of the *eclipse* from the equator; the points of which greatest declination on each side, are called the *solstitial points*; through which are drawn the two tropics, parallel to the equator.

The method of observing the greatest declination of the *eclipse* is thus: about the time of the summer solstice observe the sun's meridian altitude with the utmost care, for several days successively; from the greatest altitude observed, subtract the height of the equator; and the remainder is the greatest declination, which is the solstitial point.

Or, it may be found by observing the meridian altitude of the sun's centre on the days of the summer and winter solstice; the difference of those altitudes will be the distance of the tropics; and half that distance will be the obliquity of the *eclipse*.

Riccioli, e. gr. at Bologna, in the year 1646, observed the sun's meridian altitude, on the 20th of June, to be $68^{\circ} 59' 55''$; on the 21st, $69^{\circ} 0' 10''$; and on the 22d, $68^{\circ} 59' 55''$. The greatest then was, $69^{\circ} 0' 10''$; from which the altitude of the equator, $45^{\circ} 29' 50''$, being subtracted, left $23^{\circ} 30' 20''$ for the greatest declination.

It has been matter of great dispute among the late astronomers, whether the obliquity of the *eclipse* be fixed or variable. To determine the point, the observations of the astronomers of all ages have been collected together, the chief of which may be seen in the following table.

Author's Names	Years before Christ	Obliquity
Eratosthenes and Hipparchus	230 and 140 after Christ	23 49 23 23 51 20

Riccioli Alm. vol. i. lib. iii. cap. 27. Ptolem. Alm. lib. i. cap. 10. Flamsteed Proleg. Hist. Cael. vol. iii. Phil. Trans. N^o 163. Ib. vol. xliii. part. i. p. 125. Naut. Alm. 1779. Long's Afr. vol. i. cap. 16.

Upon the whole, as the oldest observations make the obliquity the greatest, it appears to be mutable, and in a constant decreasing state. The chevalier de Louville, who has examined the merits of the cause with great attention, and made allowances for refraction and sun's parallax, is of the same opinion. He gives us the result of his researches in the Memoirs of the Royal Academy, for the year 1716, viz. that the obliquity of the *eclipse* diminishes at the rate of a minute in 100 years. His dissertation is published in Latin in the Acta Erud. Lipsiæ, A. D. 1719.

According to an ancient tradition of the Egyptians, mentioned

mentioned by Herodotus, the *obliquity* had formerly been perpendicular to the equator: this notion they were led into, by observing, for a long series of years, that the obliquity was continually diminishing; or, which amounts to the same, that the *obliquity* was continually approaching to the equator. From hence they took occasion to suppose, that these two circles, in the beginning, had been as far off each other as possible. Dioid. Siculus relates, that the Chaldeans reckoned 40200 years from their first observations, to the time of Alexander's entering Babylon. This enormous account may have some foundation, supposing the Chaldeans to have built on the diminution of the obliquity of the *obliquity* a minute in 100 years. M. de Louville, taking the obliquity such as it must have been at the time of Alexander's entrance into Babylon, and going back to the time when the *obliquity*, at that rate, must have been perpendicular to the equator, actually finds 402942 Egyptian, or Chaldean years, which is only 58 years short of the former epocha. In the general, there is no way of accounting for the fabulous antiquity of the Egyptians, Chaldeans, &c. so probable, as from the supposition of long periods of very slow celestial motions, whereof they had observed a little part, and thence calculated the beginning of the period; making the world and their own nation to commence together. If M. de Louville's system be true, in 140000 years more the *obliquity* and equator must coincide.

Godin, in the Memoirs of the Royal Academy for 1734, rejects the conclusions deduced by Louville from the observations of ancient astronomers, and, by comparing those of Cassini in 1655, which give the obliquity of the *obliquity* $23^{\circ} 29' 15''$, with others made at Paris, and elsewhere, since the year 1730, which make the obliquity no more than $23^{\circ} 28' 20''$, he infers, that it diminishes at the rate of $55''$ in 80 years, or nearly at the rate of $1''$ in 90 years.

Mr. Harnby, comparing the result of his own observations, which gives the mean obliquity in 1772, $23^{\circ} 28' 6''$, with the mean obliquity assigned by Mr. Flamsteed in 1690, viz. $23^{\circ} 28' 55.5''$, concludes, that the obliquity has diminished $47''$ in 81 years, or at the rate of $58''$ in 100 years; which, he observes, will be found nearly to correspond with the mean of the computations framed by Mr. Euler, and Mr. de la Lande, upon the principles of attractions. Other writers have made it still less. Phil. Trans. vol. lxiii. part i. p. 125.

However, M. Cassini, and M. le Monnier, are of opinion, that the obliquity of the *obliquity* hath no other variation than what the mutation of the earth's axis will occasion. Mem. R. Acad. 1762, & 1767.

But there is reason to believe, by comparing the more accurate observations in the preceding table, e. g. those of Ptolemy, Tycho, Flamsteed, Mayer, and Bradley, that the obliquity of the *obliquity* does gradually decrease, and probably at the rate of about half a second in a year. And if we consider, that the earth is not a perfect sphere, but an oblate spheroid, having its axis shorter than its equatorial diameter; and that the sun and moon are constantly acting obliquely upon the greater quantity of matter about the equator, drawing it, as it were, to a nearer and nearer coincidence with the *obliquity*; it will not appear improbable that these actions should gradually lessen the angle between the planes of these circles. Nor is it less probable, that the mutual attraction of all the planets should have a tendency to bring their orbits to a coincidence, though the change, being very small, is not sensible for many ages. See NUTATION, PRECESSION, and STAR.

The *obliquity* is divided into twelve parts, called *signs*. See SIGN.

ECLIPSE, poles of the. See POLE.

ECLIPSE, reduction to the. See REDUCTION.

ECLIPSE, in Geography, &c. is a great circle of the globe, cutting the equator under an angle of $23^{\circ} 28'$. See GLOBE.

The terrestrial *obliquity*, therefore, is in the plane of the celestial *obliquity*, like which it has its equinoctial and solstitial points, and is bounded by tropics.

ECLOGARI, among the *Ancients*, were persons who selected the best pieces of the books they read, which, for that reason, were called *eclogues*, or select pieces. See ECLOGUE.

ECLOGUE, BACON, in Poetry, a kind of pastoral composition wherein shepherds are introduced conversing together. The *eclogue* is properly an image of the pastoral life.

The beauty of the *eclogue*, M. Fontenelle observes, is not attached to what is rural, but rather to what is calm and easy in the rural life.

Yet there are *eclogues* in Theocritus of a lofty character; and Virgil has some in the sublime style: the *eclogues*, therefore, occasionally raises its voice. Yet M. Fontenelle observes it a fault in some modern poets, to have

Vol. II. N^o 108.
